A total of 1,654 comments were classified as supporting another alternative. Almost all asked for Alternative G or higher, with only a few requests for Alternative B or E. Over 82 percent of the comments received were form emails that stated:

- “EPA should select Alternative G with additional dredging in areas of high human use, areas of high ecological value, and areas where there is high risk of recontamination of the river.”
- “Recommend that EPA select Alternative "G," with modifications of additional dredged acreage recommended by the Audubon Society of Portland”
- “I support Willamette Riverkeeper’s position that the Portland Harbor Superfund Site needs an aggressive clean up that protects people and wildlife for the long term.”

The remaining comments were personal comments that included:

- “Alternatives G and H seem better than I. Alternative I is simply a Band-Aid approach and will achieve very little. It is understood that alternatives H and G will take longer and be more expensive or "less cost effective", as the report states but the result will come much closer to achieving the restoration goal. As stated earlier, this section of the river took industry a long time to degrade and much profit was made in doing so. It is only fair and equitable that some of this time and profit be returned to make this area right for the people of Portland and the Pacific Northwest.”
- “Option I does not go far enough. Option G is the minimum level of clean-up necessary, with at least halfway between option G and option H being preferred. We are responsible to future generations to clean this river back to a pre-polluted state. Today’s presenter spoke of a reasonable time frame as a consideration. It took 100 years for the river to accumulate this

contamination. The longest projection for cleanup (option H) suggests it could take over half that time (62 years) to remove it. While it may seem long, in context it is no unreasonable. Option G is projected to take 19 years, which would clean the river in less than a fifth of the time we've taken to pollute it. That is reasonable (far more reasonable than allowing it to remain in our river)."

- "Alternative E includes dredging about 40 more acres in SDU 6 Nav than the proposed Alternative I. I would prefer EPA's final plan should include this additional 40 acres of dredging. Removing this material would result in the Hazard Index for the area due to PAHs being lowered to 3, rather than at 5 in the proposed plan alternative I."
- "I am a midwife. The chemicals cause prematurity, low birth weight, birth defects, and learning disabilities. Save our children - Option G - Please."
- "Really. Lame-sauce dude! Do next to nothing? Bologna. Option G+ for the Willamette Superfund."
- "Please consider a speedier and more effective plan that could impact our local environment in a huge and positive direction. We as Portlanders need to set an example and practice our sustainable, green reputation and do something extraordinary for the fish, wildlife and our next generation. Thank you for reading and considering this important alternative and support Alternative G."
- "Please select Alternative G with additional dredging as proposed by the Portland Audubon Society. This is our chance to do it right. The Willamette River has been ruthlessly used/abused by a long list of polluters including ExxonMobil, Northwest Natural and the Port of Portland. A partial clean-up is not adequate and does not serve the citizens adequately. We want our river back. It is vital to the health of our communities, our environment and our wildlife. This can only be accomplished by selecting Alternative G with additional dredging as proposed by the Portland Audubon Society."
- "In sum, the Oregon Chapter of the Sierra Club believes that Alternative G offers the best and most effective remediation of the Portland Harbor Superfund Site, short of complete removal of all contaminated sediment. We therefore recommend the adoption of Alternative G with enhancements to further protect health and the environment and ensure the long-term effectiveness of the cleanup."
- "According to the Plan, EPA found that all remedial alternatives except Alternative A would be protective of human health (Plan, p. 50.), but rejected Alternative B as too slowly protective of the environment (Plan, pp. 50 – 51). But because "none of the alternatives address all ecological risks" (Plan p. 60), the advantages of Alternative B, as the fastest and cheapest alternative with the least in-river construction, may exceed its disadvantages."

### **EPA Response**

EPA shares commenters' concerns about providing for a remedy that addresses risks to the health and well-being of everyone who lives near or uses the Willamette River as well as protection of fish, wildlife, and other organisms in the waterway in a timely manner. EPA has sought in its selected remedy (Alternative F Modified) to provide the best balance of achieving the most reduction in risk to people and aquatic organisms through a protective cleanup while reducing short-term impacts to the environment, the community, and workers during and after construction.

Many of the commenters stated a concern that the preferred alternative in the proposed plan (USEPA 2016c) did not involve enough dredging—that more dredging should be selected instead to reduce time to achieve cleanup goals and allow fish consumption advisories to be lifted sooner. Many commenters asked that EPA select at least Alternative G, Alternative G+, or Alternative H. Due to the vast majority of commenters' concern that the proposed plan left too much contamination for MNR as well as other issues raised with the proposed plan alternative, EPA has selected Alternative F Modified which will actively address an additional 103 acres of contaminated sediment. Therefore, selected remedy will remove up to 3 million cubic yards compared to approximately 1.75 million cubic yards of sediment than Alternative I. The selected remedy calls for the highest levels of contamination to be removed through dredging (roughly 3 million cubic yards) or to be isolated through capping (176 acres). ENR and MNR are employed only in areas with lower levels of contamination. EPA's analysis of alternatives shows that any larger, removal-based remedy beyond Alternative F Modified, such as Alternative G, would not substantially improve public health and environmental protection but would take a good deal longer, cost substantially more, have greater short-term impacts to aquatic organisms in the waterway and to the community surrounding the waterway because of dredging activity, and require the processing, transporting, and landfilling of millions of additional cubic yards of sediment with low levels of contamination.

In addition, Alternative G would impact the surrounding communities with substantially more traffic on the waterways, rails, and roads than the selected remedy. The potential for accidents, spills, and aquatic habitat disturbances from dredging and transporting such large volumes of contaminated sediment would be much greater for Alternative G than for the selected remedy.

It is important to note that an Alternative G+ was not identified nor evaluated in the feasibility study, so EPA cannot specifically comment on the merits of that alternative. However, EPA did evaluate a more aggressive dredging alternative than Alternative G (Alternative H), and the overall conclusions of the evaluation are similar to those for Alternative G but with even longer construction timeframes, larger negative short-term impacts including habitat losses during construction, and higher costs for the incremental additional risk reduction achieved. Alternative H would cost approximately 5 times more than Alternative G and would take 62 years to complete (compared to 19 years for Alternative G), with associated impacts to the community and potential releases to the environment for that period of time.

Dredging plays a significant role in the selected remedy but so do capping, MNR and ENR, based upon engineering considerations of site conditions (such as potential for erosion, sedimentation from upstream, and observed trends in natural recovery). The selected remedy in this ROD calls for the highest levels of contamination to be removed for upland disposal through dredging or to be isolated through robust capping that include components for in-place treatment. ENR and MNR are employed in areas with lower levels of contamination and conditions favorable for natural recovery to be effective at reducing contaminant levels and risk in a reasonable timeframe. Remaining risks to human health will be managed through ICs until cleanup levels and RAOs are achieved.

In response to the comment that said: "But because "none of the alternatives address all ecological risks" (Plan p. 60), the advantages of Alternative B, as the fastest and cheapest alternative with the least in-water construction, may exceed its disadvantages." EPA wants to point out that immediately after construction of the selected remedy, it is estimated that wildlife will be able to safely consume prey from within the Site since all non-cancer risks on a Site-wide scale will be addressed. It is estimated that BEHP will be at a HQ of 5 at a river mile scale and 3 at an SDU scale, very close to the target of 1 and well within potential calculation variances. For RAO 5, the interim target was 50 percent of the benthic risk

area. Thus, Alternatives D through G, including I and F Modified achieve the RAO 5 goal. For RAO 6, only Alternatives F, F Modified and G achieve the interim target.

### 2.31.2 Evaluate a Different Alternative for Swan Island

#### Comment Summary

Twenty-one comments were received as part of a form email stating:

- “Sediment should be removed from the Swan Island area rather than implementing a massive input of carbon.”

Two additional comments also addressed sediment removal at Swan Island:

- “Re: Swan Island Lagoon (p 60): Similar to comment #7 above, I would urge that EPA’s final plan include disrupting more benthic area and remove more than 50 percent of the risk from PCBs and Bphtalate.”
- “Recommendation for an Optimized Remedial Approach. In summary, the optimized remedy would provide for:
  - Dredging of sediments in the FMD to allow implementation of additional remedial technologies;
  - ENR with amendments as well as armoring to protect against propeller wash in the berth areas;
  - Assuming that future site investigation demonstrates no adverse propeller wash impacts and thus ENR permanence, ENR with amendments (GAC, for example) in the lagoon areas away from the berths;
  - Dredging of sediment in dry dock areas to adequate depth and placement of a residual layer where PCB concentrations in the leave surface exceed the RAL;
  - ENR with amendments in lagoon areas outside the FMD zone where PCB concentrations at the sediment surface exceed the RAL; and
  - Either MNR or ENR in areas outside the PCB RAL footprint, depending on the results of sampling and other studies performed during remedial design.”

#### EPA Response

In response to the comments seeking more dredging in Swan Island Lagoon, the selected remedy was chosen in order to provide a balance between minimizing the time required for remediation and implementing a suitably protective cleanup to minimize the risk to public health and the environment in the future, in an area where ENR is very likely to be highly effective. EPA has selected Alternative F Modified which will address an additional 37.7 acres of contaminated sediment in Swan Island Lagoon than Alternative I would have. After the remedy has been implemented, EPA will use sampling and monitoring results to guide and refine the cleanup action selected to provide additional assurance that the process is reducing contaminant concentrations and bioavailability as expected.

In response to the optimized remedial approach provided by a commenter, the selected remedy was chosen to provide a balanced approach in achieving remedial cleanup levels. The ROD includes a flexible decision tree which will dictate the design and remedial construction and is intended to provide a clear direction on what action should be taken under different conditions and locations.

## 2.32 Proposed Plan Content

### 2.32.1 Provide Capital Costs that Are Lacking in the Proposed Plan

#### Comment Summary

One commenter had specific concerns about the presentation of capital and periodic costs in the proposed plan, writing

- “Capital costs and periodic costs have not supporting documentation indicating how these costs were derived. No engineering duration or costs appear to be included in any of the alternatives. Construction durations have no supporting documentation indicating how those durations were established. Pg. 66 of the Plan states, “The technologies of dredging, capping, ENR and MNR have been demonstrated to be technically and administratively feasible at various other Superfund sites.” But the Plan provides no information about clean-up of other Superfund sites. Surely there have been other Superfund sites where at least some of the technologies EPA proposes have been used that would provide real historical data on the actual cost, duration, and effectiveness of these technologies to eliminate and/or contain contaminants in similar waterways. Without such supporting documentation, there is no substance to the data promoted in the alternatives EPA discusses. Please provide all case studies info. Without this data, the public has no way of providing intelligent feedback on this Plan.”

#### EPA Response

EPA has documented the methodology and assumptions used in developing various unit costs in Appendix G of the feasibility study report (USEPA 2016b). These unit costs were used to estimate capital costs and periodic costs in the detailed analysis cost estimates. The cost estimate backup as presented in Appendix G also includes Cost Source Database; EPA Derived Labor Costs; Project-Specific Vendor Quotes; Previously Developed Costs by Anchor QEA; EPA Derived MII Costs; and Costs from Other Projects/Sources. Also, Attachment A of Appendix G, presents further information about the development of the cost estimate.

During the feasibility study, a cursory evaluation of construction duration was performed for the major construction components (capping and dredging) as indicated in Appendix D.3 of the feasibility study report. A detailed construction schedule is generally not produced because the level of scope definition is too low to make those design-level determinations. It should be noted that schedules indicate a minimum duration and that longer durations only affect present value cost as estimated. The productivity rates presented in a memo from USACE (Palermo 2008) was used to calculate construction durations.

Where appropriate, information from other sediment cleanups or dredging sources were considered and used to prepare the feasibility study and in particular the cost estimates; however, cost estimates need to be site-specific and related to the remedial alternatives being compared for the particular circumstances at a site.

## 2.32.2 Address McCormick and Baxter Superfund Site Issues

### Comment Summary

Two commenters feel that cleanup work has not been adequately completed at the McCormick & Baxter Superfund Site and that additional cleanup work should be conducted as part of the Portland Harbor Superfund Site. The commenters wrote:

- “The McCormick & Baxter plant site has been frozen for several years. The current EPA process for that plant isolates it from the overall Portland Harbor process, but the site is listed in the plan. This separation only ensures that nothing more will be done but the plant site will continue to weep contaminants into the Willamette River. EPA should bring the site back into the Harbor process and as of 2016 reconsider the option of cleaning up the site, for potential reuse as riverside industrial property. The success of the Washington Department of Ecology and the Port of Ridgefield in “cleaning up” the Pacific Wood Treating provides a change in facts that deserves an EPA review and reconsideration, to protect the Willamette River and potentially reduce or remove the continuing expense of isolating the site.”
- “McCormick and Baxter Superfund Site. Even though this site has been somewhat completed; parts of it needs attention because it is still part of the Superfund site river bank.”

### EPA Response

The McCormick and Baxter Superfund Site is a former creosote wood treating facility that was listed on the National Priorities List (NPL) in 1994 where cleanup under a CERCLA ROD was completed in 2005 and is currently undergoing statutory five-year reviews to ensure the remedy remains protective. The Site consists of three OUs; OU1, OU2, and OU3 address the soil, sediment, and groundwater remedies, respectively. Cleanup included demolition of the McCormick & Baxter plant, excavation and treatment of contaminated soils, soil capping, sediment capping and construction of a subsurface barrier wall. While the McCormick and Baxter Site is located within the Portland Harbor Superfund Site, it is not included in the selected remedy for Portland Harbor because the sediment OU of the McCormick and Baxter Site remedy is completed, and monitoring indicates it is protective of human health and the environment.

The McCormick and Baxter Site will be monitored in perpetuity to ensure that it remains protective of human health and the environment. The most recent five-year review for McCormick & Baxter was completed in September 2016 (USEPA 2016e) which included close inspection and passive sampling of the in water sediment cap and determined that the soil remedy, sediment remedy, groundwater remedy, and engineering and ICs are functioning as intended by the 1996 ROD, as modified by the 1998 Amended ROD and the 2002 Explanation of Significant Difference. The five-year review further states there have been no changes in the physical conditions of McCormick & Baxter that would affect the protectiveness of the remedy. However, EPA determined that the groundwater cleanup levels as calculated for the McCormick and Baxter Site are not appropriate as substitutes for MCLs in groundwater. Therefore, the September 2016 five-year review determined that, in order for the remedy to be protective in the long term, the following actions need to be taken: formally replace the ACLs with revised cleanup goals and identify the associated points of compliance for the groundwater remedy in a ROD Amendment or ESD, and implement ICs required by the ROD for the groundwater remedy. EPA expects that those actions will be taken within the next five years. The next five-year review is required to be completed in September 2021.

### 2.32.3 Explain the Depiction of Groundwater Plumes in Proposed Plan

#### Comment Summary

A total of nine comments were received about issues with how groundwater was described in the proposed plan. Commenters had questions about Figure 5, specifically on how or why that figure was developed. They believed that the plumes on the figure were drawn much larger than they have previously been described at the Site, drawn to extend into the Willamette River, and/or are “cartoonish” in nature. Additionally, a three commenters noted that the COCs which compose the groundwater plumes are not described in the proposed plan.

#### EPA Response

Proposed plan Figure 5 (USEPA 2016c) is a modification of Figure 4.3 *Identified Groundwater Plumes January 2016* of the Portland Harbor Upland Source Control Summary Report (DEQ 2016). The groundwater plumes and associated COCs were identified by DEQ through their upland source control evaluations. Figure 5 presents a feasibility study level of understanding of the extent of COCs in groundwater potentially discharging to the Willamette River and was used to facilitate evaluation of remedial alternatives. The proposed plan did not describe in detail the nature and extent of contamination in each groundwater plume nor did it describe the source control measures implemented at each facility or site-specific pathways to the Willamette River. Such detail is available in facility-specific conceptual site models, which were developed under DEQ’s Upland Source Control Program. Groundwater plumes in each SMA will be further characterized during remedial design such that caps are appropriately amended as needed to meet cleanup levels.

### 2.32.4 Address the Groundwater Transport Mechanism

#### Comment Summary

Regarding groundwater transport, one commenter wrote:

- “The plan failed to mention the groundwater colloidal transport mechanism. This transport method is described as sorption of the dioxin/furans compounds onto organic carbon suspended in the groundwater. Carbon particles less than 0.7 microns in size are known to travel freely in aquifer matrices and the sorption of the dioxins/furans onto these particles may facilitate transport in groundwater. The groundwater flow characteristics need to be understood to predict when the contaminants will impact the river and those may occur over a longer time period than is normally associated with contaminant transport in groundwater. For this reason, Total Organic Carbon (TOC) analysis should be added to the groundwater monitoring program and aquifer characteristics such as gradient and transmissivity should be modelled to obtain estimates of dioxins/furans impacts to the river by this transport mechanism. Long-term monitoring programs may be needed to assess the significance of this transport mechanism in groundwater and to the river.”

#### EPA Response

Groundwater investigations are being conducted under oversight by the DEQ and vary from location to location. As a result, the exact parameters of any groundwater monitoring program are determined by DEQ based on site-specific conditions. However, groundwater investigations typically include estimates of hydraulic gradient and transmissivity. EPA will be working with DEQ to develop groundwater monitoring program requirements to ensure harbor-wide data needs and cleanup levels are being met. Additional information regarding the groundwater plumes is provided in Section 2.32.3 of this responsiveness summary.

### 2.32.5 Provide Information Lacking on Dioxin/Furan Data

#### Comment Summary

One commenter had specific concerns on dioxin and furan data provided in the proposed plan, writing:

- “Dioxins and furans are shown as contaminants of concern however the presentation of the data has not been adequately presented. The toxicity equivalence quotients data presented are high level summaries of the individual dioxins/furans compounds and adequate explanations as to how the data were compiled was not presented.”
- “The dioxins and furans analytical method information was not adequately presented (it should be added to the footnotes of the tables). Since there is a high resolution and a low resolution method associated with the dioxins/furans analysis, this can potentially cause misinterpretations of the data. For example, a non-detection "ND" using the low resolution method may be significantly elevated compared to a ND for the high resolution method. This topic does not appear to have been mentioned and it can cause significant misinterpretations of the data (e.g. for example possibly 200-fold difference). Add notes to explain the methods associated with the analytical methods. ND's by the low resolution method should be qualified and not haphazardly combined using the toxicity equivalence quotient method with results from the high resolution method.”
- “Where the study relies on the low resolution mass spectroscopy method, the data set should be supplemented with additional collection of samples and testing with the high resolution method to confirm the results (in situations where NDs occurred, they should be verified by the high resolution method).”

#### EPA Response

Dioxin and furan data are presented in the remedial investigation (*RI\_BERA20110727+RA-SummedParams.mdb*) and feasibility study (*LWGFSdbwEECA\_GASCOandArkema.accdb*) databases for the Site and is available as part of the administrative record. These databases include results for individual dioxin and furan congeners as well as dioxin homologs and dioxin as 2,3,7,8-TCDD toxicity equivalent quotients. As the commenter notes, both high and low resolution methods were used for certain analyses such as PCB Arcolor and PCB congener analysis. Early in the remedial investigation, detailed criteria for selection of values from multiple results for the same chemical in a sample were developed. Also, approximately 30 percent of the low resolution total PCB Aroclor analyses were supplemented by high resolution congener analysis. In addition to these measures, EPA developed the Round 2 Quality Assurance Project Plan in June 2004 (Integral and Windward 2004) and subsequent addendums to ensure data quality adequate for remedial investigation, feasibility study, proposed plan (USEPA 2016c) and the ROD. As a result, these data are considered adequate for remedial decision making. In addition, more detailed data will be collected for the remedial design phase.

### 2.32.6 Explain Why Mercury is Not Included in the Description of Risk Reduction

#### Comment Summary

A comment was received that stated “EPA must correct the understanding regarding fish advisories and revise the proposed plan to expressly reference the impact of mercury and other relevant watershed-wide contaminants and present a more complete and frank assessment as to the actual likelihood of advisories being lifted for each remedial alternative. Only then will the public be able to provide more meaningful comments on these issues and evaluate the actual costs and benefits of each alternative.”

**EPA Response**

The topic of mercury contamination (site-wide and beyond) has been discussed previously with the public at multiple working groups and public meetings. EPA's remedy is addressing releases of hazardous substances from facilities associated with the Portland Harbor Site and the alternatives evaluated and proposed plan (USEPA 2016c) is focused on that goal. As discussed in Section 2.3.2 of this document, fish consumption advisories will be less restrictive once the cleanup has been completed. However, EPA agrees that fish consumption advisories likely will not be lifted completely due to larger watershed issues (such as mercury) and also because concentrations of PCBs in "clean" areas upstream of Portland Harbor are higher than the acceptable range based on conservative risk estimates, and sediments naturally move downstream.

Over time, it is expected that source control actions on the part of DEQ in Portland Harbor and watershed-wide (including upstream areas) will reduce or eliminate the need for fish consumption advisories. In addition, as part of the selected remedy EPA will implement a communication outreach program to inform the public throughout the remediation regarding levels of contamination in fish/shellfish and how much fish is safe to eat.

**2.32.7 Explain Why PTW Figures Are Different****Comment Summary**

The footprints of PTW – Not Reliably Contained in the feasibility study report, Figure 3.2-5 and the proposed plan, Figure 7, are different.

**EPA Response**

EPA inadvertently used the wrong data set to map the PTW-NRC (naphthalene) footprint along the offshore of NW Natural to create Figure 7 of the proposed plan (USEPA 2016c). This figure has been updated to correct the PTW-NRC footprint (as presented in Figure 3.2-5 of the 2016 feasibility study report (USEPA 2016b)) in the ROD.

**2.32.8 Provide Studies of Technology Use at Other Superfund Sites****Comment Summary**

One person commented that "Pg. 66 of the Plan states, "The technologies of dredging, capping, ENR and MNR have been demonstrated to be technically and administratively feasible at various other Superfund sites." But the Plan provides no information about clean-up of other Superfund sites. Surely there have been other Superfund sites where at least some of the technologies EPA proposes have been used that would provide real historical data on the actual cost, duration, and effectiveness of these technologies to eliminate and/or contain contaminants in similar waterways. Without such supporting documentation, there is no substance to the data promoted in the alternatives EPA discusses. Please provide all case studies info. Without this data, the public has no way of providing intelligent feedback on this Plan."

**EPA Response**

Proposed plans are summary documents designed to be easily readable by the public. As such, the level of detail required in the proposed plan for the Site (USEPA 2016c) does not support the inclusion of case studies on specific technologies. The feasibility study alternative screening and evaluation process used those data extensively in the alternative development and evaluation process. The feasibility study report (USEPA 2016b) includes where appropriate information on similar sites was used in discussion of applicable technologies.

## 2.33 Human Health Risk

### 2.33.1 Evaluate Existing Exposure From PCBs in Air

#### Comment Summary

A total of 41 comments were received on this topic, with roughly 36 percent received as form emails that stated:

- “Include atmospheric transport in analysis of exposures. This inclusion will indicate the extent to which remaining contamination will expose humans in the community to unacceptable risks.”

The remaining comments were similar in content and most people seemed to be concerned primarily about the risk from volatilization of PCBs under existing conditions. Several people stated that PCB volatilization had not been included in any part of the EPA analysis or proposed plan and that recent studies existed showing that PCBs in sediments could volatilize and result in unacceptable releases to the atmosphere without the added disturbance of construction.

Representative comments include:

- “Air volatilization of PCBs needs to be a consideration for removal of a larger volume of sediment. Dr. David Carpenter’s studies have shown that residents living within 5 miles of a water Superfund site are adversely effected by PCB exposure.”
- “New information about volatilization of PCBs needs to be included. The latest information about volatilization of PCBs needs to be examined as a pathway of contamination to humans and the environment as part of the process to evaluate both human health and ecological risk.”
- “Dr. Peter deFur recently reviewed the proposed plan and stated that, quote, “Atmospheric release of PCBs is not included in any part of the EPA analysis or the proposed plan. Recent research confirms that PCBs can be released into the air, that air can be a source of human exposure, and that exposure by inhalation can cause harmful health effects in people.”
- “EPA fails to analyze the potential of atmospheric transport of PCBs as a potential exposure pathway in either the clean-up plan or the feasibility study. This is a significant omission in EPA’s analysis. The CAG’s comments provide an extensive discussion of the scientific literature supporting the need to analyze this risk. We urge EPA to include a robust analysis of the risk vaporization of PCBs and address it as appropriate in the final plan and ROD.”
- “PCBs are of particular concern because of air disposition, with people living within 5 miles of a PCB contaminated body of water showing elevated levels of PCBs in their bodies. (see Carpenter/New Bedford, MA)”
- “You have ignored volatilization of PCBs - Cadument had a school and a neighborhood who were made very ill due to PCB air volatilization blowing over them. We do not want this, please monitor appropriately.”
- “The City has heard concerns from the public related to the potential for air toxics from the release into the air of contaminants found in the sediment. Due to community concerns, please address the potential for volatilization of PCBs from sediment.”

- “In 1976, the Toxic Substance Control Act gives you, the EPA, authority to restrict PCBs from our environment. The current plan does not provide an adequate level of protection from the known health risks to our citizens from PCBs. Literature provides abundant documentation of the health-related problems from PCBs. Infants are exposed to PCBs through breast milk, and even before birth through transplacental transfer. As far back as 1996, The New England Journal of Medicine reported intellectual impairment of children exposed to PCBs, with lower cognitive ability, immune compromise, and motor control problems. In 2013, the International Agency for Research on Cancer reported evidence supporting cancer-causing effects from PCBs. Adults can suffer from severe hormonal disruption which affects metabolism and reduced immunity.”
- “In a study I just learned of Scientists Linking Autism to PCBs and Other Chemicals it was determined that two compounds in -- PCB 138/158 and PCB 153 -- stood out as being significantly linked with autism risk when their mothers are exposed during the second trimester of pregnancy. As we’ve learned, PCBs become air born and therefore have a huge risk potential for people living near the River. I and some other volunteers are hoping to petition the CDC for a human health study for these kinds of risks related to the superfund.”

Comments received related to implementing the cleanup safely during construction (through monitoring and use of best management practices) are addressed in Section 2.29 of this responsiveness summary.

### **EPA Response**

The baseline human health and ecological risk assessments for the Site identified exposure pathways to be evaluated quantitatively. As described in Section 3.3 of the human health risk assessment (Kennedy/Jenks Consultants. 2013), exposure pathways were characterized as potentially complete, potentially complete but insignificant, incomplete or potentially complete but evaluated for a different receptor. Consistent with EPA risk assessment guidance, inhalation of contaminants released from sediment was not identified as a complete exposure pathway to be quantitatively evaluated in the human health risk assessment. Specifically, PCBs are not expected to volatilize significantly from sediment due to their low vapor pressure. Human health risk assessments conducted on the Hudson River in New York, where PCB concentrations are much higher than they are in Portland Harbor, concluded that the calculated cancer risk from the inhalation of volatilized PCBs was insignificant (TAMS and Gradient 2000). Inhalation of volatile organic compounds released from surface water was considered a potentially complete but insignificant exposure pathway for all receptors.

The highest surface concentrations at the Site are in the 1 to 35 parts per million range, most of which are to be removed by dredging or sequestered by capping leaving no possibility of long-term emissions to air. Due to their hydrophobic tendency, the highest fraction of PCBs in the system will exist within the sediment and less so within the water and air. Fundamentally, it is this property that causes these COCs to accumulate in river sediments and also makes them unlikely to volatilize into the atmosphere. Continuous release of PCBs to the air is not expected and has not been documented at other similar sediment sites.

Due to the conclusions of the Hudson River study and the relatively low concentrations of PCBs in Portland Harbor, exposure due to inhalation of PCBs is not expected to result in substantial risk. Fish consumption remains the main exposure pathway for PCBs. In order for PCBs to evaporate in high enough levels to present a risk to human health or the environment, highly contaminated sediments would need to be exposed to the air for long durations. No such condition exists or will exist at the Site.

During the design process, EPA will review any relevant new information regarding PCB volatilization to determine if credible new data exist to indicate that there is an existing human health risk from volatilization of PCBs sufficient to revisit the remediation footprint. The CERCLA process also provides safeguards to ensure that remedies remain protective at sites where waste is left in place, in the form of five-year reviews once construction begins. Those reviews can include assessment of significant new data regarding protectiveness of the remedy.

In response to the comments on human health risks of PCBs, particularly risks to infants from breastmilk, EPA acknowledges the noted studies on such health effects and evaluated risks to infants whose mothers ate resident fish from Portland Harbor in the BHHRA. The BHHRA determined that exposure to bioaccumulative contaminants (PCBs, dioxins/furans, and organochlorine pesticides, primarily DDx compounds) via consumption of resident fish poses the greatest potential for human exposure to in-water contamination. The greatest non-cancer hazard estimates are associated with bioaccumulation of PCBs through the food chain and exposure to infants via breastfeeding. Due to those conclusions, EPA has determined that cleanup of PCBs and other bioaccumulative toxics found at the Site require cleanup.

### 2.33.2 Include Transient Species in Risk Evaluation

#### Comment Summary

Two comments were received related to fish consumption. They cite underestimated risks due to a lack of inclusion of transient fish (such as salmon) and Fish Consumption Rates recently passed in Oregon and Washington.

The comments are:

- “Risk estimates for fish consumption do not include additional risk from consumption of transient fish, such as salmon, that could be a large proportion of the subsistence diet. This makes the risk estimate an underestimate of the true risk, as opposed to the statement by EPA and/or the Lower Willamette Group that the estimates of risk are upper bound estimates.”
- “EPA must also recognize the import of the new Fish Consumption Rates that have been passed in Oregon and Washington's water quality rules -- which are the nation's highest. This is a reflection of the needs of our fishing peoples, and a recognition that a century of industrial pollution has created serious harm in their communities which we must commit to removing. EPA's Portland Harbor clean-up MUST move with all deliberate speed toward the protection of marine life and fish-dependent communities who are at risk from the accumulation of toxic substances in species like the pacific lamprey -- both from immediate absorption, and from risks to the marine food chain if lamprey continue on their current path to extinction.”

#### EPA Response

EPA's remedy focuses on reducing the risks to consumers of resident fish. This is because the remedial investigation determined that resident fish such as smallmouth bass and carp contain higher levels of contamination than transient fish such as lamprey, salmon and sturgeon. In addition, due to the large home range of transient fish, it is not possible to quantify the contribution of contamination in Portland Harbor versus other sources. However, because EPA's remedy is designed to reduce tissue concentrations of resident fish to protective levels, the potential for exposure to transient fish will also be reduced.

Regarding fish consumption rates, EPA's risk assessment used a range of exposure scenarios including a non-tribal subsistence fisher at a fish consumption rate of 142 grams per day consuming only resident fish only, and a tribal fish consumption rate of 175 grams per day consuming a mixed resident and transient fish diet. In addition, ambient water quality standards established by the State of Oregon that are based on a fish consumption rate of 175 grams per day are considered applicable or relevant and ARARs for the Site. Under CERCLA, the remedy is required to meet ARARs such as the state water quality standards.

EPA's tribal fish consumption scenario is based on a mixed diet that includes both resident and transient fish which was done at the request of the tribes and consistent with the Columbia River Inter-Tribal Fish Commission study on tribal fish consumption. Thus the risks associated with consumption of transient fish is considered in the tribal risk assessment and does not result in an under estimation of risk. Additional information on transient fish species is provided in the discussion of tribal comments in Section 3 of this responsiveness summary.

## 2.34 Ecological Risk

### 2.34.1 Address Inconsistencies in Benthic Risk

#### Comment Summary

Several comments were received from LWG and other businesses questioning the benthic risk evaluation presented in the 2016 feasibility study report and proposed plan. The commenters noted that the identification of benthic risk areas in the feasibility study report was inconsistent with the EPA approved BERA (Windward 2013) which relied on a multiple lines of evidence evaluation of benthic risk using the comprehensive benthic risk area approach.

The comments are summarized as follows:

- Several commenters stated that there is no scientific basis for EPA's abandonment of the comprehensive benthic risk area and that the new approach in the feasibility study is not more accurate, not more consistent with the BERA, and not more predictive of benthic risk or the effectiveness of the alternatives. Commenters further stated that EPA's 2016 analysis for analyzing benthic risk is a significant and technically indefensible departure from the well vetted comprehensive benthic risk area. They state that EPA abruptly and without explanation abandoned the approach and EPA's preferred alternative now identifies areas for cleanup based on a single point exceedance of a PRG.
- One commenter stated that EPA supported the comprehensive benthic risk area approach for many years before abruptly abandoning it in the final stages of preparation of the 2015 draft feasibility study report. The commenter stated that on April 4, 2014, EPA provided final direction to LWG on mapping the comprehensive benthic risk areas for the 2012 LWG draft feasibility study and on February 27, 2015, EPA requested that LWG submit revised text and maps incorporating its April 4, 2014 direction.
- Commenters noted that EPA simply mapped benthic PRG exceedances and used a 10 times exceedance factor to identify benthic risk areas, then arbitrarily determined that if active remediation addressed 50 percent of the benthic risk area, protectiveness would be achieved. Several commenters stated that the interim targets are arbitrary and that determination that a remedy is protective if it achieves 50 percent of the interim target is a second arbitrary step not tied to any quantitative assessment.

- Many commenters stated that EPA's assessment of benthic risk is arbitrary and capricious because it is not based on available toxicity testing data in sediments, and no credible scientific basis supports EPA's delineation of benthic risk areas and the extent of remediation necessary to reduce risks in these areas. If there is not risk to benthic organisms based on actual toxicity data, there is no need for remediation in those areas.
- It was noted that the large benthic risk areas mapped in the 2016 feasibility study report and proposed plan extend into areas shown to lack toxicity based on laboratory toxicity tests and other BERA lines of evidence. Thus, the benthic toxicity that EPA's proposed plan assumes exists in these area in fact does not exist and that the overall result of this haphazard approach is to require large amounts of active remediation on the basis of RAO 5 while failing to even address all of EPA/LWG comprehensive benthic risk areas previously agreed to.
- Commenters stated that the comprehensive benthic risk area approach identified approximately 61 acres for remediation based on benthic risk. It was noted that the benthic risk areas identified in the feasibility study report represented 1,289 acres or approximately 20 times the comprehensive benthic risk area. It was further noted that despite this, EPA's preferred alternative fails to capture 16 percent of the locations mapped through the EPA/LWG approach as presenting clear evidence of benthic toxicity.
- Several commenters suggested that the ROD should allow for modification of remedial footprints established based on benthic toxicity during remedial design and that EPA's ROD should state clearly that parties may use site-specific toxicity testing to verify model outcomes and design the final remedial action. It was suggested that relevant information, including data collected in pre-remedial design or remedial design work led by actual benthic toxicity testing, should be evaluated consistent with the EPA-approved BERA and refine benthic risk areas for active remediation, not by using single point exceedances.
- One commenter noted that the evaluation of PAHs at Terminal 4 should be based on direct toxicity measurements rather than EPA's 2016 benthic risk analysis because PAH contamination associated with pencil pitch present in Terminal 4 sediments is less bioavailable than other forms of PAH contamination.
- It was noted that the benthic risk evaluation utilized in the 2016 feasibility study and proposed plan is flawed and inconsistent with the BERA. As a result, RAO 5 PRGs are not risk-based and therefore are inconsistent with NCP and application of the PRGs leads to arbitrary and capricious remedial determinations.
- Another commenter stated that EPA failed to account for the fact that site benthic risk has improved since the data used in the BERA were obtained and that the Alternative B RALs as specified in the proposed plan would result in acceptable benthic risk reduction for the entire Site.
- Two commenters stated that EPA makes numerous errors, or did not properly document individual benthic PRGs for RAO 5 for a number of chemicals including PCBs, TPH, DDx, DDE, DDT and cadmium.

## EPA Response

The commenters do not provide a clear or specific basis for why the comprehensive benthic risk area approach should be used instead of the BERA (Windward 2013) and the 2016 feasibility study report (USEPA 2016b) alternatives evaluation approach. To clarify, the comprehensive benthic risk area approach was not utilized in the final BERA presented as Attachment G of the remedial investigation report (USEPA 2016a). Rather, benthic risks were evaluated using multiple lines of evidence as presented in Section 6 of the BERA report (Windward 2013). The evaluation of benthic risk in the BERA considered multiple lines of evidence including sediment toxicity testing, the floating percentile and logistic regression predictive models, generic sediment quality guidelines, tissue residue assessment and comparison of surface water and transition zone water to water based toxicity reference values.

In the BERA, impairments in survival and growth (expressed as biomass) were directly measured at nearly 300 locations, using site-specific sediment toxicity tests with two benthic invertebrate species. The co-occurring sediment contaminant concentrations where toxicity was observed were used in the development of two site-specific predictive models of sediment toxicity, the floating percentile model and the logistic regression model. Contaminant concentrations predicted to be toxic from these two models were used to evaluate benthic risk on a point-by-point basis in the final BERA. The two models are also the source of many of the RAO 5 sediment PRGs (and the resulting cleanup levels in the ROD) for ecological risk. Other PRGs are based on generic sediment quality guidelines and tissue residue line of evidence. Overall, the PRGs for RAO 5 were based on the sediment quality values derived in the BERA and incorporate the empirical toxicity results conducted at the Site. Thus, the PRGs (and the resulting cleanup levels in the ROD) are consistent with the conclusion of the BERA.

The comprehensive benthic risk area developed by EPA is shown in Figure 4.1-1 of the 2016 feasibility study and was developed using interpolation of surface sediment concentrations exceeding the RAO 5 PRGs. Mapping of benthic risk areas based on a point-by-point PRG exceedance is justified due to the limited mobility of many of the benthic species (for example, oligochaete worms and the Asiatic clam, *Corbicula fluminea*) that comprise the benthic community at the Site. This means that some benthic species may be exposed to contaminant concentrations exceeding risk-based thresholds for the majority of their lifetime. Additionally, benthic species are likely exposed to sediment contaminant concentrations for a sufficiently long exposure duration that results in contaminant bioaccumulation to concentrations (the RAO 6 PRGs) posing risks to aquatic-dependent wildlife species that prey on benthic species. Since EPA's RALs for requiring active remediation are not based on benthic risk PRGs, they will be monitored post construction until such time as they are achieved.

Under EPA's *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments – Interim Final (June 1997)* (USEPA 1997) adverse effects on populations can be inferred from measures related to impaired survival, reproduction and/or growth. A subsequent EPA Policy memorandum (*Issuance of Final Guidance: Ecological Risk Assessment and Risk Management Principles for Superfund Sites, OSWER Directive 9285.7-28 P, October 7, 1999*) (USEPA 1999) states that ecological risk assessments are intended to protect local populations and communities of biota. This approach was extensively used to evaluate ecological risks at Portland Harbor. The conclusions of the BERA indicate which contaminants are posing unacceptable risk based on those lines-of-evidence (site-specific toxicity tests, bioaccumulation models, and species diversity studies; BERA Table 3-1). These are all based on empirical site data and these lines-of-evidence cannot be used to determine effects to the benthic population through means other than empirical testing post -construction.

As noted above, EPA adopted the site-specific sediment quality values from the BERA for the RAO 5 PRGs. EPA made the risk management decision to not address all unacceptable benthic risk through dredging and capping and allow for some unacceptable benthic risk to be addressed through MNR. However, in conducting the evaluation of alternatives, it is necessary to discuss the overall protectiveness. EPA made a risk management decision to evaluate overall protectiveness for RAO 5 in the 2016 feasibility study (Section 4.1.3, RAO 5) as:

*“The protection of benthic species to contaminated sediment is evaluated using the benthic risk area defined by an order of magnitude greater than the RAO 5 PRGs. The post-construction interim target for RAO 5 was established at 50 percent reduction in the area posing unacceptable benthic risk. This is acceptable because protection of the benthic community is based on a population rather than individual effects, and is considered a target to which the benthic population as a whole can be stressed and still recover, in conjunction with the uncertainty associated with the predictive models used to develop these PRGs.”*

Thus, the 2016 feasibility study used the same metric as all other RAOs in establishing an interim goal that was an order of magnitude greater than the PRGs. EPA made this risk management decision based on the conservativeness of the sediment quality values used in the models (see BERA Section 6.2.5). EPA made further risk management decisions that the entire area above the RAO 5 PRGs did not need to be addressed through capping and dredging and made an assumption that if 50 percent was addressed through active remediation, the other 50 percent would be addressed through MNR. Since benthic effects from contaminated sediment are due to reproduction and growth, not just survival, this approach would also ensure that the entire population was not diminished through active remediation (capping and dredging is assumed to kill benthic organisms where it occurs).

The sediment PRGs developed for RAO 5 (reduce risk to benthic organisms from ingestion of and direct contact with COCs in sediment to acceptable exposure levels) considered the tissue residue line of evidence, and the two site-specific predictive models of toxicity to benthic species. PRGs for the tissue residue line of evidence were estimated using benthic tissue residue values and site-specific biota sediment accumulation factors. Site specific predictive models included the Logistic Regression Model and the Floating Percentile. The details of these approaches are described in Section 6 of the BERA. The lowest of these values for a given contaminant was selected as the RAO 5 PRG. COCs for which a site-specific value could not be developed (lindane and zinc) relied on sediment quality guidelines (McDonald 2000) and are used as the PRG. Water based exposures are addressed through RAOs 7 and 8. As described in Section 6 of the BERA, the evaluation of benthic risks due to exposure to contaminated sediment relied on sediment toxicity testing, site-specific predictive models, generic sediment quality guidelines and tissue residue concentrations. Thus, the PRGs presented in the final feasibility study consider all lines of evidence (including toxicity through the use of the predictive models) considered in the evaluation of benthic invertebrate risk in the BERA rather than a single predictive model.

As presented in Figure 2.2-2 of the final feasibility study report, areas of unacceptable benthic risk represent 1,289 acres of the Site. However, interim targets for risks and hazard indices were established to evaluate the potential for achievement of PRGs in a reasonable time frame. For RAO 5, the interim target is based on multiplying the RAO 5 PRG by an order of magnitude to account for further reductions due to MNR. In addition, the post-construction interim target for RAO 5 was established at a 50 percent reduction in the area posing unacceptable benthic risk. As explained above, this is because risks to the benthic community are based on a population level rather than individual level effect and 50 percent

considered a target to which the benthic population as a whole can be lost and still recover. As shown in Table 4.2-7 and Figure 4.2-25a of Appendix IV of the ROD, EPA's preferred alternative, Alternative F Modified addresses the majority of the Site (72 percent) that exceeds the RAO 5 PRGs by more than an order of magnitude (10x). Thus, the 2016 feasibility study report used the same metric as all other RAOs in establishing an interim goal that was an order of magnitude greater than the PRGs.

Regarding the basis for the RAO PRGs, the process to develop the PRGs is summarized in Appendix B and Table B4-1 of the feasibility study report. Table B4-1 presents the PRGs for each line of evidence considered, the source of the PRG and the PRGs used in the feasibility study report. The direct contact PRGs presented in Table B4-1 are based on the sediment quality values presented in Section 6 of the BERA (Tables 6-10, 6-12 and 6-18). As described in Section B4.1 of Appendix B, Logistic Regression Model sediment quality values based on organic content or percent fines normalization were converted to bulk sediment concentrations assuming the site-wide average sediment organic carbon of 1.71 percent and 53.38 percent fines from the BERA database. The approach for developing PRGs based on the ingestion of prey is presented in Section B4.2 of Appendix B of the feasibility study report.

As described in the ROD, additional data will be collected during remedial design for selection and design of the remedial technology to be implemented in specific locations. This may include toxicity testing, as applicable to refine delineation of benthic risk areas in areas that are not driven by risk via another RAO. Toxicity testing conducted for the Portland Harbor BERA 10-day survival and biomass test using the midge *Chironomus dilutus* and the 28-day survival and biomass test using the amphipod *Hyalella azteca*. These tests are included in the 2016 SEF for the Pacific Northwest (RSET 2016). Site specific sediment toxicity testing will include the two aforementioned test species. Interpretation of the result will be based on the acceptance criteria (hit definitions) outlined in the SEF.

## 2.35 Environmental Justice

### 2.35.1 Eliminate the CDF

#### Comment Summary

Four commenters wrote expressing concerns regarding environmental justice issues related to having a disposal facility in North Portland at Terminal 4. They were concerned that North Portland was unfairly being singled out as a dumping ground and a location for industry because it is a poorer, disadvantaged community.

Comments include:

- "Where are you going to carry out your final disposal method? Please don't dump it in North Portland. I understand that the esteemed city council has drawn a red line around North Portland having determined that anything or anybody that nobody wants in their back yard can just be stuck there."
- "I moved to St. Johns with my daughter and aging parents to start an educational toy and book store. This beautiful neighborhood is not the place I want to see toxic muck dumped. How is this not a bigoted decision? Drop the garbage in Portland's poor part of town. They won't pay attention or put up a fuss. Well, the area is changing, and we ARE paying attention. Please relocate your toxic dump site to a place that children and dogs do not play."

- “North Portland residents have had more polluting industries than many areas of Portland. The contamination from the Superfund cleanup should not be stored or left in the river. Remove the contamination.”
- “The needs of communities most affected by the contamination in the Portland Harbor over the decades should be carefully considered. While the League cannot speak for them, we understand that cleaning up the Portland Harbor so that they and others can consume resident fish without concern of harming their health is of utmost importance. Furthermore, because these communities are neighbors to a number of environmental hazards due to industrial activity, siting a toxic waste dump (Confined Disposal Facility) in their vicinity would add insult to injury. EPA needs to pay particular attention to these communities when adopting and implementing the cleanup plan.”

### **EPA Response**

The final selected remedy will not employ a CDF at Terminal 4. The location of the CDF at Terminal 4, as described in the proposed plan (USEPA 2016c) was evaluated because the Port of Portland was a willing sponsor of the facility and the CDF location was within the Portland Harbor Site so that dredged material would not need to be transported a long distance. EPA recognizes that low-income and/or minority populations reside in areas adjacent to the proposed CDF location, as well as the Portland Harbor Site as a whole, and therefore environmental justice concerns were considered. EPA assessed the use of a CDF as a way to reduce impacts to surrounding communities that result from the transport of dredged material off site. However, given the significant community concerns received on the use of an on-site CDF, and the recent withdrawal of support by the Port of Portland for the Terminal 4 CDF, an on-site disposal in a CDF is no longer a component of the final cleanup decision (Section 2.14.1 of this responsiveness summary).

## **2.35.2 Improve Insufficient Outreach to Environmental Justice Communities**

### **Comment Summary**

A total of 1,354 comments were received regarding what was perceived to be EPA’s lack of attention to environmental justice issues. The following two quotes were received as form emails or postcards and represent over 98 percent of the comments:

- “EPA should do a much better job of addressing environmental justice issues, including reviewing and correcting significant deficiencies in its public engagement strategies for future phases of the Superfund process and delineating strategies for ensuring the jobs, economic benefits and other benefits associated with the Superfund process to the local community and particularly to underserved communities that have been impacted by contamination in Portland Harbor.”
- “This site presents characteristics of an Environmental Justice community, yet EPA has not addressed this issue. EPA needs to assess the EJ aspects of this site and take appropriate action to enhance protective and remedial measures.”

The remaining comments echoed this theme. Several comments also referred to the lack of an environmental justice analysis. Representative comments are:

- EPA is failing environmental justice issues, particularly to historically (criminally) underserved communities. People in Portland notice and are calling you out. Take a stand, we are begging you.

- As detailed more explicitly in the comments we submitted with the Portland Harbor Community Coalition, the Portland Harbor Site must be assessed through the lens of Environmental Justice. We believe EPA has not adequately considered the EJ aspects of this site, so it must now take the appropriate action to enhance protective and remedial measures for the impacted communities.
- The proposed plan is a huge disappointment to me personally, and is especially damaging to the communities most impacted by the contamination, such as Native Americans, African Americans, Latinos, East Asian, Eastern European, houseless, and other immigrant / refugee groups. These communities face the harshest costs of a polluted river, such as displacement, exposure to toxins, and violations of treaty rights. I urge EPA and Oregon legislators to restore the Willamette today for all people and generations.
- I also have concerns that the analysis, and the proposed plan, did NOT deal adequately with social justice issues -- and that, once again, people of color and lower-income residents will be the ones who continue to be impacted the most by leaving so much pollution in the river.
- I was surprised that I could not find an analysis of the environmental justice dimensions of the existing situation or the impacts of the alternatives. I thought this was a required element of an EIS. It seems reasonable to assume that more complete cleanup of contaminants would improve their lives. Greater public access should be a goal of the entire process, and the public should have enough information about the process to know when to engage in the public decision processes at the state or local level to protect environmental justice interests. Agreements between impacted communities, polluters and government must be made to insure equity provisions are implemented during and following cleanup.

### EPA Response

EPA takes environmental justice seriously and has worked to understand environmental justice concerns in the Portland Harbor study area and also spent significant time and resources on outreach to communities with environmental justice concerns. In an effort to integrate environmental justice and community engagement efforts, the proposed plan (USEPA 2016c) provided a short summary of the community groups that EPA worked with in addressing environmental justice issues related to the Portland Harbor study area. While the proposed plan listed some of the names of these organizations, EPA could have done a better job in highlighting the tremendous effort and work that occurred between community based organizations and EPA in order to address environmental justice concerns at the Portland Harbor Superfund Site. However, EPA did use existing methodologies that support environmental justice considerations and guiding principles for environmental justice analyses at the Portland Harbor Superfund Site. For example, the use of online tools is one of the methods for supporting environmental justice analyses. Web-based geographic information system mapping tools assisted the region in defining, delineating, and characterizing communities with environmental justice concerns. Region 10, in its effort to understand initial environmental justice issues for the Portland Harbor Superfund Site used EJ View, in screening the community demographics and subsequently in EJ Screen and the Community-Focused Exposure and Risk Screening Tool (C-FERST).

Detailed information is provided below about environmental justice work that was conducted at the Site.

- **Use of EPA's Environmental Justice Screen (EJSCREEN) tool at the Portland Harbor Superfund Site:** EJSCREEN is an environmental justice mapping and screening tool that provides EPA with a nationally consistent dataset and approach for combining environmental and

demographic indicators. An EJSCREEN analysis of the Portland Harbor Superfund Site was conducted which resulted in a demographic analysis of the study area and also the creation of a map that displayed this information. Specifically, the map displayed the areas of contamination at the Portland Harbor Superfund Site and marked locations where the population was under age 18, below the poverty line, spoke English less than well and had less than a high school diploma. Additionally, data reflecting the percentage of the population that was minority and the percentage of the population that was white in a 0.5-mile radius and 2.5-mile radius of the Site was displayed as well as per capita income and household income less than \$15,000. This map was presented at community information sessions and meetings.

- **Use of EPA’s C-FERST:** C-FERST links to and builds upon other community-focused guidance and tools to help identify human exposures and potential risks for a community and to help identify issues for further assessment and actions that are available to improve public health. EPA Region 10’s environmental justice coordinator had multiple sessions with members of the Portland Harbor Community Coalition members to discuss and address environmental justice concerns and train coalition members to use a pilot version of the C-FERST tool to conduct analyses over the course of a year. Also, just this year, EPA has officially launched C-FERST and looks forward to continuing to work with coalition members and other interested groups to utilize this tool for environmental justice work.
- Application of EPA’s six guiding principles for environmental justice analyses to determine any disproportionately high and adverse human health or environmental effects to low-income, minority, and tribal populations. These principles include:
  1. Consider the composition of the affected area to determine whether low-income, minority or tribal populations are present and whether there may be disproportionately high and adverse human health or environmental effects on these populations. This principle applies to Portland Harbor as follows:
    - EPA identified diverse neighborhoods, organizations, schools, businesses, religious institutions, the University of Portland, and government offices that are located within an approximate 2.5-mile radius of the Portland Harbor Superfund study area. Approximately twenty-four percent of people living within the area of the Portland Harbor Superfund Site are minorities; fifteen percent of homes are English as a second language households. Other communities, not necessarily living near the river, also recreate in the Portland Harbor area. These include Spanish-speaking, Vietnamese, Hmong, Chinese, Ethiopian, Somali, and Russian/Slavic communities.
  2. Consider relevant public health and industry data concerning the potential for multiple exposures or cumulative exposure to human health or environmental hazards in the affected population, as well as historical patterns of exposure to environmental hazards. This principle applies to Portland Harbor as follows:
    - The Baseline Human Health Risk Assessment considered and focused on vulnerable populations that included children, pregnant women, women who are breast feeding, tribal fishers, transient populations, including the houseless populations, and people who work in and around the Portland harbor study area. The full

Baseline Human Health Risk Assessment is available on EPA's Portland Harbor website at the following link: <http://semspub.epa.gov/src/document/10/687176>

3. Recognize the interrelated cultural, social, occupational, historical, or economic factors that may amplify the natural and physical environmental effects of the proposed action. This principle applies to Portland Harbor as follows:
  - Attending quarterly briefings with the Oregon Environmental Justice Task Force meeting to share information about the Site, public involvement opportunities and to hear ideas on how to better involve communities with environmental justice concerns. The Oregon Environmental Justice Task Force was created by the Oregon legislature to help protect Oregonians from disproportionate environmental impacts on minority and low-income populations.
  - Holding four public meetings in June and July 2016 during the public comment period for the proposed plan that were well advertised including posting translated notices in Spanish, Vietnamese and Russian publications. Language interpretation was available at all meetings upon request and was utilized at the June 24<sup>th</sup> meeting (Spanish, Russian, Vietnamese, and Chinese) and at the July 20<sup>th</sup> meeting in the evening (Spanish, Russian and Arabic).
4. Develop effective public participation strategies. This principle applies to Portland Harbor as follows:
  - Using novel outreach techniques to engage communities, such as workshops, ethnic festivals, children's water festivals, presentations to Native American Youth and Adults, Portland City and Earth Care summits, boat tours for stakeholders, Superfund 101 training and radio broadcasts. In addition, EPA developed and distributed multilingual materials and provided translation services upon request during information sessions.
  - Partnering with the Portland Harbor Community Coalition since 2012 to hear and address environmental justice concerns and the need for meaningful involvement at the Site. The coalition is comprised of individual community members, community of color organizations, conservation organizations, environmental justice organizations, higher educational institutions and tribes. EPA recognized that the coalition was able to conduct outreach to communities with environmental justice concerns and understands the needs of these communities. As a result, EPA wanted to connect and collaborate with coalition members. For example, in March of 2015 EPA conducted a Portland Harbor and Superfund 101 training entirely in Spanish for the Portland Harbor Community Coalition and Verde.
  - Engaging with many different groups that represent or are concerned about communities with environmental justice concerns such as Communities of Color, the Native American Youth Association, Latino Network, Right 2 Dream Too, Right 2 Survive, Willamette Riverkeeper, the Slavic Immigrant Association, Ecumenical Ministries of Oregon, the Coalition of Black Men, Oregon Tradeswomen, League of Women Voters, Verde, Portland Harbor Community Coalition, Sierra Club Portland, Occupy St. Johns, Audubon Society, Asian Pacific American Network of Oregon,

Vietnamese Community of Oregon, Portland neighborhood associations and schools. EPA has also used public information sessions, fact sheets, websites, one-on-one discussions, and participation in community events as ways to share information with the broader community. A detailed list of specific community involvement activities is available in EPA's current Portland Harbor Community Involvement Plan.

- Designing and disseminating the Portland Harbor Brain Bender Activity Book for students that has educational activities with math, geography, biology and word finds to help 6<sup>th</sup> – 8<sup>th</sup> grade students learn more about the Portland Harbor Superfund Site.
  - Producing and disseminating quality information such as community information cards that outlined key information about the Portland Harbor Superfund Site in English, Spanish, Vietnamese, Russian and Chinese.
  - Attending and presenting at public forums and meetings and also organizing multiple community information sessions in many different locations around the Portland area during January, February and March of 2016 in advance of the release of the proposed plan. At the EPA community information session at the Immigrant and Refugee Community Organization, EPA provided Spanish and Russian interpretation.
5. Assure meaningful community representation in the process, beginning at the earliest possible time. This principle applies to Portland Harbor as follows:
- Holding focus groups and one on one meetings with representatives from the Portland Urban League and Coalition of Black Men, Groundwork Portland, Verde, and many organizations not represented by the Community Advisory Group. As a result, members of these community groups added input, participated in trainings, and advised EPA on appropriate ethnic venues for advertising meetings and how their members could best become informed about the Portland Harbor concerns. This allowed for EPA to actively and intentionally utilize the Chinese, Vietnamese, Hispanic and Russian news media, papers, newsletters, and/or diverse community announcements.
  - Providing interpretation services at the proposed plan public meetings upon request and providing materials that were translated into Spanish, Russian, Vietnamese, and Chinese. Meetings were provided at different times of the day and evening and in multiple locations.
  - Providing financial support to the Willamette Riverkeeper since 2001 via a technical assistance grant. The Willamette Riverkeeper has used this grant to give support to the CAG which provides a public forum for community members to learn about the Site and share community needs and concerns, including environmental justice concerns. EPA intends to continue providing this financial support as long as there are community organizations that are able to maintain the technical assistance grant.

- Collaborating with DEQ and the Oregon Health Authority to reach out to underrepresented communities that are not involved with the CAG to hear their voices and to seek resources outside the scope of the Superfund program that may support community objectives.
  - Providing environmental justice training to the Community Advisory Group by the environmental justice community liaison along with presentations and training on job readiness to the Oregon Task Force, Oregon Tradeswomen and the Portland Harbor Community Coalition. Superfund 101 sessions were provided on a Saturday for community members where representatives from Right 2 Survive and the houseless community attended and provided input.
  - Providing and disseminating quality information during the release of the proposed plan, specifically a community fact sheet as well as an acronym, glossary, contaminant summary and a handout detailing how to give written or oral comments that were all translated into Spanish, Vietnamese, Chinese and Russian. Additionally, EPA posted translated notices about the release of the proposed plan in Spanish, Vietnamese and Russian publications.
6. Seek tribal representation in the process. This principle applies to Portland Harbor as follows:
- There is significant information regarding tribal engagement in the proposed plan and the community involvement plan listed on the Portland Harbor website. Additionally, please find more information about tribal engagement in Section 3 (Tribal Comments and Responses) of this responsiveness summary.

In summary, EPA recognizes that many commenters felt that environmental justice concerns need to be given more attention as EPA moves forward with remedial design and remedial action at the Portland Harbor Superfund Site. Transparency is a key value of EPA and as we move forward, we seek to continue to demonstrate our commitment to making a visible difference in the communities we serve. EPA looks forward to continuing to collaborate and work with the groups outlined above and also form new relationships with others who can help us conduct better outreach to communities with environmental justice concerns. Lastly, the upcoming required revision to the Portland Harbor Community Involvement Plan will provide another opportunity to discuss and explore these ideas and issues more deeply.

Please also see the following responses in this responsiveness summary to other comments that address these topics:

- EPA's post-ROD outreach plans (Section 2.36.2)
- Financial support to communities with environmental justice concerns (Section 2.36.5)
- Outreach associated with the proposed plan (Section 2.36.1)

### 2.35.3 Consider Food-Based Environmental Justice Issues

#### Comment Summary

Ten personal comments were received from the public, including the *Oregon Physicians for Social Responsibility*, that related specifically to environmental justice because of the lack of fish that were safe for the Native peoples, people of color, and low-income groups.

Representative comments include:

- Like many middle-class Oregonians, there is no way I would gamble on eating the fish from the Willamette. Nothing in the current plan would dissuade me from that. However, lots of people don't have the choice that I do. The current plan ensures that the impact would continue to fall disproportionately on the poorer communities that rely on the Willamette.
- In the time I spend on the river, I also disproportionately see people of color and low income folks fishing in the Superfund site. They are the ones whose health is most impacted, and social justice demands that we protect everyone who uses the river, especially those who depend on it to supplement their diets.
- How environmental justice issues - specifically how people of color, Native Americans, low-income households and others disproportionately affected by bio-accumulative contaminants and by continued fish consumption advisories due to their reliance on fish from the Willamette River for cultural and nutritional purposes - will be addressed.”
- Failure to clean the river to a level at which fish are safe for human consumption renders the cleanup a classist and racist action: The populations that most heavily use the river are people who are homeless and Native American communities, as well as some of the Black communities that have already are subject to the most polluted areas of the city.
- The Preferred Alternative I is chosen because it is relatively less expensive and will require only seven years of construction, rather than 60 years to conduct the cleanup. And yet still it will not permit fish from the harbor to be consumed by subsistence fishers. This is a serious violation of environmental justice values and one that EPA should take seriously
- We also call on EPA to require the most effective cleanup technologies available, regardless of cost, to fully clean up the Portland Harbor in a way that does not harm Pacific lamprey eel that are embedded in the sediment as long as 7 years. Scientific evidence suggests that Pacific lamprey, which have been in existence for over 500 million years, are one of the foundational species of the Columbia basin, and that the potential loss of Pacific lamprey in the Columbia basin threatens the basin's ecological integrity. Lamprey is also an incredibly important cultural food, and provide a very important source of nutrition, as they are exceptionally rich in fats (much more so than salmon). Due to the loss of lamprey throughout the Columbia Basin, many young tribal members have never even seen a lamprey, and are losing historically important stories and ceremonies that are associated with them.
- EPA must recognize that environmental restoration is not a discretionary function -- it a fundamental issue of justice at the heart of EPA's mission. Environmental restoration is necessary for the restoration of the traditional cultures of the Pacific Northwest, who currently suffer from severe health problems as a result of the disruption of their traditional food sources -- including salmon, lamprey, and wapato in the Portland Harbor.”
- A human health risk assessment was performed for the Site which showed that health risks from exposure to contaminants in the river are highest for populations consuming large amounts of resident fish from the Site. As a result, it makes sense that areas used more frequently by the most

impacted or underserved and underrepresented populations should have a more aggressive schedule for cleanup.

### **EPA Response**

Executive Order 12898 directs federal agencies, including EPA, to identify and address environmental justice concerns for minority populations and low income populations to the maximum extent feasible. The primary purpose of CERCLA is to remediate releases of hazardous substances to the environment that are presenting unacceptable risk to human health and the environment. As a result of public comments like the ones outlined above regarding environmental justice and fish consumption, EPA has chosen a more aggressive cleanup option on the releases of hazardous substances to the Site that will allow for additional fish consumption after construction of the remedy is complete. However, current background contaminant levels coming into the Site will still make it difficult for those most at risk (such as Native Americans, subsistence fishers and women who are breastfeeding) to consume an unlimited quantity of fish. Fish advisories due to contamination at the Site would be modified based on the results of long-term monitoring of contaminants in fish tissue and fish tissue surrogates (such as passive monitoring, where necessary). Watershed-wide planning efforts by the Oregon DEQ, EPA and other groups may eventually reduce background contaminant concentrations and further increase fish consumption, although the Oregon Health Authority may still impose a fish advisory based on broader watershed risks.

In the meantime, EPA does support some of the specific environmental justice recommendations for fish consumption that were received during the public comment process such as prioritizing areas for cleanup that have high public use and increasing riparian-area signage for fish advisories. EPA already has engaged communities with environmental justice concerns on fish advisories and will apply this to future fish advisory work. In 2012, EPA started a revision project for the Portland Harbor fish advisories and discussed changes to the signs with the CAG, five neighborhood associations and representatives from the Slavic, Tribal, Latino and Vietnamese communities. From these discussions, EPA acquired valuable feedback to improve the fish advisory signs but also learned that we should better utilize non-profit organizations representing the various communities to communicate information, attend community association festivals, go to ethnic celebrations and submit articles to community newsletters. As a result of this previous fish advisory revision effort, EPA has already formed relationships with other non-profit groups and has attended additional events such as the Slavic Celebration in June. In the future, EPA intends to continue applying these suggestions to upcoming work regarding fish advisories and to facilitate participation by communities with environmental justice concerns.

Please also see the following responses in this responsiveness summary to other comments that address these topics:

- EPA's post-ROD outreach plans (Section 2.36.2)
- ICs (Section 2.28.1)

## **2.35.4 Consider Specific Suggestions for Additional Environmental Justice Support**

### **Comment Summary**

Fifteen comments were received that requested additional environmental justice actions. Requests include:

- Work with impacted communities to set aside land on or near the river for community use which could support community-controlled habitat restoration, housing, gardens, environmental education, and other community-identified and community-controlled activities.
- Establish Community Benefit Agreements with private-sector actors, ensuring equity-supporting redevelopment outcomes in the Harbor area, including expansion of living-wage jobs, affordable housing, and targeted outreach to bridge food and housing insecurities for disproportionately impacted groups relying on the Harbor area for basic needs (from the Health Impact Assessment submitted with the Portland Harbor Community Coalition comments titled *Portland Harbor Superfund Cleanup: Socio-Environmental Determinants of Health & Vulnerable Communities*).
- Formulate policy mechanisms to incubate equity-supporting economic activity in the Harbor, including microenterprises, light industry, and other entrepreneurship opportunities, toward growing the living-wage job market, with leadership by local residents and members of affected communities (from the Health Impact Assessment submitted with the Portland Harbor Community Coalition comments titled *Portland Harbor Superfund Cleanup: Socio-Environmental Determinants of Health & Vulnerable Communities*).
- Provide information to communities with environmental justice concerns in culturally appropriate ways, such as by ensuring that materials are translated and also disseminated by working with organizations who have established trust relationships with environmental justice groups affected by the contamination.
- Improve public engagement actions moving forward to address all environmental justice issues, engage more effectively with people living around the river and correct other deficiencies in EPA's public engagement strategies.
- Ensure that communities with environmental justice concerns have enough time to provide adequate comments on the cleanup plan for the Site.
- Change zoning to ensure that ceremonial land is given back to the tribes.

### **EPA Response**

As noted in previous responses, EPA believes that everyone deserves to be protected from pollution, not just those who can afford to live in the cleanest, safest communities. Executive Order 12898 directs federal agencies, including EPA, to identify and address environmental justice concerns for minority populations and low income populations to the maximum extent feasible.

EPA values the thoughtful comments and ideas that were submitted regarding additional environmental justice actions that should be conducted at the Site and we look forward to discussing the specific recommendations as remedial design and remedial action move forward. For example, EPA is committed to providing information to communities with environmental justice concerns in culturally appropriate ways and will continue to improve public engagement actions by working with the CAG, the Portland Harbor Community Coalition, Willamette Riverkeeper, Communities of Color, Native American Youth Association, Latino Network, Right 2 Dream Too, Right 2 Survive, the Slavic Immigrant Association, Ecumenical Ministries of Oregon, the Coalition of Black Men, the Oregon Environmental Justice Task Force, Oregon Tradeswomen, League of Women Voters, Verde, Sierra Club Portland, Occupy

St. Johns, Audubon Society, Asian Pacific American Network of Oregon, Vietnamese Community of Oregon, Portland neighborhood associations and schools, and any other interested parties.

Many of the concerned expressed by residents however appear to be outside the jurisdiction of EPA under CERCLA authority and EPA is limited in what it may do under existing authorities. We encourage the state to work with the appropriate organization to ensure that land use planning, housing, reuse of surrounding properties are considered in the overall planning for the area. Please also see the following responses to other comments in this responsiveness summary that address these topics:

- EPA's post-ROD outreach plans (Section 2.36.2)
- Hiring locally (Section 2.2.2)
- EJ and job creation (Section 2.35.6)
- EJ and financial support (Section 2.35.5)
- Relocation and housing issues for communities with EJ concerns (Section 2.35.7)

### 2.35.5 Address Issues of Financial Support Related to Environmental Justice

#### Comment Summary

Several comments were received that discussed providing financial support for communities with environmental justice concerns or funding independent community organizations to provide outreach to communities affected by the Site, particularly to communities of color and economically disadvantaged community members. Some of the specific suggestions offered by commenters about actions EPA could take to provide financial support to communities with environmental justice concerns include:

- Establish a fund to assist communities impacted by historic and ongoing contamination.
- Fund a study to determine where the most vulnerable communities are conducting activities along the river.
- Provide financial support to the CAG and the Portland Harbor Community Coalition to conduct effective community outreach to low income, Native American, minority and immigrant communities who are impacted by the cleanup actions.

#### EPA Response

EPA appreciates the comments and suggestions from commenters regarding financial support to better understand the needs of communities with environmental justice concerns and also to conduct quality outreach to the most vulnerable communities affected by the Site.

EPA looks forward to exploring these ideas with community members, to the extent that these are within the scope of the CERCLA response, as we move forward with remedial design and remedial action. Specifically, the upcoming required revision of the Community Involvement Plan for the Site may be an opportunity to have discussions about these ideas with the groups that have developed trusted relationships with the most vulnerable communities and also directly with community members who have environmental justice concerns.

EPA also is already considering ways to address some of the specific suggestions that were raised in the comments, such as a study to determine where the most vulnerable communities are conducting activities along the river. As part of the ICs implementation and assurance plan that lays out the approach for the development and implementation of ICs like fish advisories, EPA may conduct a survey of fisher communities, including Tribal, low-income, minority and immigrant communities, to verify the fish species being consumed, consumption rates, preparation and cooking practices (Section 2.28 of this responsiveness summary).

Additionally, EPA has provided financial support to the Willamette Riverkeeper since 2001 via a technical assistance grant. The Willamette Riverkeeper has used this technical assistance grant to give support to the CAG which provides a public forum for community members to learn about the Site and share community needs and concerns, including environmental justice concerns. EPA intends to continue providing this financial support as long as there are community organizations that are able to maintain the technical assistance grant and that the effort is within the scope of the CERCLA response.

Lastly, EPA also intends to maintain our strong partnerships with local, state and federal partners who also may be able to provide financial support to benefit communities with environmental justice concerns during the cleanup. For example, the Oregon Health Authority implemented a mini-grant application program from 2003-2009 which provided funding to community organizations to enhance outreach efforts to different ethnic groups and specific populations that catch and consume fish from the Site.

Please also see the following responses to other comments in this responsiveness summary that address these topics:

- EPA's post-ROD outreach plans (Section 2.36.2)
- Relocation and housing issues for communities with environmental justice concerns (Section 2.35.6)
- Hiring locally (Section 2.2.2)

### 2.35.6 Support Job Creation in Impacted Communities

#### Comment Summary

Seven commenters discussed the importance of ensuring that job training, jobs and other economic benefits are made available during cleanup, particularly to underserved communities, communities of color, low income people, women and other underrepresented groups impacted by the long-standing contamination. These comments came from the general public, as well as the Portland Harbor Community Coalition and the CAG.

Comments include:

- “Public engagement strategies used for the clean-up plan have not well-addressed environmental justice, specifically delineating strategies for ensuring the jobs, economic benefits and other benefits associated with the Superfund process are accessible to the local community and particularly to underserved communities that have been impacted by contamination in Portland Harbor. EPA is strongly urged to redress these deficiencies from this point on in the Superfund process.”

- “Heavily consider the environment justice issues by assuring jobs, and benefits to the underserved and local communities that have been impacted by the Superfund sites.”
- “EPA should do a much better job of addressing environmental justice issues by ensuring that the jobs and economic benefits of the cleanup are shared by the communities most impacted by the long-standing contamination.”
- “The plan should ensure the jobs, economic benefits and other opportunities associated with the cleanup accrue to underserved communities and communities of color that have been impacted by contamination and reduced access in Portland Harbor.”
- “I’ve worked on projects in a city outside of Portland, where the City went into contract with the large companies and required them to provide apprenticeships and internships that would focus on low income people, people of color, and women, and underrepresented people. I would also like to see the industries along the river -- and I was a member of the River Renaissance Committee years ago -- to require them to put money into a fund that would support this job training. I think these are very basic environmental justice principles where the benefits and the burdens of the action are equitable. So it’s important for the community people to benefit.”
- “Attract federal investment (e.g. Superfund Joint Training Initiative) and commit local resources (e.g. via Jobs with Justice) to job training and workforce development for mid-skill, living-wage jobs in the environmental and construction industries.”
- “Hiring for the cleanup should be kept local whenever possible, so that communities that have suffered the most exposure to contamination also benefit by the positive opportunities offered by the cleanup.”

### **EPA Response**

EPA supports all of the comments that were received regarding job training, jobs, local hiring and other economic benefits that should be made available for communities with environmental justice concerns during site cleanup. EPA often has some support available to address these suggestions such as the long-standing program called the Superfund Job Training Initiative. The initiative is a job readiness program that provides training and employment opportunities for people living in communities (including communities with environmental justice concerns) affected by Superfund sites. EPA’s goal is to help these communities develop job opportunities that remain long after a Superfund site has been cleaned up. EPA is already starting to explore how the initiative may be applied to the cleanup work at the Site.

Additionally, EPA is looking forward to continuing our existing partnerships with our community, Tribal, local, state and federal partners as well as forging new collaborative relationships to ensure that communities with environmental justice concerns reap economic benefits from the Site cleanup. EPA welcomes and encourages continued feedback from commenters and our partners on this important topic throughout the cleanup process.

Please also see the following responses to other comments in this responsiveness summary that address these topics:

- EPA’s post-ROD outreach plans (Section 2.36.2)
- Hiring locally (Section 2.2.2)

### 2.35.7 Address Environmental Justice in Regards to Relocation Housing

#### Comment Summary

Many comments were received by EPA regarding the houseless community living around the Site as well as displacement and general affordable housing for low and middle income residents. Some specific suggestions were provided by commenters, such as:

- Provide adequate notice before starting the cleanup in areas where houseless people are living.
- Provide funds for permanent, affordable housing for anyone displaced by the cleanup (whether housed or houseless).
- Institute robust anti-displacement provisions (as outlined in the City of Portland’s Comprehensive Plan) to ensure that low- and middle-income residents have access to permanently affordable housing in nearby neighborhoods.
- Encourage compensatory affordable housing with tax-incentives and other levers to increase affordable housing near the Site. Activate partnerships for community-guided development decision-making-targeting for involvement the vulnerable groups discussed herein (from the Health Impact Assessment submitted with the Portland Harbor Community Coalition comments titled *Portland Harbor Superfund Cleanup: Socio-Environmental Determinants of Health & Vulnerable Communities*).
- Link affordable housing preservation and development with market outcomes following the cleanup, for example, with directives to increase affordable housing in line with capitalization of the nearby housing/land market (i.e. an increase in mandated affordable housing would accompany a rise in average rental rate over time) - (from the Health Impact Assessment submitted with the Portland Harbor Community Coalition comments titled *Portland Harbor Superfund Cleanup: Socio-Environmental Determinants of Health & Vulnerable Communities*).
- Assure that working-class homeowners, including homeowners of color, capture the benefits of owning higher-value property, by offering community counseling on managing property taxes, refinancing, as well as code and permitting procedures for property improvements and rental-conversion.

#### EPA Response

EPA appreciates the many concerns and suggestions that were provided by commenters regarding the houseless community as well as displacement and general affordable housing for low and middle income residents. EPA does not anticipate that any resident will be displaced from their home as a result of the Site cleanup. If for some unanticipated reason, this does become necessary EPA has a well-established relocation guidance that has been successfully applied at many other sites throughout the country. For any relocation activities, EPA always provides early and frequent communication with the affected residents.

Regarding any displacement that would occur for members of the houseless community, EPA will make every effort to notify houseless community members in areas where cleanup activities are anticipated to occur as soon as possible before the start of any remedial action. Additionally, EPA intends to work closely with groups representing the houseless community such as Right 2 Dream Too, Right 2 Survive and any other interested organizations or individuals to facilitate communication of future cleanup

activities in areas that could affect houseless community members, and EPA will work with local authorities (such as the Oregon Department of Human Services) to connect houseless community members with any available resources.

EPA also looks forward to discussing other suggestions regarding housing and displacement that fall under the scope of CERCLA and the NCP as we move forward with remedial design. Other suggestions, such as community counseling for homeowners, may be better executed by other local, state or federal groups and EPA will help facilitate these connections wherever possible.

## 2.36 Public Participation

### 2.36.1 Address Public Outreach Related to the Proposed Plan or Earlier

#### Comment Summary

A total of 44 comments were received relating to public participation leading up to and including the proposed plan. All of the comments are personal comments. Roughly half of the comments requested an extension of the comment period, generally ranging from an additional 120 to 180 days, and several said that the timing of the comment period (summer) was poor. The remaining commenters stressed a need to better engage the public, either leading up to or during the comment period. One person thought that the format of the public meetings was flawed and that EPA should have agreed to additional meetings with a more traditional format, two people stated that it was wrong for people from Washington to be making decisions on the Site, one person was unhappy with email glitches at the beginning of the comment period, and a few people offered suggestions on improving future meetings.

Representative comments included:

- “I would like to see them seek more input from Portland residents. We have a right to voice our opinion on these issues, and certainly when it comes to our tax dollars.”
- “Improved understanding of the plan’s details and merits among concerned community members would improve cleanup implementation and acceptance. In this regard, we request that EPA and DEQ provide financial and technical resources to local organizations that are better equipped to directly engage local stakeholders about the merits and justification of the cleanup plan.”
- “There has not been a full buy-in from the community, including the CAG, the city and the state. CAG has dedicated years and extensive time to this issue and their opinions should be taken into consideration and heard during this process. To date, this has not been the case.”
- “It’s unfair that EPA is working with people in Seattle who have no connection to us. Instead, they should be working with people in Portland or in the state of Oregon. This plan will not affect anybody in Washington, unless that’s where the debris will be dumped. It will, however, affect us. EPA needs to start working with us instead.”
- It is deeply disappointing that after months of delay, EPA still does not appear to have adequate systems in place to maximize the efficacy of the limited comment period it has provided. It compounds an already challenging and controversial situation in which EPA has provided only 60 days for public comment, has subjected the public to serial delays, and has launched the comment period right at the start of summer break when many people are leaving town.

Three commenters thought that the public engagement process was allotted inappropriate time in order to meet the “political deadline” of a ROD by the end of 2016. These comments included:

- “Rushing through this process to meet a political deadline has the potential to short-change the long-term health of the Willamette, and the people who live near it, and use the river on a regular basis. The final structure of the ROD should not be influenced by verbal agreements between EPA leadership and politicians made years ago, or a desire to complete the ROD because of sheer political expediency.”
- “All of this has been informed by an unrealistic timeline for a ROD. Peter deFur, the technical Superfund Advisor retained by the Community Advisory Group, told the public that for EPA to reach a ROD by the end of the year, they would have to work in record time once the comment period ends, and more likely than not, the ROD has already been written. Taken together, all of this creates serious doubt that what we have witnessed over the last few months was a meaningful public process.”
- “We do not believe that EPA could reasonably consider and respond to the public comments that have been submitted and make appropriate modifications to the plan in the arbitrary timeframe that EPA has set for itself. EPA’s preoccupation with the December 31 deadline suggests that the public comment period was little more than a cursory exercise. We urge EPA to take the time necessary to give full consideration to the concerns that have been raised and make modifications to the plan as warranted. EPA should take whatever time is necessary to thoroughly read and respond to public comments and make appropriate changes to the feasibility study and Clean-up Plan, rather than attempting to stay on an unrealistic and politically driven timeline of reaching a final record of decision by the end of the year. Prioritizing the finalization of the ROD by the end of 2016 would relegate the public process to little more than a cursory checkbox.”

### **EPA Response**

EPA understands that some commenters felt that they were not sufficiently engaged in the process prior to the proposed plan (USEPA 2016c) being issued. EPA is always striving for improvement in this area and made a significant community outreach effort to get input for the proposed plan and to prepare people to participate in the public comment period. These efforts included producing and disseminating quality information such as community information cards, fact sheets and videos; maintaining current information on EPA’s Portland Harbor website; providing valuable information via the EPA Portland Harbor listserv; engaging with various organizations including groups representing people who live along the river; participating in one-on-one discussions; attending and presenting at public forums and meetings; and organizing multiple community information sessions during January, February and March of 2016 (Section 2.35.2 of this responsiveness summary).

EPA held tribal consultations during the public comment period with the Confederated Tribes of Grand Ronde, the Confederated Tribes and Bands of the Yakama Nation, Confederated Tribes of the Umatilla Indian Reservation and the Nez Perce Tribe. EPA consulted with the Confederated Tribes of Siletz Indians during the first round of consultations prior to issuing the proposed plan. In response to EPA’s invitation to consult during the public comment period, the Tribe told EPA that it did not wish to schedule another consultation. EPA also held four public meetings in June and July of 2016 (June 24, June 29, July 11, and July 20). These public meetings were well advertised via e-mail, posting on the Portland Harbor website, dissemination of media advisories, and directly posting EPA notices in *The Oregonian*, *The Skanner*, *The Asian Reporter*, *El Hispanic News* (translated into Spanish), *KAHOH*

(translated into Russian) and the Phương Đông Times (translated into Vietnamese). The meeting venues were widely spaced throughout the metro area (City of Portland Building, EXPO Center, University Place Conference Center, and the Ambridge Center). Two formal presentations of the plan were given at each meeting, followed by a question and answer period and an informal open house where the public could discuss the plan directly with EPA staff and ask questions one-on-one. At all public meetings, there were opportunities to provide both written and oral comments on the proposed plan for the record. Language interpreters were available in person at the June 24 meeting (Spanish, Russian, Vietnamese and Chinese) and at the July 20 meeting in the evening (Spanish, Russian and Arabic) and by telephone if needed at the June 29 and July 11 meetings. A community fact sheet as well as acronyms, glossary, contaminant summary, and a handout detailing how to give written or oral comments were available in English, Spanish, Vietnamese, Chinese and Russian at each public meeting. Based on feedback from the public, the format of the last meeting during public comment was updated based on real-time input from commenters. EPA appreciates the feedback from commenters on the presentations and will use these suggestions to improve future public meetings. Lastly, EPA intends to continue public outreach and participation after the ROD is signed (Section 2.36.2).

EPA acknowledges that during the first few days of the public comment period, the EPA e-mail for receiving comments ([harborcomments@epa.gov](mailto:harborcomments@epa.gov)) was not operational. We sincerely regret that inconvenience but want to clarify that these problems were fixed within a few days and the same day that these issues were identified, an alternate e-mail was quickly provided for commenters to utilize. EPA also moved quickly to grant another 30-day extension to the 60-day public comment period, for a total of 90 days.

EPA assures the public that all responses were read and evaluated as EPA developed a final cleanup plan in the ROD. Additionally, well before the public comment period opened, EPA anticipated that a large volume of comments would be received for the proposed plan. As a result, EPA ensured that sufficient EPA staff and EPA contractors were in place to maximize resources, efficiently process all comments received and provide the best technical skills for this project.

### 2.36.2 Improve Public Outreach After the ROD Is Signed

#### Comment Summary

Several people wrote about the need for continuing public outreach at the Site on specific topics. Many comments expressed a need for information to be shared with the community. Nineteen comments stated, “When the data are obtained for the remedial design, these must be shared with the community,” and “The community needs regular opportunities for input during the construction phase of the cleanup.”

The remaining comments were personal comments that touched on offers to help EPA with engagement, the need for multi-cultural education (especially about risks of eating fish and recreating in the river), engaging Portland citizens and those in outlying areas, remaining transparent, having accessible meetings, and communicating with the CAG during construction.

#### Representative comments

- “I will volunteer as much time and services as I can. I also propose an educational/celebratory event to take this opportunity to educate the public (young generations) about the underlying problems which have led to this pollution. i.e. sustainable living, human overpopulation and nourishing conscious evolution.”

- “I don't think these newcomers are being apprised of what they're exposing themselves and their children to. The area is a cancer hot spot. I have family members who have been afflicted by this and so I think that this needs to be included in the plan somehow.”
- The plan should call for an increase in culturally specific education and outreach to communities disproportionately impacted by the consumption of contaminated fish.”
- “The affected community around the Portland Harbor needs regular opportunities for input during the construction phase of the cleanup. These should be conducted at times of day and night which accommodate work schedules, provide childcare, and be conducted in accessible locations and languages.”
- “Your transparency so far has been good. Thank you. Please be transparent re the ongoing measurement of success of the toxicity removal.”
- “The ROD should contain a requirement for regular communication between EPA, DEQ and the CAG during the remedial design and construction phase of the cleanup. Residents are the largest group of stakeholders and those who literally own the river. They need to be included in all decisions about the river cleanup going forward.”
- “It is necessary that the public has a reliable way to stay informed on the progress of the cleanup and be engaged. The City would like to work with EPA and other government agencies to ensure the long-term Community Involvement Plan meets the needs of our communities. The City looks forward to partnership opportunities with EPA and other local government agencies to ensure community perspectives are understood and considered in every stage of cleanup process. The City request that EPA reevaluate its current Community Involvement Plan to ensure it meets the needs of the public, and in particular our most impacted communities. We also request that EPA dedicate additional resources for engagement that is conducted in a culturally responsive manner.”

### **EPA Response**

EPA intends to continue public outreach after the ROD is signed. Effective outreach is key to the successful implementation of a remedy, and we sincerely appreciate the public's interest, information requests, and offers to help. EPA will also explore making data from the monitoring events available online to the public as EPA has during pre-ROD early actions.

We also value our established relationship with the CAG, other community groups and individuals, the tribes and other interested parties. EPA will work to continue those relationships and seek input from those groups throughout the design and construction phases of remediation. These connections will be particularly important as we work out the best ways to communicate the risks of eating resident fish from the river. The input of these groups will be instrumental to help ensure that the public receives quality information and that risks are well understood.

Furthermore, we understand the concern over health issues in the area and the need to effectively communicate the health risks associated with the Site. EPA intends to work with Tribal and community groups, as well as other federal, state and local organizations to identify the best methods to communicate these risks such as through planned work on the use of fish advisories (see Section 2.28.1

of this responsiveness summary for more information about planned outreach on fish advisories), fact sheets one-on-one discussions and workshops.

Lastly, EPA is required to reevaluate the community involvement plan for the Site before the start of the remedy design and, as a result, EPA will be conducting additional community interviews. EPA hopes to hear additional feedback and ideas during these community interviews to help inform future public participation and risk communication work at the Site. EPA will also include the Oregon DEQ, the City of Portland, as well as other interested groups in the reevaluation of the community involvement plan prior to the start of the remedial design.

Additional information is provided elsewhere in this document on public participation as it relates to environmental justice issues (Section 2.35 of this responsiveness summary) and the use of fishing advisories (Section 2.28 of this responsiveness summary).

### 2.36.3 Be Transparent in Decision Making

#### Comment Summary

Transparency was an issue seen in many comment submissions. The commenters believed that EPA needs to do a better job in communicating the reasoning behind EPA's decisions and approaches.

More specifically, the proposed plan lacks transparency with respect to:

- Cost effectiveness analysis/weighing the costs against the benefits of the alternatives both individually and relative to each other
- Short-term impacts of dredging and fish advisories
- Human health risk assessment substantially overstates the actual site risk and therefore calls into question all of EPA's risk management decisions for the Site
- Collaborative and transparent process between EPA and the community related to the economic opportunity that will result from the cleanup activities
- Transparent stakeholder engagement and uncertainty analysis related to sustainability
- Costs of the cleanup on the community

#### EPA Response

Some transparency-related comments pertain to technical issues, which are better addressed under those specific themed responses to avoid duplicative effort. For comments related to the cost-effectiveness analysis, see Section 2.22.1 of this responsiveness summary. For comments related to short-term impacts, see Section 2.20 of this responsiveness summary. For comments related to the BHHRA (Kennedy/Jenks 2013), see Section 2.34 of this responsiveness summary.

EPA agrees that seeking input and collaborating with the community is vital for a successful implementation of the remedy, and community acceptance is one of the nine criteria that EPA is required to evaluate under CERCLA. EPA has sought to be fully transparent in its decision-making approach since the Site was listed. For instance, EPA has developed a collaborative relationship with the CAG, which formed in 2002 and is comprised of individuals from neighborhood associations; environmental, health, recreation, and business groups; and concerned citizens. The CAG provides a public forum for community members to learn about the Site and share community needs and concerns.

The CAG provided input and feedback to EPA and DEQ so that community perspectives were considered in the remedy selection process. Since 2002, EPA has continuously shared information and met with the CAG and the public about the Portland Harbor investigation and cleanup activities. EPA also has formed collaborative relationships with the tribes and other community groups involved with the Site over the years which also provided feedback and information to EPA on the proposed cleanup plan. A detailed list of EPA's collaborative efforts over the last few years is available in the 2016 *Portland Harbor Community Involvement Plan*.

Additionally, EPA conducted extensive community outreach in the months leading up to the release of the proposed plan (USEPA 2016c) and went well beyond the typical rollout of a proposed plan during the public comment period. In January, February, and March of 2016, EPA organized multiple community information sessions to inform the public about the Site and the forthcoming release of the proposed plan and public comment period. During the public comment period for the proposed plan, EPA held 4 public meetings and extended the public comment period to 90 days. EPA intends to continue public outreach after the ROD is signed. See Section 2.36.1 of this responsiveness summary for additional details about public outreach related to the proposed plan.

EPA assumes that the comment regarding the need for an “uncertainty analysis” for a sustainable remedy refers to the “uncertainty in risk and hazard estimates”. EPA performed an uncertainty analysis of each alternative to determine the likelihood that the alternative would be protective. This analysis was presented in Appendix I of the 2016 feasibility study report (USEPA 2016b).

EPA appreciates the concerns of the local workforce and businesses as important segments of the community. EPA is aware that other entities have been studying the economic impacts of the cleanup. For example, the City of Portland commissioned a 2012 economic study specific to the Superfund cleanup entitled *Economic Impacts of the Portland Harbor Superfund Site Cleanup* (Econorthwest 2012). A City of Portland press release described some of the findings from this study as: “clean-up will inject new spending into Portland’s regional economy and support jobs;” and “for every dollar spent on cleanup, more than a dollar in additional spending will be generated in the Portland economy as those employed in the cleanup purchase other goods and services in the region.” EPA believes that moving forward with the cleanup will enable properties to be more readily developed which in some cases have sat idle for years due to contamination issues.

## 2.37 Agency Roles and Cooperation

### 2.37.1 Require Federal Oversight of Cleanup

#### Comment Summary

Thirty-five comments were received indicating EPA should maintain federal oversight of the cleanup. Roughly 73 percent were form comments received by email and stated:

- “The US EPA should lead the cleanup effort after the ROD, not the State of Oregon.”

The remainder of the comments were personal comments expressing the same sentiment. They included:

- “Maintain federal oversight of Willamette River cleanup - do not delegate to the State of Oregon.”

- “Please do not pass responsibility for the clean-up to the state of Oregon. It is clearly EPA’s duty to lead this project for years and years. That is what we want from the national EPA”
- “We believe EPA should lead the cleanup implementation effort after the ROD, and not the State of Oregon. While Oregon has an important role to play as this cleanup plays out, we do not think they should be leading the cleanup process.”

The most detailed request came from the Audubon Society and read in part:

- “We understand some PRPs and potentially, the State of Oregon are encouraging EPA to turn over all or a portion of the oversight of the clean-up of Portland Harbor to the Oregon DEQ. Audubon strongly opposes any increase in the oversight role of DEQ and recommends that EPA assert strong oversight over the uplands that to date have been the primary responsibility of DEQ. We recognize that DEQ has an important role to play in the cleanup of Portland Harbor. However, that role should be subservient to EPA and any DEQ role should carefully defined in the ROD with clear benchmarks including timelines for implementation, outcomes and monitoring and that EPA should retain full oversight of DEQ activities. We are concerned that DEQ is far more susceptible to pressure from PRPs and politicians than EPA. It is also notoriously underfunded and subject to pressure and punitive action via the Oregon legislature through the budget process. Finally, DEQ is currently at an all-time low in terms of public trust and public confidence in Portland as a result of recent scandals involving air quality in our community. It is notable that confidence in DEQ is so low right now that Portland’s next Mayor, Ted Wheeler, has indicated that he may support the creation of a local air quality authority. Under these circumstances, it would be an unconscionable abrogation of EPA’s oversight responsibilities to transfer any additional responsibility to DEQ. EPA should not delegate its federal trust authority to the State of Oregon. We urge EPA to retain full oversight responsibility for the Cleanup of Portland Harbor and ensure that any role that DEQ plays within that context is explicitly defined with clear timelines and benchmarks for success, monitoring, transparency and public involvement under the supervision of EPA.”

### **EPA Response**

The Site NPL listing includes releases to the Willamette River and all upland sources of those releases. Roles and responsibilities for coordinating the cleanup and natural restoration of the Site are outlined in the 2001 MOU that EPA signed along with DEQ, six federal recognized tribes, National Oceanic and Atmospheric Administration, Oregon Department Fish and Wildlife, and the U.S. Department of Interior. DEQ was designated the lead for upland source control and EPA is designated lead agency for the in-river portion of the Site. Although MOU partners have participated and provided support in upland source control activities, development of the remedial investigation report (USEPA 2016a), feasibility study report (USEPA 2016b), and proposed plan (USEPA 2016c), EPA retains overall authority for the Site under CERCLA. At this time, it is anticipated that the roles established for DEQ and EPA in the MOU will remain the same in large part.

In order to maximize resources and achieve cleanup as soon as possible, there may be an opportunity for DEQ to perform certain technical oversight functions, in coordination with EPA, at specified areas of the in-river portion of the Site. Any oversight functions performed, whether performed by EPA or DEQ, will comply with CERCLA, the NCP, the ROD, any CERCLA agreements reached between the agencies and work parties.

## 2.37.2 Require DEQ Oversight of Groundwater Cleanup and Other Issues

### Comment Summary

Comments received on this topic are all from local businesses. Six comments said that the Oregon DEQ should be the lead agency for addressing groundwater. Five commenters wanted their current and/or previous source control measures to be included in the proposed plan, as well as DEQ's acceptance of the source control measures. Some commenters stated that COCs in groundwater at their facility do not pose a threat to the Willamette River, and that this has been accepted by DEQ. Five commenters also stated that the ROD should be written to exclude groundwater.

### EPA Response

Cleanup of contaminated groundwater originating in the uplands will continue to be managed by DEQ under a MOU discussed in Section 2.37.1 of this responsiveness summary which established the framework for roles and responsibilities for addressing the Site. Because groundwater plumes are known to or have the potential to extend into the river and may recontaminate sediments that have been remediated and may continue to load to surface water, EPA proposed and selected in-river actions to address contaminated groundwater, where appropriate. It is generally expected that upland source control of contaminated groundwater will be addressed at each facility before the in-river remedy occurs. Remedial design sampling will be required to establish the actual footprints of groundwater plumes in-river and may also confirm that some of the suspected plumes are not significant sources discharging to the river that would interfere with achieving the RAOs and cleanup levels for the Site.

Early source control actions conducted under DEQ authority are not final CERCLA actions. EPA will evaluate the effectiveness of DEQ source control actions with final cleanup objectives and determine if further action is warranted. If early source control actions meet the requirements of the ROD, EPA will not require further action. EPA cannot make such a determination in the feasibility study, as it predates the ROD, but EPA did assume that all sources, other than river banks, are controlled in the 2016 feasibility study report (USEPA 2016b). However, there may be upland groundwater plumes that have migrated beyond the upland control point and may need further control in-river (via a sediment cap or amendment to a sediment cap).

Site-wide monitoring will be conducted prior to remedy design and will include an evaluation of COCs in groundwater discharging to the Willamette River. A monitoring plan will identify appropriate points of compliance relevant to the site-specific circumstances. Although some source control evaluations reports may have concluded that groundwater at the facility is not discharging COCs to the Willamette River at concentrations above PRGs, these conclusions may not have been accepted by EPA.

For example:

- Attachment A of comments submitted by Brix presents the estimated extent of petroleum-contaminated groundwater at the facility; but the extent of the plume was only estimated and groundwater or pore water monitoring between the leading edge of the plume and the Willamette River was not conducted. It is unclear why the extent of petroleum-contaminated groundwater was not identified in the Brix source control evaluations.
- A weight-of-evidence evaluation was not completed for the Gunderson facility for groundwater. TPH-diesel was detected in the most recent round of groundwater monitoring at MW-77 at a concentration of 577 micrograms per liter; MW-77 appears to be located approximately 50 to 75

feet away from the Willamette River and indicating a complete pathway for COCs to the Willamette River.

- During review of the source control evaluations for Shore Terminals, EPA requested additional groundwater monitoring to demonstrate that the groundwater plume originating at the Fuel Loading Rack Area is not migrating to the Willamette River. Shore Terminals comment that *“According to the Oregon Department of Environmental Quality, groundwater at the Shore Terminals Portland Terminal (Facility) is not impacting the River and the ROD should not include a requirement for groundwater treatment (a reactive cap) offshore of the Facility”* did not include a reference to identify the source of DEQ’s decision; therefore, this statement cannot be evaluated. The Portland Harbor Upland Source Control Summary Report (DEQ 2016) describes that a source control decision has not been made for the Shore Terminals (ECSI #5130) and former ExxonMobil (ECSI #151) sites.

In response to specific commenters:

- A groundwater plume at the Knife River-Northwest facility was not identified in the proposed plan (USEPA 2016c).
- EPA acknowledges that source control measures at the Time Holding Co. facility were implemented to mitigate the groundwater pathway to the Willamette River, but a groundwater plume is still present and performance monitoring is ongoing.
- EPA acknowledges that source control measures at the Premier Edible Oils Site were implemented to mitigate the groundwater pathway to the Willamette River, but a groundwater plume is still present and performance monitoring is ongoing.
- DEQ is currently working with Gunderson to evaluate source control measures and groundwater monitoring is on-going.

Specific examples of when additional action may be needed to address groundwater include the Gunderson and Brix Maritime Co.’s (Brix) facilities.

- Gunderson has not conducted adequate sampling to characterize the nature and extent of the groundwater plumes at their property. For example, the source control evaluations report described trichloroethene at a maximum exceedance ratio of 102 times the Joint Source Control Strategy SLV at SWM-12; but adjacent monitoring wells were not sampled to delineate the extent of the groundwater plume. Further, there have been no source control actions taken at this property to control the groundwater plumes. Contaminants of concern will be monitored prior to remedial design to ensure that the pore water is not impacted such that a reactive layer in a cap or some other upland control may be necessary to ensure preliminary remediation goals are achieved.
- At the Brix facility, groundwater monitoring results are only discussed for monitoring wells outside of the groundwater plume in the source control evaluation report. Groundwater data for monitoring wells within the estimated extent of the groundwater plume should be presented to help characterize the potential threat to the Willamette River. Additionally, the groundwater monitoring wells downgradient of the plume do not appear to monitor the vertical extent of the contamination, and the vertical extent of contamination in soil (and likely groundwater) does not appear to have been delineated.

### 2.37.3 Retain DEQ as the Lead Agency for River Bank Source Control

#### Comment Summary

Many comments were received expressing concern that control of the river bank would shift from DEQ to EPA. Those comments are:

- RAO 9 should be removed. EPA violates the scope of the administrative order on consent by including RAO 9 (this should be covered under the remedial investigation/feasibility study work for uplands facilities). There is no data collected for this feasibility study report to provide a basis for analysis of alternatives with respect to river banks. Or baseline risk assessments were not performed for exposure to river bank soil. Or no information in the administrative record to support RAO 9 for river banks.
- Request that EPA honor DEQ's decisions in the source control evaluation process. Actions have already been performed under DEQ oversight. EPA should defer to DEQ and accept their decisions.
- In contrast to its approach to river banks, EPA properly sets no RAO for upland groundwater source control, given that it has determined that upland groundwater source control actions under DEQ oversight are still ongoing. Both river bank and groundwater media are being controlled under DEQ oversight, but EPA has arbitrarily and capriciously decided to treat them differently in the feasibility study and proposed plan. EPA should delete RAO 9 and all evaluations of alternatives based on river bank contamination, and treat river banks in the same way that it is treating upland groundwater.
- EPA is ignoring site-specific work performed under DEQ oversight for river banks. This will undermine DEQ's work and force business that have already passed DEQ's standards to face new and different demands from EPA. Requests that EPA not include river banks or groundwater remediation/remedial cleanup levels within the ROD.
- DEQ is the lead agency with respect to source control actions in Portland Harbor. River bank soils at the Arkema site have already been subject to extensive evaluation, as potentially erodible soils, with respect to COC identification, risk screening, and river bank: source control area identification. In December 2008, LSS submitted to DEQ the river bank: soil source control screening evaluation, which evaluated and identified areas for source control for the Arkema river bank. Comments on this river bank: source control screening evaluation were received from both DEQ and EPA. In 2012, river bank source control alternatives were evaluated as part of the EE/CA report for a removal action and concomitant source control measures (SCMs) at the Arkema site (Integral 2012, Appendix F; Attachment 1). There has been no subsequent correspondence on river bank: SCMs; however, there has been a general agreement with DEQ that the appropriate SCMs for the Arkema site will be conducted under DEQ's supervision, at the same time as or before the in-river remedy for the Site is completed. In keeping with the agencies' 2001 MOU with respect to roles on the Site, EPA must remove the reference to the areas requiring river bank remediation from the proposed plan. Also, in keeping with the method for addressing SCMs for other media (e.g. groundwater and storm water), EPA must reference DEQ plans for addressing upland river bank soils under these source control requirements, such as has been done for the Arkema site. Finally, if there are any data gaps that could affect the assessment of river bank SCMs, these must be clearly identified and addressed by DEQ as the lead agency.

**EPA Response**

The feasibility study report (USEPA 2016b) presents an evaluation of residual risk under long-term effectiveness as required by the NCP and EPA guidance. River bank soil and sediment pose a risk of recontamination to sediments. Therefore, river bank data provided by DEQ was included in the feasibility study report to facilitate the evaluation of long-term effectiveness.

Additionally, recent remedial actions with on-going performance monitoring were not described in the proposed plan (USEPA 2016c) on a site-by-site basis. Rather, DEQ's upland SCE information was used to identify river banks with known contamination. If performance monitoring concludes that the remedial action met the requirements of the ROD, EPA may not require further action to be taken to address the river bank.

EPA identified RAO 8, Migration of Contaminated Groundwater, for upland groundwater source control. Groundwater and river bank soil are being treated similarly, as described in the ROD. Ongoing source control efforts for groundwater and river bank soil will provide additional risk and recontamination reductions.

Responses for the last two comments are provided in LWG Dispute Issues 1d and 1q (Appendix A of this document).

**2.37.4 Ensure Interagency Coordination****Comment Summary**

Ten comments were received that requested increased cooperation between agencies (EPA and DEQ) and other entities (the City of Portland, Oregon Health Authority, and Multnomah County Public Health.) to make sure this project will be executed as safely and responsibly as possible. The sense is that this is currently not happening as well as it could. It was believed to be especially important for issues like fish advisories (through close collaboration with the Oregon Health Authority and Multnomah County Public Health) and continuing contaminant sources to the river. Compliance with the City's comprehensive plan and zoning were also mentioned. Issues with DEQ's earthquake safety plans for the tank farms in Linnton/Willbridge were also mentioned.

Representative comments include:

- "It is vital that city, county, state and federal agencies participate and coordinate the cleanup. Communication between agencies is currently not good. Time to learn to work together the way the rest of us do."
- "It is essential that the clean-up plan require a coordinated effort with local and state government, especially regarding effective communication of fish advisories through close collaboration with the Oregon Health Authority and Multnomah County Public Health."
- "Ensure with oversight that the Oregon DEQ has all source controls in place to prevent current and future contamination to the river. Example: The tank farms with 95 percent of all fuel sources are located in Linnton/Willbridge on liquefiable soils at the River edge without adequate earthquake proofing. Unacceptable is DEQ's answer: "We will deal with it when it happens." An earthquake would result in a huge environmental catastrophe and recontaminate the River."

- “EPA should work together with other government agencies to make sure this project will be executed as safely and responsibly as possible to protect the river for all citizens and wildlife. Please consider the community’s input before making a final plan.”
- “All local, state and federal authorities should coordinate together on an overall river basin plan to remove pollutant sources and protect the Willamette River for all citizens and wildlife.”
- “How are you interfacing with city of PDX and comprehensive plan and how the plan is healing this stretch of our river and increase access to river? Is the zoning compatible with healing the rivers?”
- “I’m concerned that DEQ is not an active partner in cleanup on shores connected with the river.”

### **EPA Response**

As described in Section 2.27.1 of this responsiveness summary, shortly after the NPL listing, EPA entered into a 2001 MOU with DEQ, six federal recognized tribes, National Oceanic and Atmospheric Administration, Oregon Department of Fish and Wildlife, and the U.S. Department of Interior. The MOU designated roles and responsibilities for coordination on the cleanup and natural resource restoration of the Site and established a Technical Coordinating Team comprised of MOU partner representatives. The team met at least monthly, frequently twice a month, and was the principle means of coordination and communication of data and information concerning Site management by the respective Lead Agencies, tribes, and Natural Resource Trustees, and to identify and resolve implementation issues. MOU partners worked closely on upland source control activities and the development of the remedial investigation report (USEPA 2016a), feasibility study report (USEPA 2016b), and proposed plan (USEPA 2016c). DEQ and EPA, in particular, have been closely coordinating over the last several years to develop a comprehensive cleanup that covers both the in-river areas and the upland properties. This includes work on the continued evolution of the Joint Source Control Strategy, to ensure the upland and in-river cleanups are coordinated to prevent recontamination of in-river work. DEQ also works with the City of Portland through an Intergovernmental Agreement for the administration of the stormwater program in Portland Harbor.

The Oregon Health Authority, in cooperation with Multnomah County Health Department, is responsible for outreach regarding the fish consumption advisories in effect for Portland Harbor. EPA coordinates its outreach efforts with Oregon Health Authority, DEQ, and the City of Portland to inform vulnerable communities of risks associated with contamination in the river and discuss city/state services that may be available to assist their needs. EPA also includes Tribal communities in its outreach efforts.

DEQ is lead regulator of the ongoing operation of the fuel terminals or “tank farms” adjacent to the Site. According to DEQ’s website, each fuel terminal has an emergency plan and coordinates with DEQ’s Emergency Response Program, the Portland Fire Department, the U.S. Coast Guard, and the Oregon Emergency Response System. Additional information about DEQ’s regulation of fuel terminals can be found at [www.deq.state.or.us/aq/northwest/gasTerminal.htm](http://www.deq.state.or.us/aq/northwest/gasTerminal.htm). EPA does not have the authority to change zoning, much of which is designated industrial or commercial along the Portland Harbor reach. EPA is aware of the City of Portland’s River Plan. EPA’s cleanup process considers reasonably anticipated future land uses in making its decisions and the cleanup will need to comply with federal and state environmental laws regarding minimizing impacts to habitat and compensating for any lost habitat.

## 2.38 Tribal Comments Received From the Public

### 2.38.1 Ensure Consultation and A Role in the Process

#### Comment Summary

Eighteen personal comments were received on this topic. Many of the commenters stated that there was a need to ensure consultation with the tribes in the decision making process and that they believed that consultation to date had been minimal, had not been heeded, and needed to be improved. The second topic was the need for the tribes to play a role (generally oversight) in the cleanup, as they were the people who have been most harmed by the contamination.

Representative comments are:

- “The Yakima nation stands against this and I stand with them. They were not properly included in this process and there is no evidence to support the idea that the plan has been designed or modified to meet their needs.”
- “Our native tribes are our river experts so it behooves you to co-operate and listen to them to clean up this Super Fund site QUICKLY AND THOROUGHLY!!!”
- “Tribal consultation appears to have been minimal. Or perhaps EPA has ignored previous comments of First Nations, including The Yakama Nation. We find it appalling that exposure and risk levels remain extremely high for subsistence fishers, and especially for tribal members, even after the so-called “cleanup” is completed. This shows no respect for the rights of tribes to eat fish and continue their cultural practices. This is unacceptable.”
- “I urge EPA to make significant revisions to strengthen the plan to reflect public feedback and the detailed responses of Tribal Nations. Tribal consultation has been minimal and weak. The Tribal Nations should be more enthusiastically and thoroughly engaged.”
- “I do not believe local tribes have been included fully enough in that plan's formulation. Also not acceptable.”
- “Tribal consultation and coordination need to be improved as it is almost none existent now.”
- “We strongly believe that EPA should allow Tribal Nations to have an oversight role in the cleanup process.”
- “Include the Yakama Nation and all local tribal entities of interest in the proposal. Language regarding the Yakama Nation and all local tribes of interest should be included in the plan, to reflect their role. tribes should be fully engaged and active participants in the Portland Harbor cleanup.”
- “Allow Tribal Nations an oversight role in the cleanup process.”
- “EPA must partner with tribal governments, urban native organizations, and other representatives of the most impacted communities in crafting an effective ROD that effectively restores the Portland Harbor, protects human health and the environment, and wins community acceptance. EPA's current plan does not do that, and must be abandoned. EPA must recognize that environmental restoration is not a discretionary function -- it a fundamental issue of justice at the heart of EPA's mission. Environmental restoration is necessary for the restoration of the

traditional cultures of the Pacific Northwest, who currently suffer from severe health problems as a result of the disruption of their traditional food sources -- including salmon, lamprey, and Wapato in the Portland Harbor. Finally, EPA must recognize that the customary uses of the Willamette River are protected under the Public Trust doctrine which governs EPA's actions, and which form the bed-rock of all statutory environmental law. In fulfilling these Public Trust duties, EPA is not permitted to behave arbitrarily. It must listen to feedback from the community, and even more importantly, from the Treaty Tribes and urban Native Americans who have a fishing tradition in this region stretching back over 10,000 years."

- "I think the cleanup should actually take its primary direction from those who have been most harmed by the pollution of the river. And that I think first and foremost is the tribes who've relied on it, who have lived here since the time of memorial."

### **EPA Response**

These comments are addressed by responses to formal comments submitted by the tribes. Please see Section 3 of this responsiveness summary.

## **2.38.2 Respect Treaty Obligations with the Yakama and Others**

### **Comment Summary**

A total of 318 postcards were received from the Yakama that read:

- "(The plan) completely ignores EPA's trust responsibility to protect the Yakama Nation's treaty rights. I am counting on EPA to uphold its trust responsibility, to honor our treaty and to deliver a plan that sustains the cultural practices of Yakama members and improves the quality of life for my tribe, our neighbors, and future generations."

Seven other commenters also wrote of the need to honor existing treaty obligations:

- "The Willamette needs to be a safe home for fish and aquatic life that are safe for humans and other animals to consume. It is our treaty obligation, as a country, to clean the Willamette to this standard."
- "We find it disturbing that cleaning up the mess made by industry ignores the fact that fundamental Indian treaties are being ignored. How can you ruin the basic food requirements of the original land owners?"
- "We need to uphold our treaty obligations."
- "We are now standing together to call on EPA to uphold our constitutional civil rights and our fundamental human right to a clean environment. We implore EPA to honor the federal government's treaties with tribal nations. The current proposed plan violates all of the above. This plan violates treaty rights by removing very little contaminated sediment, and by effectively relying on a perpetual health advisory for Portland Harbor fish. This means that fish are unsafe for Tribal members and others to consume, especially women of childbearing age, as well as pregnant women and nursing mothers, whose babies will experience neurological and developmental damage."
- "As you know, the Yakama Nation has said that the current plan would violate their 1855 treaty with the federal government, in particular their fishing treaty rights."

- “Honor the 1855 Treaty with the Yakama Nation. Protect the tribal members’ rights to fish in all usual and accustomed places, which includes the Willamette River. Clean up the Willamette River as much as humanly possible so the tribal members, and all others who fish the Willamette River have access to healthy safe fish.”
- “And the treaties that have been signed with those tribes prioritized access to traditional foods. And they would never have signed those treaties without that access. And those treaties are in Constitutional law. So that actually supersede CERCLA. So I think EPA needs to really humble itself before the advice and the direction of those tribes. And if they say the cleanup is inadequate, which they have, then it's inadequate. And that needs to be really taken very seriously. And EPA should go back to the drawing board to actually cleaning as much as they're asking. Yakima Nation, as well as a representative from Native American Youth and Adults, Robin White, who was just here, say that this cleanup plan represents a violation of their treaty rights, civil rights, and human rights. And that is a very serious charge. I think EPA needs to actually reflect on that and then come back with a plan that meets their qualifications that actually would provide the diet and the clean food from this river that they are requiring.”

### **EPA Response**

These comments are addressed by responses to comments submitted by the tribes. Please see Section 3 of this responsiveness summary.

## Section 3

# Tribal Comments and Responses

This section presents EPA's responses to written Tribal comments received by EPA during the 90-day public comment period. The comments are presented in this section by entity. The Five Tribes comments are presented first as they are the most comprehensive and responses to comments from individual tribes reference many of the responses prepared for the Five Tribes. The individual tribes are presented in alphabetical order.

Comments and responses are presented as follows:

- Five Tribes
- Confederated Tribes and Bands of the Yakama Nation
- Confederated Tribes of the Grand Ronde
- Confederated Tribes of Siletz Indians
- Confederated Tribes of the Warm Springs Reservation
- Nez Perce Tribe

Consistent with EPA's Policy on Consultation and Coordination and Indian Tribes EPA also held consultation meetings at tribal council locations from January 12 through February 4, 2016 and from July 19 through July 26, 2016, during the public comment period on the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c). In addition, representatives for the Confederated Tribes and Bands of the Yakama Nation met with Administrator McCarthy on July 26, 2016 in Washington, D.C. A summary of the consultation meetings, along with any written materials provided, are in the Administrative Record. Responses are contained in this section, or addressed by other comment responses elsewhere in this responsiveness summary.

The consultation process included discussions on treaty rights, in accordance with the February 2016 Guidance for Discussing Tribal Treaty Rights (Treaty Rights Guidance). The Treaty Rights Guidance was issued to provide assistance on consultation regarding EPA actions occurring in a specific geographic area where tribal treaty rights may exist in, or treaty-protected resources may rely on, that area. Responses to all comments received from tribal governments are contained in this section, or addressed by other comment responses elsewhere in this responsiveness summary.

## 3.1 Five Tribes

### 3.1.1 Require a Protective, Aggressive, and Large-Scale Remedy

#### Comment

Achieving a protective remedy within a reasonable timeframe will require an aggressive, large-scale remedy. The remedy should predominantly entail removal of contaminated sediments, rather than leaving the contamination in-place, and include the use of best management practices (BMPs) to minimize short-term impacts (e.g., those described in Sections 2.4.3.1 and 4.2.2.5 of the feasibility

study report and the special cases for NAPL and debris and structure removal noted in Sections 3.4.8.6 and 3.4.8.7, as well as those outlined in FWS and NMFS 2016). Much uncertainty remains about the timeframe for natural recovery. Thus, the remedy should not be overly dependent on natural recovery. Capping contaminated sediments in-place will be a necessary component of the remedy. However, due to the risks and limitations associated with capping, use of this technology should be limited to instances where contamination cannot feasibly be removed and the contamination can be safely contained.

**EPA Response**

Refer to Sections 2.6.1, 2.12.2, 2.13.1, 2.16.1, 2.19.1, and 2.34.1 of this responsiveness summary.

**3.1.2 Establish a Timeframe in Which to Meet RAOs****Comment**

A timeframe must be established by which to meet all RAOs and associated acceptable risk levels (i.e., PRGs). Although the Five Tribes advocate for a remedy that will achieve cleanup goals as quickly as possible, we acknowledge that natural recovery is a necessary part of the remedy. The selected remedy should have a very high likelihood of achieving cleanup goals within 10 years following construction. After decades of contamination, we should not have to wait any longer than absolutely necessary for a clean river. The uncertainty of natural recovery processes at the Site further underscores the importance of selecting a remedy that does not rely on a lengthy (i.e., more than 10-year) recovery period following construction.

**EPA Response**

See Section 2.24, 2.17.1, 2.21, and 4.1.1 of this responsiveness summary.

**3.1.3 Use MNR and ENR Judiciously****Comment**

We acknowledge that, for practical purposes, the remedy will need to rely in part MNR, ENR, and sediment capping. However, these technologies should be used judiciously. The hydrodynamics of the Willamette River are complex, and even areas that are primarily depositional also erode. The inability of EPA and LWG to develop a hydrodynamic and sediment transport model that accurately predicts deposition and erosion highlights this complexity. Because tools are not available to accurately predict deposition and erosion on a fine spatial scale, we cannot assert the degree to which natural recovery processes will occur. Thus, EPA must use the environmentally protective assumption that natural recovery will be limited. MNR and ENR must not be used in erosional areas and must only be used in areas of low contamination. MNR should be used only in depositional environments.

**EPA Response**

EPA will update the data through focused remedial design sampling activities at the Site. Remedial design sampling data will be used to apply the decision tree in the ROD and to refine the footprint of areas that will be targeted for capping, enhanced natural recovery, and in-situ treatment and to refine the volume of material that will be targeted for removal through dredging and excavation. In addition, long-term monitoring will be performed to monitor the effectiveness of the remedy to achieve the remedial action objectives established for the Site. See also Sections 2.16 and 2.19.

### 3.1.4 Recognize Issues with Capping

#### Comment

Capping contaminated sediments in-place can be a practical, even necessary solution in certain circumstances. Sediment caps, however, come with risks, costs, and limitations. The dynamic nature of the Willamette River presents challenges in designing and maintaining a permanent cap. Bathymetric surveys and other data collected over a ten-year period or less may not be indicative of river conditions in the long term. Further, the effectiveness of even comprehensive monitoring has its limitations: breaches in cap integrity may not be immediately detected and may re-contaminate the area. With climate change, large-scale climatic events, a Cascadia Subduction Zone event, and other uncertainties, there is a very real possibility that leaving contamination in place will result in re-releases over long timescales, such as 100 years or more, to the detriment of future generations.

#### EPA Response

Refer to Section 2.13.1 of this responsiveness summary.

### 3.1.5 Explain Long-Term Management of Sediment Caps

#### Comment

EPA will update the data through focused remedial design sampling activities at the Site. Remedial design sampling data will be used to apply the decision tree in the ROD and to refine the footprint of areas that will be targeted for capping, enhanced natural recovery, and in-situ treatment and to refine the volume of material that will be targeted for removal through dredging and excavation. In addition, long-term monitoring will be performed to monitor the effectiveness of the remedy to achieve the remedial action objectives established for the Site. The Five Tribes are concerned with any entity's ability to manage a cap in perpetuity. Indeed, EPA has only been in existence for 45 years. Thus, there are no examples of EPA successfully managing sediment caps for long timescales. We are concerned with whether the relevant entities (the responsible parties and EPA) will even exist 100 years from now, and whether funding and political willpower will be available for monitoring and maintenance.

#### EPA Response

Refer to Sections 2.17 and 2.19 of this responsiveness summary.

### 3.1.6 Do Not Let Convenience and Cost Savings Bias Use of Caps

#### Comment

We are also concerned about the restrictions on river use that would result from capping significant portions of the Site. Capping would permanently restrict future development in the river, including placement of structures and dredging. The upcoming remedy is EPA's chance to clean up the river – likely its only chance – for the use of future generations. EPA should therefore focus on developing a remedy not only that will protect human health and the environment but that will not significantly limit uses of the river in the future. We strongly urge EPA to adopt a remedy that does not rely on capping for mere convenience and cost savings, but rather is focused on removing the contaminated material wherever practicable.

#### EPA Response

Capping will only occur consistent with future land uses, and will not restrict the tribes' ability to fish or collect shellfish, for example. Refer to Sections 2.13 and 4.1.5 of this responsiveness summary.

### 3.1.7 Limit the Need for ICs

#### Comment

An aggressive, removal-focused remedy is desirable because it will limit the need for MNR and ICs, both until PRGs are achieved and in perpetuity. In addition to the uncertainties associated with the success of MNR and the potentially lengthy time period required to achieve PRGs, MNR requires “significant administrative effort over the long term to oversee and coordinate sampling, data evaluation, and future additional actions, if any are needed” (USEPA 2016b, p. 4-40). Thus, MNR may be an easier solution than removal in the short term but requires significant effort in the long term. EPA also acknowledges that ICs are of limited effectiveness. For instance, EPA states that fish consumption advisories “are not enforceable and are generally understood to have limited effectiveness,” should “be relied upon to the minimum extent practicable,” and do not protect the ecological receptors themselves (USEPA 2016b, p. 4-12 and 4-88). Land use restrictions are also of limited effectiveness, as they “are difficult to monitor in a river environment” (USEPA 2016b, p. 4-12).

#### EPA Response

Refer to Sections 2.28.3, 2.31, 4.1.1, and 4.1.2 of this responsiveness summary.

### 3.1.8 Do Not Leave PTW that Cannot Be Reliably Contained

#### Comment

No NAPL or PTW that cannot be reliably contained (NRC PTW) should be left in the river, as these materials can migrate and act as a source of ongoing contamination. The Five Tribes are not in favor of capping these materials, no matter how engineered the cap is. These materials may migrate horizontally, either now or in the future when environmental conditions, such as hydrology, change. Any structures impeding dredging of these materials should be seriously evaluated for the feasibility of removal. In addition, NAPL and NRC PTW at depth should be dredged using all available means. These materials should only be capped if under a structure that cannot be removed or if located too deep for best available technology to reach.

#### EPA Response

See Sections 2.5, 2.13, and 2.21 of this responsiveness summary.

### 3.1.9 Do Not Increase PRG Values in the ROD

#### Comment

We understand that EPA has the ability to change PRGs as they become final cleanup levels in the ROD. The PRGs are generally based on sound science and ARARs, and we strongly urge EPA not to increase these values in the ROD. Certain parties, such as LWG, have questioned the validity of the polycyclic aromatic hydrocarbon (PAH) PRGs, specifically. We support the existing PAH PRGs, which are based on Site-specific risk calculations.

#### EPA Response

PRGs developed for the proposed plan (USEPA 2016c) are now updated as appropriate and included in the ROD as final cleanup levels. Based on future data collection, EPA will evaluate issues of technical impracticability in achieving these levels on a case by case basis. Also refer to Section 2.3 of this responsiveness summary.

### 3.1.10 Do Not Issue ARAR Waivers

#### Comment

We acknowledge that it is possible that certain cleanup goals based on background concentrations may never be met at the Site due to inputs from outside Site boundaries (e.g., upstream, upland). The Five Tribes do not support the issuance of an ARAR waiver (e.g., based on technical impracticability) at this time, and believe that EPA is making appropriate steps to issue a ROD without such a waiver. Technical impracticability waivers do not adequately protect treaty-protected rights and resources. (Treaty-protected rights and resources, while not explicitly referenced in the remainder of this document, are relevant to any discussion of the adequacy of the cleanup.) EPA should adopt a remedy that is likely to achieve cleanup goals. After remedy construction, progress toward cleanup goals should be monitored periodically, and the success of the remedy should be evaluated during five-year reviews. If the Site is not on target to achieve cleanup goals, the need for additional remediation (through a ROD amendment) should be seriously considered, in consultation with MOU partners. A decision to issue a waiver would require: (a) a robust, long-term monitoring dataset (covering the period from construction completion through at least 10 years post-construction) that indicates that certain COC concentrations in specific media remain at steady-state concentrations above PRGs, and (b) a determination based on thorough analysis that additional active cleanup and/or additional source control cannot be undertaken. The Five Tribes expect to be full participants in any evaluations or decisions related to consideration of technical impracticability or other ARAR waivers.

#### EPA Response

EPA agrees that there is insufficient information at this time to waive any ARAR and have not done so in the ROD. Please see Section 2.3.1 of this responsiveness summary.

### 3.1.11 Address Community Concerns Through BMPs and Monitoring

#### Comment

The Five Tribes are hopeful that community concerns about construction impacts can be addressed through BMPs and monitoring. The cleanup of this important resource, a cleanup that will benefit countless future generations, should not be compromised for the sake of immediate convenience (i.e., avoiding short-term construction impacts). Anticipated construction impacts are myriad and include potential air quality impacts, increased vehicular and vessel traffic, noise, odor, and lights. EPA should work with local communities to try to address their concerns to the extent possible while still achieving stringent cleanup objectives in a timely manner. BMPs should be used to control these impacts (Section 4.2.2.5 of the feasibility study report), and monitoring for impacts to human health should be rigorously conducted, with adaptive management employed if monitoring indicates unacceptable human health risks.

#### EPA Response

Refer LSS Dispute Issue 16 (Appendix A of this document) and Sections 2.8, 2.14.3, 2.20, and 2.21 of this responsiveness summary.

### 3.1.12 Select a Version of Alternative G

#### Comment

Based on the priorities described above and a technical evaluation of the proposed plan and feasibility study, the Five Tribes support a version of Alternative G (with modifications noted herein). Primarily, we support the use of Alternative G RALs, but request specific changes to the technology assignment methodology and technology applications.

Although we support elements of Alternative I, the alternative relies too heavily on uncertain natural recovery processes and leaves too much contamination in the river, posing human health and environmental risks in both the short and long term. By EPA's own interim target analysis, Alternative I is not expected to achieve cleanup goals within a reasonable timeframe and is therefore not protective of human health or the environment. As described below and by EPA's own evaluation of the evaluated alternatives, only Alternative G meets the two threshold criteria of "Overall Protection of Human Health and the Environment" and "Compliance with ARARs." Therefore, the greater cost and construction duration (which contribute to the evaluation of balancing criteria) of Alternative G compared to other alternatives should not be the basis for rejecting Alternative G. Of the alternatives that EPA carries forward to detailed analysis, EPA must select Alternative G.

### **EPA Response**

As stated Section 4.3 and shown in Table 4.3-3 of the feasibility study report (USEPA 2016b), Alternatives E, F, G and I all meet the two threshold criteria of Overall Protection of Human Health and the Environment and Compliance with ARARs. While Alternative G may have the most reduced long-term risks, the feasibility study selected Alternative I in part due to its superior ability to minimize short-term disruption and risks. The selected alternative, Alternative F Modified reduces long-term human health risks more quickly than Alternative I and minimizes reliance on ICs. Refer to Sections 2.6 and 2.31 of this responsiveness summary.

In assessing the various Alternatives EPA also looked at the Willamette River watershed as a whole, to determine the feasibility of providing a cleanup response that would effectively improve water quality to the level that is protective of ecological receptors and human consumers of fish and shellfish. The cleanup in this action is restricted to approximately a 10-mile segment of the Willamette River and upstream contamination from past and current permitted industry is not being addressed at this point. These facts further supported EPA's decision to pursue Alternative F Modified, rather than any other proposed remedies.

### **3.1.13 Use PRGs as Cleanup Levels in ROD**

#### **Comment**

We support the PRGs and advocate for their use as cleanup levels in the ROD.

#### **EPA Response**

Comment noted. EPA did not change any of the PRGs from the proposed plan (USEPA 2016c), and they are the final cleanup levels in the ROD.

### **3.1.14 Retain EPA's Definition of PTW for the Site**

#### **Comment**

We support EPA's definition of PTW for the Site. PTW should be defined, in part, based on calculated risk. PTW defined by higher contaminant concentrations at other sites is not relevant to EPA's definition of PTW at this Site.

#### **EPA Response**

Comment noted. See Section 2.5 of this responsiveness summary.

### 3.1.15 Include River Banks in Remedy

#### Comment

We support EPA's inclusion of river banks in the remedy. Including river banks gives EPA authority to direct cleanup work (in the form of excavation and capping) to prevent recontamination of the Site. Although the DEQ has historically had jurisdiction over river bank cleanup along the Site, the addition of river banks to the remedy prevents any disconnects between EPA and DEQ's work, such as delays in river bank cleanup beyond the Site cleanup. EPA is not ignoring or undermining any of DEQ's upland efforts by doing so, and we understand that additional data (e.g., remedial design or post-construction monitoring data) may show that certain river banks and groundwater plumes originally slated for remediation under the Site-wide cleanup may no longer need active cleanup. We urge EPA and DEQ to continue to work closely to ensure that cleanup under the remedy does not unnecessarily conflict with past or ongoing river bank work or create an unnecessary burden for the responsible parties.

#### EPA Response

Comment noted. The ROD includes river banks as proposed in the proposed plan (USEPA 2016c).

### 3.1.16 Use BHHRA Fish Consumption Rates

#### Comment

We support the fish consumption rates used in the BHHRA (Kennedy/Jenks 2013) and carried forward to the feasibility study. Consumption rates in Oregon are typically higher than elsewhere in the country, including for tribal fishers (FWQC 2013; CRITFC 1994). The rates used in the BHHRA accurately reflect this reality

#### EPA Response

Comment noted.

### 3.1.17 Reject LWG's Hydrodynamic and Sediment Transport Model

#### Comment

We support EPA's rejection of LWG's hydrodynamic and sediment transport model. As outlined in Appendix H of the feasibility study report, the model over-predicted the amount of deposition occurring within the Site, which in turn overstates the potential success of MNR (USEPA 2016b). The model failed to properly link the sediment transport model with the hydrodynamic model. It also did not sufficiently address the effects of wind- and wake-generated erosion, which are likely to be significant for the Site, and did not address bedload transport.

#### EPA Response

Comment noted.

### 3.1.18 Use the Current Portland Harbor Dataset

#### Comment

We support EPA's use of the current Portland Harbor dataset for the purposes of the feasibility study and proposed plan, which includes data from 1997 through 2011. Although data are not strictly recent, collecting additional data to update the database at this time would only serve to delay progress in implementing a remedy. New baseline data must be collected for remedial design and will serve a similar purpose to data that would be collected now.

### **EPA Response**

Comment noted.

### **3.1.19 Reject Alternatives B and D as They Are Not Sufficiently Protective**

#### **Comment**

We support EPA's determination that Alternatives B and D are not sufficiently protective of human health or the environment (e.g., EPA 2016a, p. 50).

### **EPA Response**

Comment noted.

### **3.1.20 Use BMPs as Needed**

#### **Comment**

We are generally supportive of the BMPs that EPA proposes to minimize impacts to local communities and the environment.

### **EPA Response**

Comment noted.

### **3.1.21 Use A Cover Layer to Control Residuals After Dredging**

#### **Comment**

We support the placement of a thin layer cover immediately following dredging in order to control residuals.

### **EPA Response**

Comment noted.

### **3.1.22 Explain How Alternative I Meets the Protectiveness Criterion**

#### **Comment**

According to Superfund regulations (40 CFR 300.430) and guidance (e.g., EPA 1988, 1990), EPA must evaluate alternatives against two threshold criteria, as well as five balancing criteria. Typically, the two threshold criteria must be met in order for an alternative to be selected. The two threshold criteria are "Overall Protection of Human Health and the Environment" and "Compliance with ARARs." In the feasibility study, EPA evaluates the first of these threshold criteria based on whether each alternative meets "interim targets" for each RAO. Interim targets are goals set for the time period immediately following construction completion. If an alternative is expected to meet interim targets post-construction, the alternative is assumed to meet cleanup goals within a reasonable timeframe. For this Site, EPA defines a reasonable timeframe to be 30 years (measured from the start of construction). EPA's comparison of alternatives to interim targets concludes that Alternative I only meets two out of the five measurable interim targets. Based on EPA's own definition of interim targets, Alternative I is therefore not expected to meet cleanup goals within 30 years and thus does not meet the "Overall Protection of Human Health and the Environment" criterion. EPA errs when it concludes that Alternative I meets this criterion. Of the alternatives evaluated, only Alternative G meets all measurable interim targets.

### **EPA Response**

EPA has revised its preferred alternative to Alternative F Modified. Alternative F Modified relies on application of the same remedial action levels (F RALs) throughout the Site with the exception of the navigation channel where the remedy will target PTW and sediment contamination exceeding the Alternative B RALs. The modifications for the navigation channel are appropriate because the risk exposures and physical conditions in the channel are different from the rest of the Site. The levels of contamination in the navigation channel are lower than in nearshore and intermediate areas of the River. Exposure to contaminants in the channel is limited since the depth of the channel is greater than 30 feet and based on information gathered during the remedial investigation, the understanding is that most of the fish species feed in the shallower areas of the Site. Refer Sections 2.6, 2.7, and 3.2.5.

### **3.1.23 Explain Why Alternative G Was Rejected as It Is the Only Alternative to Meet ARARs**

#### **Comment**

EPA determined that all alternatives except Alternative B meet the second threshold criterion, “Compliance with ARARs.” Given that many PRGs are based on chemical-specific ARARs, if the interim target analysis determines that an alternative will not meet PRGs within a reasonable timeframe, it logically follows that the alternative also does not comply with ARARs. Therefore, based on the above comment, the only alternative that complies with ARARs is Alternative G. Thus, Alternative G is the only alternative that meets the two threshold criteria and is the only defensible alternative. The higher cost and greater construction impacts of Alternative G compared to other alternatives should not be a reason for rejecting Alternative G.

### **EPA Response**

As stated in Section 4.2.2.2 of the feasibility study report (USEPA 2016b), Alternative B would be unlikely to meet chemical-specific ARARs in a reasonable timeframe. However, all other alternatives would meet chemical-specific (and all other) ARARs because of the reduced reliance on MNR. See Sections 2.1, 2.3, 2.6, and 2.31 of this responsiveness summary.

### **3.1.24 Defer to the Most Environmentally Protective Alternative**

#### **Comment**

We acknowledge that EPA’s ability to determine whether and when alternatives will meet cleanup goals in the absence of an accurate natural recovery model is very limited. We appreciate EPA’s attempt to evaluate the ability to meet PRGs based on the interim target concept, which sets targets for cleanup post-construction, a point at which it is easier to predict sediment concentrations because an understanding of natural recovery is not required. We are concerned, however, about the selected interim targets. EPA does not justify why meeting these particular interim targets post-construction ensures that the alternative will meet cleanup goals after 30 years. The selection of the RAO-specific interim targets appears random and not rooted in science. Thus, we do not have confidence in this approach. Lacking a better approach, EPA must defer to the most environmentally protective option, Alternative G. Coincidentally, a strict application of EPA’s interim target approach also supports the conclusion that Alternative G is the only defensible alternative, as explained above.

### **EPA Response**

Interim targets were developed using a model called SEDCAM. The SEDCAM model outputs are a single line of evidence among several other lines of evidence (bathymetry, percent fines, propeller wash areas, wind/wake conditions, and subsurface to surface sediment concentration ratios) used to

forecast the achievement of interim targets, all with high degrees of uncertainty in a dynamic and complex river system. Given this uncertainty, EPA will focus greatly on the development of a robust monitoring plan following the ROD to evaluate progress towards cleanup levels with empirical data. The SEDCAM modeling results show that the selected remedy, Alternative F Modified, is protective within a reasonable timeframe given the uncertainty in the model.

### 3.1.25 Let Long-Term Protection Drive the Decision Process

#### Comment

Aside from our assertion that Alternative G is the only alternative carried forward for full evaluation that meets the two threshold criteria, the substantial reductions in risk afforded by Alternative G further justify the selection of this alternative. The figures and tables in Section 4.2 of the feasibility study report illustrate these reductions. The Alternative G risk reductions are especially apparent when the data in Section 4.2 tables are graphed (Attachment 1). Although we advocate for Alternative G, we note that there are also substantial risk reductions between Alternatives E/I and F, highlighting the superiority of Alternative F over Alternatives E and I. EPA's decision to select Alternative I over alternatives that have clear risk reduction benefits is based on a value judgment of the relative importance of short-term construction impacts and cost compared to long-term protection of human health and the environment. The Five Tribes strongly believe that long-term protection of human health and the environment should drive the remedy decision; Alternative G is therefore the best alternative of those evaluated by EPA.

#### EPA Response

Evaluation of alternatives under CERCLA includes an evaluation of both short and long-term impacts of the remedy. These impacts are further explored under the Clean Water Act 404 analysis attached to the feasibility study report (USEPA 2016b). Through this analysis it was apparent that construction of a cleanup taking decades longer than the selected Alternative F Modified would result in unacceptable benthic impacts over an extended duration of time. Rather than a "value judgement," this finding is an appreciation of the real temporal impacts from such aggressive, extended duration cleanup alternatives that outweighed the incremental longer term gains of such alternatives. Also refer to Sections 2.1, 2.3, 2.6, and 2.31 of this responsiveness summary.

### 3.1.26 Consider Alternative G Which Meets the Protection Goal in 10 Years

#### Comment

As noted in the Pathway for Achieving Vision section above, we support a remedy that is expected to achieve protection within 10 years following construction, not 30 years from the start of construction. According to EPA, Alternative G would achieve protection in 11 years following construction (i.e., the remedy would be protective 30 years following the start of construction, with a 19-year construction duration). Thus, Alternative G nearly meets our objective of achieving protection within 10 years following construction. According to EPA's analyses, the other alternatives do not.

#### EPA Response

For the SDUs where active remediation through capping and dredging takes place, sediment concentrations will approach the remedial cleanup levels immediately following construction (approximately 13 years). In the remainder of the Site, MNR is expected to reduce sediment concentrations to the remedial cleanup level within approximately 30 years to be confirmed in post-construction monitoring.

### 3.1.27 Do Not Choose a Middle Ground Remedy by Default

#### Comment

Table 15 of the proposed plan attempts to compare the performance of each alternative against the two threshold criteria and five balancing criteria. For this exercise, a qualitative approach is used to rank alternatives from “least” (worst) to “best” for the five balancing criteria. Alternatives are ranked progressively “better” or “worse” (with the exception of “Short-Term Effectiveness”; see comment below). For instance, for the “Long-Term Effectiveness and Permanence” criterion, G is ranked better than F, which is better than E, which is better than D, which is better than B. With the exception of I, which is always ranked the same as E, no two alternatives receive the same ranking. This approach leads to a bias toward selecting the remedy in the middle (E and I are in the middle of the other alternatives) because EPA is trying to “balance” the “Short-Term Effectiveness,” “Implementability,” and “Cost,” all of which get “worse” with increasingly aggressive remedies, against “Long-Term Effectiveness and Permanence” and “Reduction of Toxicity, Mobility, or Volume through Treatment,” which get “better” with increasingly aggressive remedies. EPA should not base its decision on a system that by default selects the middle remedy. The middle remedy is not by definition the best remedy.

#### EPA Response

EPA has sought to provide a balance of achieving the most reduction in risk to people and aquatic organisms through a protective cleanup while reducing short-term and overall impacts to the environment, the community, and workers during and after construction. Per EPA guidance, short and long-term risks were not looked at as tradeoffs, but rather as part of a holistic view of alternative evaluation. While Alternative G may have the most reduced long-term risks, the proposed plan (USEPA 2016c) selected Alternative I in part due to its superior ability to minimize short-term disruption and risks. The selected alternative in the ROD, Alternative F Modified reduces long-term human health risks more quickly than Alternative I and minimizes reliance on ICs.

### 3.1.28 Rescore the Short-Term Effectiveness Criterion

#### Comment

EPA notes that the “Short-Term Effectiveness” balancing criterion includes both the short-term environmental and community impacts during construction and also the environmental and human health impacts of the Site until RAOs and PRGs are attained (USEPA 2016b, p. 4-13). Both of these components of the criterion are discussed in the detailed analysis of alternatives (USEPA 2016b, Section 4.2). However, the scoring in Table 4.3-3 of the feasibility study report appears to consider primarily the short-term impacts during construction, an approach that favors the less aggressive alternatives (e.g., Alternative G was scored worst). Though we agree that the construction impacts during the four-month in-river work window of each year would be greatest under Alternative G, this alternative would achieve cleanup levels the fastest and would therefore present the least human health and environmental risks in the short term. This is an important point because, as indicated in the comment above, EPA appears to arrive at Alternative I by weighing the two balancing criteria that favor more aggressive cleanups against the three that currently favor less aggressive remedies. If the “Short-Term Effectiveness” criterion is re-scored as we propose here, the evaluation would correctly tilt toward a more aggressive cleanup.

Presumably, EPA’s “moderate” (rather than “best”) ranking of Alternative B accounts for the fact that this alternative would have the fewest construction impacts but the greatest impacts post-construction. However, the ranking of the other alternatives does not appear to penalize alternatives for impacts post-construction. We also disagree with the designation of Alternatives E and I as

“better”, while Alternative F receives a “low” rank. Even if EPA is scoring these alternatives based only on construction impacts, we do not believe that the moderate increase in construction time and footprint between Alternatives E/I and F justifies this large jump.

#### **EPA Response**

Refer to Section 2.20 of this responsiveness summary.

### **3.1.29 Give Less Weight to Benthic Impacts During Construction**

#### **Comment**

EPA appears to justify selecting Alternative I over Alternative G in part because the latter alternative “impacts [benthic] habitat for the longest period of time during construction (19 years) and would take the longest time for benthic populations to recover due to the large area of habitat impacted (776 acres)” (USEPA 2016a, p. 60). While dredging and capping do disturb benthic habitat during the duration of the disturbance, benthic organisms tend to recolonize within a period of several years following the end of disturbance (e.g., Wallace 1990; Lamberti et al. 1991). The duration of disturbance of any given area of benthic habitat would depend on how work is sequenced. If, for instance, remediation is conducted from upstream to downstream, the remediated areas would have the opportunity to recolonize as equipment moves downstream. In that case, the duration of impact of any given area would be expected to be significantly less than 19 years.

Further, EPA frequently refers to the greater impact to the environment and benthic community of Alternatives F and G compared to Alternatives E and I (e.g., EPA 2016a, p. 66; EPA 2016b, p. 4-98 and p. 4-100). While we assume that EPA intends to refer to short-term construction impacts only, the language as written is misleading. Overall, Alternatives F and G will have a more positive impact on the environment and benthic community due to greater risk reduction following construction and a shorter time to achieve cleanup goals.

#### **EPA Response**

EPA agrees that disturbance of benthic populations would depend in part on sequencing, and that benthic populations can recover relatively quickly. Mitigation measures and best management practices will be implemented to minimize impacts on benthic populations to the extent possible, and remedial implementation planning would consider sequencing, timing, and other factors. Impacts on benthic populations are just one of the short-term effects that were considered in the alternative evaluation.

EPA has selected its preferred alternative to Alternative F Modified as its final remedy, which will achieve risk reduction in a shorter time compared to Alternative I, and relies less on MNR. See also Sections 2.1, 2.6, 2.31, and 2.34 of this responsiveness summary.

### **3.1.30 Consider Alternative F or G Based on Greater Risk Reduction**

#### **Comment**

In relation to removing contaminated sediment and river bank soil and transporting it through local communities, EPA argues that “Alternatives F and G would impose significantly greater impacts to the environment and community and have much greater costs (1.5-2 times more than Alternatives E and I) that are not commensurate with the additional risk reduction relative to Alternatives E and I” (USEPA 2016a, p. 60; USEPA 2016b, p. 4-99). Although Alternatives F and G may have greater short-term impacts and costs compared to Alternatives E and I, EPA does not sufficiently justify that these

impacts are not commensurate with the additional risk reduction. We believe that the greater risk reduction does justify the additional construction impacts and costs of Alternatives F and G.

#### **EPA Response**

EPA has selected Alternative F Modified for its final remedy. See also Sections 2.1, 2.6, 2.31, and 2.34 of this responsiveness summary.

### **3.1.31 Address Issues with Presentation of NAPL and PTW Areas**

#### **Comment**

The feasibility study also does not clearly present the amount of NAPL and NRC PTW material that is expected to remain in place by alternative. This information is distinctly different from the amount of PTW addressed by each alternative (e.g., EPA 2016b, Table 4.2-9), and is not easily determined through the use of existing tables and information. We ask EPA to clearly present this information.

#### **EPA Response**

Refer to Sections 2.5, 2.10, and 2.14 of this responsiveness summary. EPA did not establish any boundaries of waste in the 2016 feasibility study report (USEPA 2016b). EPA developed estimates of various types of waste based on existing information to estimate costs in the feasibility study. The figures show the extent of the evaluation based on various assumptions identified in the feasibility study report. The extent of the RAL boundaries and cap designs will be established in remedial design. EPA agrees that additional data collection during remedial design will be required to determine the appropriate design and waste treatment and disposition requirements.

EPA used a robust data set provided by LWG, including sediment data collected as recently as 2013 and fish tissue data collected as recently as 2012, to develop the alternatives in the 2016 feasibility study report. The data set includes 2,259 surface and 975 subsurface sediment samples collected during the remedial investigation and various early action efforts to characterize the nature and extent of contamination. EPA does not believe there are any errors or omissions in the CSM and that the information used in the 2016 feasibility study report is sufficient to develop and select a remedial alternative. However, EPA acknowledges that additional data will be collected during remedial design. These data will be used to support establishing remedial action footprints, technology assignments, use restrictions or other ICs, treatment and disposal of dredged material, mitigation requirements, among others.

### **3.1.32 Expand SMAs**

#### **Comment**

The Five Tribes appreciate the addition of the GeoPDF to EPA's Portland Harbor Superfund website, which allows users to overlay various data layers presented in the feasibility study, such as sediment contaminant concentrations and technology assignments for each alternative. The GeoPDF begins to address the concern we have expressed previously regarding our inability to readily determine whether non-focused COCs are adequately addressed by the proposed remedy. Because high concentrations of focused COCs (i.e., COCs for which RALs are developed, including PCBs, DDx, total PAHs, PeCDF, PeCDD, and TCDD) and non-focused COCs are generally co-located, areas designated for active remediation (i.e., sediment management areas, or SMAs) based on focused COC concentrations also tend to address areas of high concentrations of non-focused COCs. However, there are a few areas where this is not the case. For example, high concentrations of arsenic in surface sediment exist on the east side of the McCormick & Baxter cap, but this area is not assigned any active remediation under

Alternative I. In contrast, Alternative G would require dredging with a cap in this area. Similarly, high concentrations of chromium and copper in surface sediments (and copper in subsurface sediments) are located at the north end of the RM 6.5E SDU, an area that is assigned MNR under Alternative I. Alternative G would require capping and dredging of this area. These observations support our preference for selecting Alternative G as the preferred alternative. If EPA selects a remedy less protective than Alternative G, we request that EPA expand SMAs to address areas exhibiting high concentrations of non-focused COCs, such as the examples we have described.

In addition to the examples described above, we note several areas of relatively high non-focused COC concentrations that fall outside SDUs and are therefore assigned MNR for all alternatives. For instance, high concentrations of several contaminants (e.g., bis(2-ethylhexyl) phthalate in surface sediment) exist in the east-most portion of Swan Island Lagoon. However, this area is not included in the Swan Island SDU. In addition, high concentrations of TBT in subsurface sediments between the RM 6.5E SDU and Swan Island Lagoon (between RM 7 and 8) fall outside of any SDU. We request that EPA expand SDUs to include these areas, as well as other areas with high concentrations of non-focused COCs.

Our above analysis is based on areas of relatively high non-focused COC concentrations. We recommend that the contaminant intervals be expressed as multiples of the PRG or that EPA include a risk-based threshold in the legend for each of the COCs (most likely, the corresponding PRG) to enable a more meaningful evaluation of COC concentrations.

#### **EPA Response**

EPA has selected Alternative F with modifications as the final remedy. See Sections 2.1, 2.3, 2.6, and 2.31 of this responsiveness summary.

### **3.1.33 Limit Use of MNR – Especially in RM 6NAV SDU**

#### **Comment**

EPA assumes that MNR will be applied to all areas within the Site boundary that are not otherwise actively remediated. The Five Tribes assert that MNR will only be effective in areas that are predominantly depositional, not erosional. EPA's analysis of the natural recovery potential of each SDU indicates that all but two SDUs are considered "neutral," that is, neither consistently depositional nor erosional (USEPA 2016b, Section 3.6.1.2). The other two SDUs (RM 6NAV and RM 11E) are erosional. The results of this analysis do not provide confidence that natural recovery will be effective in any of the SDUs. Further, it is clear from many of the figures in the Figure D8 series of Appendix D of the feasibility study report that most SDUs contain at least some erosional areas. The summary analysis (compilation of results across all relevant data types) is conducted on SDUs only (USEPA 2016b, Table D8-3), so the natural recovery potential for areas outside the SDUs must be visually evaluated based on Figures D8-1 through D8-7. However, the areas outside of SDUs seem to have similarly mixed results.

We are particularly concerned about the RM 6NAV SDU, which EPA acknowledges is not conducive to natural recovery but which is primarily slated for MNR under Alternative I. We understand that any area in this SDU that is not dredged under the remedy may be navigational dredged (because it is in the navigation channel), which may remove material whose concentrations are above PRGs but below RALs. However, we are not convinced that navigational dredging will occur in a timeframe relevant to our requested recovery period of 10 years post-construction. We urge EPA to assign ENR to any area within this SDU that is not otherwise actively remediated if navigational dredging is not expected to occur within a period of 10 years post-construction, and if the navigational dredging is not expected to

be implemented throughout the entire MNR area of the SDU. Further, although a significantly lower percentage of RM 11E is slated for MNR under Alternative I compared to RM 6NAV, ENR, rather than MNR, should be assigned to any areas in this SDU not assigned to dredging or capping because this SDU is also erosional, and is not primarily in the navigation channel.

Therefore, EPA's finding that the entire river is at best neutral with regard to the potential for natural recovery highlights the need to select a remedy that is focused on active remediation and minimizes reliance on natural recovery.

### **EPA Response**

EPA recognizes the uncertainty associated with MNR, and that no model can predict with certainty how MNR will work in a dynamic and complex river system. Therefore, EPA chose to reduce reliance on MNR in the interest of reducing risks with technologies that are certain to work and in a shorter timeframe, and to focus greatly on the development of a robust monitoring plan following the ROD to evaluate achievement of cleanup levels with empirical data. The SEDCAM modeling results show that the selected remedy, Alternative F Modified, is protective within a reasonable timeframe given the model uncertainty. See also Sections 2.16, 2.31, 3.1.2, and 3.1.27 of this responsiveness summary.

### **3.1.34 Select Removal Over Capping where Feasible**

#### **Comment**

As stated previously, we urge EPA to select removal over capping whenever feasible, and especially when NAPL or NRC PTW is present. We are skeptical about the effectiveness of EPA's proposed significantly augmented reactive caps in containing these materials. At which sites has this technique been used to successfully contain these materials? For instance, the feasibility study report references the use of an organoclay reactive cap at the McCormick and Baxter cap but does not discuss the success of this cap (USEPA 2016b, p. 3-5). EPA indicates that reactive caps may not be effective when multiple contaminants (e.g., metals and organics) are present (EPA 2016b, Table 2.4-2). How does EPA plan to assess and manage this issue? We also point out that reactive caps need to be periodically replaced, as their sorptive or chemically reactive treatment capabilities degrade over time (USEPA 2016b, Table 2.4-2). We are concerned about the environmental impacts of replacing a cap over NAPL or NRC PTW. These concerns underscore the importance of removing NAPL or NRC PTW by all available means. We also point out that EPA describes the use of activated carbon for in-situ treatment as "permanent and irreversible as long as there is sufficient quantity of activated carbon to address the amount of contamination present" (USEPA 2016b, p. 4-33). Based on Table 2.4-2, it appears that EPA expects that activated carbon will need to be periodically replaced. EPA should clarify its expectation regarding the permanence of activated carbon and the need to replace it over time.

### **EPA Response**

Refer to Sections 2.5, 2.6, 2.13, 2.16, and 2.19 of this responsiveness summary.

### **3.1.35 Explore Removing Wharfs and Shore-Based Facilities**

#### **Comment**

EPA assumes that structures servicing active wharfs or shore-based facilities will remain intact during remedial activities (e.g., EPA 2016a, p. 36; EPA 2016b, p. 3-10). In contrast, we contend that EPA should seriously explore removing all such structures in active remediation areas to the extent practicable, particularly if they impede the removal of NRC PTW or NAPL. Perhaps there are major active structures whose removal is not possible. However, it may be feasible to remove minor active

structures to allow for the dredging of highly contaminated material from the Willamette River and to avoid capping such material.

### **EPA Response**

EPA agrees that maintaining flexibility in construction through the remedial design phase is an important consideration, particularly for nearshore areas near structures as well as area with debris. Decision matrices in the feasibility study report (USEPA 2016b) were developed as a method to guide the assignment of capping and dredging technologies, based on specific site characteristics within SMAs to evaluate the alternatives on consistent and transparent assumptions. A more flexible decision tree is included in the ROD and will be used during remedial design to define what actions should be taken in different areas of the Site based on the most recent design data. Once the data and river factors are evaluated within the context of the decision tree, a final design for construction can be completed. This design will then dictate the remedial construction. The decision tree is intended to provide clear direction on what actions should be taken under the different environmental conditions. See also Section 2.21 of this responsiveness summary.

### **3.1.36 Address Other Relevant Cap Types for PTW Remediation**

#### **Comment**

For many reasons, including implementability, short-term impacts, and cost, EPA does not typically consider removing operating structures such as wharves and piers unless the cleanup cannot be done effectively without removal. However, the selected remedy seeks to address all PTW at the Site through either capping or dredging. It is not currently clear why Section 3.2.2 of the feasibility study (“Technologies Applied to PTW Areas”) contains a sub-section describing containment technologies, but only describes significantly augmented reactive caps. We question why other relevant cap types used for addressing PTW are not also described in this section (e.g., reactive armored caps). Similarly, removal of PTW is not described in this section despite the fact that areas of PTW are subject to dredging. These omissions become confusing later in the document when these other technology types are applied to areas with PTW (e.g., EPA 2016b, Section 3.8.1), but their application to PTW is not described when the technology is originally presented (e.g., EPA 2016b, Section 3.4.7.4). These omissions compound our confusion when reviewing the technology assignment flowcharts. We suggest including descriptions of all technologies applied to PTW areas in Section 3.2.2 with a table to summarize when these technologies are used in each area (shallow, intermediate, river bank, and navigation channel/future maintenance dredge [FMD] regions) once the different regions are described.

#### **EPA Response**

Appendix D (Supporting Information for Alternative Development Feasibility Study) of the feasibility study report (USEPA 2016b) describes a set of generic cap designs that could be applied based on site-specific conditions, including the need for reactive materials to contain PTW and armoring to prevent erosion of the cap material. Remedial design sampling data will be used to apply the decision tree in the ROD and to inform the design in specific areas. Refer also to Section 2.5 of this responsiveness summary.

### **3.1.37 Use a Biologically Active Zone of 8 Rather than 4 Inches**

#### **Comment**

EPA assumes a minimum thickness of 12 inches for the physical isolation layer of caps (EPA 2016b, p. D-15). This thickness is based on a maximum burrowing depth of 4 inches. (The 12 inches is

calculated based on the sum of the 4-inch burrowing depth [i.e., the biologically active zone], a 2-inch buffer, and an additional 6-inch layer to increase the travel time of dissolved contaminants.) The BERA (Windward 2013) defines the biologically active zone of the riverbed as the top 20 cm (about 8 inches), not 4 inches. Further, lamprey ammocoetes (a species of cultural significance to the Five Tribes) burrow up to 6 inches (Liedtke et al. 2015) and may have the ability to burrow up to 8 inches (T. Whitesel, personal communication, February 9, 2016). We thus support using a biologically active zone of 8 inches instead of 4 inches. We ask EPA to evaluate whether the physical isolation layer would need to be increased accordingly or whether the 12 inches would be sufficiently thick to protect lamprey ammocoetes and other burrowing organisms.

### **EPA Response**

For the purpose of the feasibility study, a set of generic cap designs was developed to be applied based on site-specific conditions, including the need for reactive materials to contain PTW and armoring to prevent erosion of the cap material. To facilitate consistent application of capping technologies, all caps were assumed to be 36-inch thick and comprised of various combinations of sand, beach mix, activated carbon, organoclay, and armor stone. The precise composition and thickness of sediment caps will be determined during remedial design.

### **3.1.38 Consider Sandy Material with Higher Organic Content**

#### **Comment**

Feasibility study report Section 3 refers frequently to sand caps and layers of sand placed either post-dredging or to accomplish ENR (e.g., EPA 2016b, p. 3-32). We encourage EPA to consider not just pure sand but sandy material with higher organic content. Silts and clays and associated organic matter in sandy material can greatly improve the filtering and sorptive capacity of the cap. Use of a more mixed sediment cap also has the potential to be a better match to the ambient river bottom and may therefore more quickly become ecologically compatible. We suggest using a more inclusive term like “predominantly sandy sediment” or “sandy material.”

### **EPA Response**

The precise composition and thickness of sediment caps will be determined during remedial design in accordance with the ROD decision tree and design requirements.

### **3.1.39 Address Concerns with Thin Layer Placement**

#### **Comment**

The Five Tribes have persisting concerns about thin layer placement in the navigation channel/FMD region. The feasibility study states that “SMAs within the federally authorized navigation channel or designated as FMD are assigned dredging as a technology due to minimum water depth requirements, the placement of thin sand layers, in-situ treatment amendments, and conventional or reactive caps because stand-alone technologies above the established navigation dredge depth are considered incompatible with current and future waterway uses” and goes on to say, “Even in the case of dredging, navigation and maintenance dredge depth requirements will need to be considered during the design and implementation of dredging activities and the placement of any thin layer covers for managing residuals” (EPA 2016b, p. 3-10).

The first sentence is poorly structured and confusing regarding whether EPA considers thin sand layers, in-situ treatment amendments, and conventional or reactive caps all to be incompatible with current and future waterway uses. Although caps are often considered incompatible with navigation

channel/FMD regions, the latter sentence appears to include thin layer covers in remedial action for that zone. It is our understanding that a 12-inch sand cover will be applied to all dredging areas, including the navigation channel and FMD areas (EPA 2016b, p. 3-23). We request that EPA clarify this apparent discrepancy (i.e., between p. 3-10 and p. 3-23). This is an important issue, since dredging will be applied to significant stretches of these areas. The Five Tribes believe that thin-layer sand covers would be effective in managing residuals in these areas and thus would be appropriate; this is especially true if navigational dredging is not anticipated for many years.

#### **EPA Response**

In general, ENR is not planned for the navigation channel, but primarily as a residual management approach. Specific information associated with cap material, thickness of caps and/or types of cap layers are assumptions for the purposes of evaluating alternatives according to CERCLA criteria and developing cost estimates for the remedial alternatives. These assumptions were developed based on the existing data and will be finalized during the remedial design, after design level data to refine the baseline conditions are obtained.

If caps are used, the final depth would need to conform with planned and future navigation channel depths. See also Section 2.13.1 of this responsiveness summary.

### **3.1.40 Explain USACE Role in Dredging at the Site**

#### **Comment**

It is our understanding that EPA is considering giving the U.S. Army Corps of Engineers (the Corps) the authority to conduct remedial dredging in the navigation channel. The Corps would pay for the dredging (through Congressional appropriations), and the responsible parties would pay for disposal of the material. If EPA adopts this approach, we urge EPA to ensure that the Corps is following all precautions, BMPs, and any other requirements the responsible parties would be required to implement.

It is also our understanding that the Corps will at some point conduct navigational dredging at the Site. Will this only occur after construction of the remedy, or might it occur concurrently with remedy construction (i.e., in MNR areas)? It is important that navigational dredging not interfere with the remedy, either by slowing down the remedy or by causing undue resuspension of contaminated sediment or recontamination.

#### **EPA Response**

EPA is selecting the final remedial action needed to address unacceptable risks present due to the contamination found at the Site. After the ROD is issued, EPA intends to seek performance of the remedy by identified PRPs. At this time, there has been no agreement that the Army Corps of Engineers will implement any part of the ROD as part of its navigation dredging.

EPA and the Corps have a Letter of Agreement on coordinating Corps dredge projects with EPA cleanup program. We anticipate continuing to work with the Corps under that agreement post-ROD. However, with the final ROD issued, EPA anticipates that future maintenance dredging within the Site will be evaluated consistent with the final ROD and cleanup levels for purposes of evaluating both what contaminant concentrations may be exposed by the dredging or maintenance activity, requiring BMPs during and after work is completed, and making decisions regarding where the dredged sediment can be disposed.

Various BMPs will be evaluated on location specific basis during remedial design, given the variability of conditions within the harbor. Details regarding sediment dispersion control and location-specific engineered rigid control measures will be determined during remedial design. Schedule of future maintenance dredging within the navigational channel will be coordinated during the remedy implementation.

### 3.1.41 Consider All Aspects of Using a CDF

#### Comment

We are open to the idea of constructing a confined disposal facility (CDF) to contain contaminated sediments on-site. Many of our concerns about capping, described above, also apply to CDFs. On balance, however, we feel that a CDF could be an appropriate, cost-effective solution for the disposal of large quantities of contaminated sediment. A CDF would greatly reduce risks and community disturbances related to transporting contaminated material to a landfill. In order for the Five Tribes to fully support a CDF, however, a number of criteria would need to be satisfied, as outlined in Table 3.4-7 of the feasibility study report and Table 8-1 of the CDF Design Analysis Report (Port of Portland 2011). The CDF must be designed to safely contain material in perpetuity, withstand a Cascadia Subduction Zone event, and be protective of human health and the environment. The design must include the best available technology (e.g., treating dredged sediment during placement) to enhance the performance of the CDF and prevent groundwater or effluent discharge from re-contaminating the river. Funds must be committed to monitor and maintain the CDF in perpetuity. The monitoring program must be comprehensive and detailed in the ROD, including but not limited to detailed emergency management and contingency plans. Material deposited in the CDF must meet rigorous standards: for instance, it must meet the substantive requirements of the 404(b)(1) guidelines under the Clean Water Act, must not be Resource Conservation and Recovery Act or state hazardous waste, and must be shown to be capable of being contained. ICs must be sufficient to protect the integrity of the CDF and prevent exposure to humans and the environment. There also must be measures in place to enforce the ICs.

In summary, although the Five Tribes prefer complete removal of contaminated sediments off-site, we could potentially support an upland CDF, if and only if the result on balance would be a more protective, permanent remedy (e.g., higher volume of sediment removal) and rigorous standards are fully met for its design, construction, operation, maintenance, and monitoring in perpetuity.

None of this section applies to a confined aquatic disposal (CAD) cell, which the Five Tribes would oppose in any instance. It is our understanding that the hydrology of the vast majority of the Site is too dynamic to safely contain subaqueous contaminated material. As noted in feasibility study Table 2.4-3, CAD cells have not been demonstrated to be capable of safely containing contaminated material at the Site in the long term. The design of a potential CAD cell has not been sufficiently advanced to demonstrate that implementation is feasible. Key types of modeling to support an evaluation of long-term effectiveness, such as contaminant migration, were not performed. Hydrologic and hydraulic modeling to address flood rise and flood storage also was not performed. Further, an evaluation of short-term impacts has not been conducted.

#### EPA Response

Refer to Section 2.14.1 of this responsiveness summary.

### 3.1.42 Enact Protective Advisories Quickly

#### Comment

EPA acknowledges that the current fish consumption advisories may not be sufficiently protective of all populations (EPA 2016b, p. 4-15). We agree that existing advisories are not adequately protective. We urge EPA to enact protective advisories as quickly as possible after the ROD is signed. These advisories should be based on existing data and can be revised if warranted based on data collected during remedial design.

#### EPA Response

Refer to Sections 2.3.2 and 4.14 of this responsiveness summary.

### 3.1.43 Reduce Contaminant Inputs to the Site

#### Comment

EPA asserts that the preferred alternative will achieve PRGs 23 years following construction (EPA 2016c). EPA estimates that at that time, at which point the Site will presumably be de-listed, safe fish consumption will be limited to 160 fish meals per 10 years (based on a non-cancer hazard of one). This fish consumption rate is significantly lower than the tribal consumption rate for resident fish that is used in the BHHRA (Kennedy/Jenks 2013) (1,380 resident fish meals per 10 years<sup>2</sup>). The Five Tribes find this discrepancy to be wholly unacceptable. We urge EPA to apply all available means to reduce contaminant inputs to the Site (e.g., from upstream, upland, and aerial sources) so that rates of safe fish consumption may be further increased in the future.

#### EPA Response

Refer to Sections 2.3.2, 2.3.3, 2.27.1, and 4.1.10 of this responsiveness summary. EPA recognizes that the remedy likely will not reduce the concentrations of PCBs and other contaminants to levels low enough to allow for consumption at the higher consumption rates associated with subsistence fishing. The scope of the CERCLA action is restricted to approximately 10 miles of the Willamette River, but upstream of the Site, background levels of PCBs from “clean” areas exceed the acceptable range based on conservative risk estimates, meaning that even with a more stringent remedy proposed. Fish advisories would likely remain in effect following the cleanup. However, these advisories are expected to be less restrictive under the selected remedy because the highest concentrations of bioaccumulative contaminants in sediment would be removed or capped such that they no longer enter the food chain within the Site. Watershed-wide implementation of source reductions through water quality programs by the DEQ in conjunction with source control activities at the Site are expected to contribute to the elimination of fish consumption advisories under EPA’s ROD. Although CERCLA-related fish advisories would remain in place until cleanup levels are achieved, Oregon Health Authority may still impose an advisory based on broader watershed risks.

In response to this comment, background fish tissue concentrations were estimated for total PCBs using the Food Web Model and background sediment (9 µg/kg) and surface water concentrations (0.023 nanograms per liter). Allowable fish meals per month were then estimated for a range of exposure scenarios and risk ranges. Based on this calculation, the allowable fish meals/month would range from 0.08 to 14.2, or approximately 1 to 170 (8-ounce) fish meals per year. The allowable fish meals for an adult at the  $1 \times 10^{-5}$  risk level is 17 (8-ounce) meals per year. For comparison, adult exposure scenarios evaluated in the baseline human health risk assessment ranged from 28 up to 282 (8-ounce) fish meals per year, based on the tribal fish consumption rate of 175 grams per day.

### 3.1.44 Clarify Authority for Fish Consumption Advisories

#### Comment

We are unsure which entity will have authority to issue fish consumption advisories during the remedy (i.e., EPA or Oregon Health Authority [OHA]). If OHA will be the responsible agency, then EPA should provide OHA adequate funding (e.g., through a Cooperative Agreement) to implement the advisories and collect Site-specific data on fish tissue contaminant concentrations.

#### EPA Response

See Sections 2.3.2, 2.17.2, 2.17.3, and 4.1.14 of this responsiveness summary.

### 3.1.45 Ensure Fish Consumption Advisories Are Protective of All Groups

#### Comment

We request that fish consumption advisories be developed that are protective of all segments of the fishing community, including tribal fishers, and that the BHHRA (Kennedy/Jenks 2013) assumptions be used to develop the fish consumption advisories. This will require consumption advisories to be developed for multiple segments of the population, including nursing mothers, children, and other adults, as well as for consumption of fillets and whole-body fish. We also request that consumption advisories be developed based on the cumulative risk of all Site COCs, not just focused COCs.

#### EPA Response

See Sections 2.3.2, 2.17.2, 2.17.3, and 4.1.14 of this responsiveness summary.

### 3.1.46 Set Post-Cleanup Fish Consumption Advisories Using Pre-Cleanup Methods

#### Comment

As noted above, fish consumption advisories are expected to be needed after the Site is de-listed. Would OHA have authority for issuing and enforcing these fish consumption advisories? If so, we request that the fish consumption advisories be developed using the same methodology that will be used to set fish consumption advisories before the Site is de-listed (see our recommendations above). OHA's methodology for developing the current fish consumption advisories appears to be inadequate for protecting fish consumers.

#### EPA Response

See Sections 2.3.2, 2.17.2, 2.17.3, and 4.14 of this responsiveness summary.

### 3.1.47 Consider Migratory Fish Consumption Restrictions

#### Comment

Although EPA does not indicate that restrictions for consumption of migratory fish are currently necessary nor will be needed in the future, we urge EPA to thoroughly monitor contaminant concentrations in the tissue of migratory fish to determine whether fish consumption advisories for migratory fish are needed. Of specific concern to the Five Tribes, lamprey ammocoetes spend three to seven years burrowed in Site sediment and therefore are likely exposed to more Site contamination than other migratory fish like salmon, who spend only one to three years in freshwater before going to sea and who are not known to spend extended periods directly exposed to Site sediment.

#### EPA Response

See Sections 2.3.2, 2.17.2, 2.17.3, and 4.14 of this responsiveness summary.

### 3.1.48 Provide Assumptions for Use of Fish Consumption Advisories

#### Comment

The proposed plan outlines expected fish consumption advisories during construction (EPA 2016c, p. 58), but the underlying assumptions for those calculations do not appear to be described in either the proposed plan or the feasibility study report. For example, did EPA calculate expected water column concentrations during construction due to resuspension of contaminants and then model concentrations in fish tissue based on those water column concentrations? Do the recommended fish meal limits represent fillet or whole body consumption?

#### EPA Response

EPA did not calculate or model fish tissue concentrations based on water column concentration during remedy implementation. The fish tissue concentration was addressed in a more qualitatively way in the proposed plan (USEPA 2016c).

The recommended fish meal limits represent fillet consumption. Refer to EPA's memorandum, *Formal Dispute on the EPA Notice of Non-Compliance and Directed Revisions to the Portland Harbor BHHRA (Kennedy/Jenks 2013) and Request for Dispute Resolution; Administrative Settlement Agreement and Order on Consent for Remedial Investigation/Feasibility Study, USEPA Docket No. CERCLA-10-2001-0240-Final Resolution* dated December 6, 2012.

For further response on the assumptions on fish consumption/tissue concentration see EPA response to LWG Dispute Response 1r (Appendix A of this document) and Sections 2.33 and 2.34 of this responsiveness summary.

### 3.1.49 Revisit Strategies for Fish Consumption Advisory Signage

#### Comment

The current fish consumption advisory signage at the Site has been inadequate to date. We request that the Site be well-signed and that regular inspection and maintenance of those signs occur. Furthermore, surveys of fishers should be conducted with each five-year review to determine the effectiveness of the fish consumption advisories. We urge EPA to consider culturally appropriate outreach strategies in addition to signage.

#### EPA Response

See Sections 2.3.2, 2.17.2, 2.17.3, 2.28, and 4.1.14 of this responsiveness summary.

### 3.1.50 Get Input on Whether ICs in Regulated Navigation Areas Will Be Burdensome

#### Comment

feasibility study Section 3.4.7.7 (EPA 2016b, p. 3-21) describes some of the ICs that will be needed on both a short-term and long-term basis after the remedy has been constructed. One such IC is waterway use restrictions, or regulated navigation areas (RNAs), which aim to ensure that the integrity of caps is maintained by prohibiting activities such as the anchoring of vessels. The area requiring RNAs for the Site will likely be orders of magnitude greater than the existing RNAs in the vicinity. The Five Tribes are unsure about the extent to which the RNAs would affect vessel operation. It is our goal to see an environmentally protective remedy chosen for the Site that will not significantly affect (i.e., restrict) human use of the river in perpetuity. We request that the Corps and other relevant parties be consulted to determine whether RNAs in the identified capping locations will be

burdensome. We would prefer their input as early in the process as possible. If RNAs would be burdensome, we urge EPA to remove contaminated material in order to avoid the need for RNAs associated with capping.

**EPA Response**

Refer to Sections 2.28 and 4.1.5 of this responsiveness summary.

**3.1.51 Develop an ICs Implementation and Assurance Plan****Comment**

The Five Tribes request that an Institutional Control Implementation and Assurance Plan be developed during remedial design. The development of this plan should be referenced in the ROD

**EPA Response**

See Sections 2.28 and 3.2.21 of this responsiveness summary.

**3.1.52 Specify Frequency of Monitoring to Ensure ICs Are Effective****Comment**

Monitoring of the effectiveness of ICs is critical to the success of the remedy. Certain ICs will need to be monitored, at a sufficient frequency and in perpetuity, including RNAs and land use/access restrictions. The ROD should specify the frequency of these types of monitoring, as well as actions that EPA will consider if the ICs are shown to be ineffective.

**EPA Response**

See Sections 2.28 and 3.2.21 of this responsiveness summary.

**3.1.53 Ensure Flexibility in Implementation of Remedy****Comment**

LWG has expressed concern that EPA's technology assignment approach is not nuanced enough. For instance, LWG seems concerned that remedial design data will indicate that dredging in a designated dredge area is not technically feasible, and another active remediation technology must be employed (e.g., a small area is too close to a major structure to be dredged to the required depth, or slope failure is predicted due to deep dredging depths in a confined area). It is our understanding, based on conversations with EPA, that if the ROD requires an area be dredged, the responsible parties do not have the flexibility to cap that area (i.e., if it entails a deviation from the technology assignment approach). A decision to cap in an area previously designated as dredge would require a ROD amendment. More broadly, if a point of flexibility is not specified in the ROD, it is not a flexibility that the responsible parties can exercise during remedial design in the absence of a ROD amendment. We generally support this approach and believe it is important for all interested parties to understand what the ROD does and does not allow. Transparency is essential.

**EPA Response**

See Section 2.24. EPA acknowledges that technology assignments will be evaluated based on new data and observations collected during remedial design. The ROD contains a revised, simplified flow chart for selection of remedial technologies during the remedial design process. The ROD decision tree indicates more clearly the flexibility for selection of remedial technologies with the assumption that a detailed evaluation of area-specific conditions would be conducted during remedial design. Remedial design investigations will consider prioritization of areas posing highest risk, sequencing, and other

aspects of how the remedial action will be implemented. Avoiding disturbance or recontamination of early action areas will be an important part of the remedial design evaluations. Construction of permanent caps will be carefully scheduled to avoid recontamination from upland or in-river work.

EPA is aware that area-specific conditions must be considered during remedial design, including the presence of active docks or other structures, caps and other remedial activities already in place, river uses, and many other considerations. Additional guidelines are provided in the ROD to convey this information.

The feasibility study states in several places that additional data will be collected during remedial design to assist in refining the remedy beyond the feasibility study-level of analysis and the ROD reflects this as well. EPA intends to evaluate additional data during remedial design to refine the following: delineation of contamination, selection and design of remedial technologies and construction methods, projections of natural recovery, treatment and disposal requirements, measures for aquatic and listed species protection, and compensatory mitigation requirements, to name a few.

### 3.1.54 Be Flexible in Remedy Implementation

#### Comment

We do consider it a possibility that remedial design data may indicate that an assigned technology is not feasible to employ at a particular location. Lacking in the proposed plan and feasibility study report is a description of how flexibility during remedial design would be granted, if at all, or how MOU partners would be involved. We request clarification in the ROD that MOU partners will be consulted when EPA is considering granting deviations from the selected remedy. The Five Tribes are generally in favor of responsible parties dredging in areas designated for capping (e.g., if they would like to avoid monitoring/maintenance costs for a cap), such as if material is under a structure that the responsible parties can remove. Conversely, the rationale for capping instead of dredging would need to be compelling to gain our support.

An example of where a small degree of flexibility may be needed is at the border of the shallow and intermediate regions in some cases. We understand that intermediate regions may be dredged to depths of up to 15 feet below the current mudline. The bathymetry of the adjacent shallow areas will be maintained. Therefore, there may be a significant difference in depth between these two adjacent areas. We are concerned about cap stability in shallow areas that are adjacent to areas up to 15 feet deeper. Even with an adequately shallow side slope, sloughing may occur, compromising the stability of the cap. EPA's assumptions are sufficient for feasibility study purposes; EPA likely intends to address this concern in remedial design. However, this example does raise the question of the degree to which EPA will grant the responsible parties flexibility during remedial design (e.g., deviations from the exact technology footprints resulting from a combination of sediment contamination data, RALs, and the technology assignment flowcharts). The Five Tribes expect to be involved in any considerations of deviations from the selected remedy.

#### EPA Response

During remedial design, debris and other area-specific features will be evaluated. The decision tree in the ROD has been revised to clearly outline this process. Also, EPA agrees that maintaining flexibility in construction methods through the remedial design phase is an important consideration, particularly for nearshore areas near structures and area with debris. Also see Section 3.1.53 of this responsiveness summary.

### 3.1.55 Engage MOU Partners in Evaluating Sampling Plans

#### Comment

We understand that new data will be collected during remedial design, and the result of these new data may be that the SMAs change in area. We do not consider this to be a deviation from the ROD or a flexibility. We do, however, request that EPA engage MOU partners in the evaluation of proposed sampling plans to collect new data, data quality assessments, and the use of new data, such as whether the new data should replace the old data (e.g., as evidence of recovery) or merely be added to it (e.g., due to the heterogeneous nature of the system).

#### EPA Response

Throughout the remedial investigation/feasibility study process, EPA fostered meaningful engagement with the MOU partner tribes and encouraged and facilitated Tribal involvement, including conducting formal Tribal consultations. EPA will continue this working relationship with the MOU partner tribes to ensure that tribal concerns and interests are considered.

### 3.1.56 Reevaluate Deposition Scoring

#### Comment

The deposition section of feasibility study Section 3.4.6.1 states that areas were evaluated using two lines of evidence: the difference in elevations between bathymetric surveys and the ratio of surface to subsurface sediment concentrations (EPA 2016b, p. 3-14). Figure 3.4-16 implies that only one of these criteria must be satisfied to consider an area depositional, as opposed to both needing to be satisfied. It also implies that a cell would only receive one score for the depositional category, not one score for each of the deposition lines of evidence. We instead request that either: (1) the two lines of evidence each receive their own score or (2) in order to receive a depositional designation, both lines of evidence must be satisfied. EPA's methods regarding the above points need to be clearly stated in the text.

#### EPA Response

See Section 2.26 of this responsiveness summary and LSS Dispute Issue 14 (Appendix A of this document).

### 3.1.57 Modify Deposition Area Scoring

#### Comment

In depositional areas, we think it would be most appropriate to assign a 0 rather than 1 to dredging since deposition is not an impediment to dredging. A depositional area may necessitate more dredging than a non-depositional area, but this possibility does not limit the application of this technology.

#### EPA Response

See Section 2.26 of this responsiveness summary and LSS Dispute Issue 14 (Appendix A of this document).

### 3.1.58 Change Preference for Capping When Scores Are Equal to Dredging

#### Comment

The feasibility study report states that "When dredging and capping score equally, capping is selected due to the lower initial capital cost." (EPA 2016b, p. 3-17). The Five Tribes disagree with this decision rule. As stated above, we have a strong preference for the removal of contaminated material. Further, the above quotation implies that EPA selects capping over dredging because it is more cost-effective.

We point out that capping generates long-term costs associated with monitoring, maintenance, and oversight of the caps. Because caps must be maintained in perpetuity, these costs may be significant and eventually eclipse the larger initial capital cost of dredging, in non-discounted terms. Without an understanding of the frequency of instances when dredging and capping are scored equally and the overall effect on the technology assignments due to this decision rule, we are in favor of selecting dredging, rather than capping, in the event of a tie.

#### **EPA Response**

See Section 2.26 of this responsiveness summary and LSS Dispute Issue 14 (Appendix A of this document).

### **3.1.59 Reconsider Applicability of Capping in Troublesome Areas**

#### **Comment**

The matrix currently assigns a score of 1 to armored cap and cap categories in the presence of rock, cobble, or bedrock, and structures or pilings. The Five Tribes do not believe that these conditions favor these technologies. Rather, we believe that they neither favor nor limit the technologies. Thus, we feel these conditions merit a score of 0 for these technologies.

#### **EPA Response**

See Section 2.26 of this responsiveness summary and LSS Dispute Issue 14 (Appendix A of this document).

### **3.1.60 Address Inconsistencies in Technology Assignment Flowcharts**

#### **Comment**

In general, we find the technology assignment flowcharts to be confusing since the text of the feasibility study does not always match what is presented in the figures. We provide two examples of these inconsistencies, though additional inconsistencies exist. First, the text of the feasibility study states that for river banks, “if NAPL or PTW that is not reliably contained is present, a reactive armored cap is assumed” (EPA 2016b, p. ES-9). However, Figure 3.8-1d does not show the use of a reactive armored cap. Instead, options include excavation with a significantly augmented reactive cap and excavation with an engineered cap. A second example is dredging in the shallow region. The feasibility study states that “the shallow region is assigned dredging with backfilling or capping after dredging to remove or contain contamination while maintaining water depths” (EPA 2016b, p. 3-11). However, Figure 3.8-1c does not specify that dredging will occur for NAPL or NRC PTW that is under a structure, despite the fact that a significantly augmented reactive cap with armor stone is the assigned technology. This problem exists for other cap types in the flowchart as well (e.g., reactive armored cap and armored cap) even though many technology descriptions do specify that dredging will occur. We understand that dredging is difficult under structures, but EPA has also stated its intention to maintain existing bathymetry in shallow areas. It is unclear which source, the feasibility study text or the figure, accurately reflects EPA’s intentions. To reduce confusion, we strongly suggest ensuring that the text of the feasibility study and the technology assignment flowcharts are consistent. We support the use of significantly augmented reactive caps on river banks where NAPL or NRC PTW is present. We also support dredging before capping in the shallow and intermediate zones when NAPL or NRC PTW is present.

#### **EPA Response**

See Section 2.26 of this responsiveness summary and LSS Dispute Issue 14 (Appendix A of this document).

### 3.1.61 Use Capping Consistent Nomenclature

#### Comment

Related to the above comment, the term “reactive armored cap” is used consistently in the feasibility study, but the section where that type of cap is described is titled “armored reactive cap.” We suggest using consistent nomenclature to avoid confusion.

#### EPA Response

Comment noted.

### 3.1.62 Remove as Much PTW and NAPL as Possible

#### Comment

As noted above, we strongly urge EPA to remove NAPL and NRC PTW if at all possible. Any structures impeding dredging of these materials should be seriously evaluated for the feasibility of removal. In line with our preference for removal of these structures, we suggest an additional decision point for NAPL and NRC PTW that are under a structure in shallow and intermediate regions (EPA 2016b, Figures 3.8-1c and 3.8-1b). This decision point should be “Can structure be removed?” A “Y” answer would lead to dredging rather than (or in addition to) a significantly augmented reactive cap. The Five Tribes expect to be involved in decisions regarding whether individual structures can be removed.

#### EPA Response

See Sections 2.5, and 3.1.53 of this responsiveness summary.

### 3.1.63 Apply Higher Standard for Deciding to Leave a Structure in Place

#### Comment

Similarly, for highly toxic PTW that is under a structure (in the intermediate and shallow areas), we support adding a decision point that asks “Can structure be removed?” A “Y” answer would lead to dredging. Because we prioritize removal of NAPL and NRC PTW that are under structures compared to highly toxic PTW under structures, we would support EPA applying a higher standard for leaving a structure in place for NAPL and NRC PTW compared to highly toxic PTW (i.e., EPA should go to greater lengths to remove structures prohibiting the removal of NAPL and NRC PTW compared to highly toxic PTW).

#### EPA Response

See Sections 2.5, and 3.1.53 of this responsiveness summary.

### 3.1.64 Address Lateral Migration under Caps

#### Comment

According to the shallow zone flowchart, if NAPL or NRC PTW is not under a structure and is at a depth of greater than 15 feet, then a reactive cap, rather than a reactive residual layer, would be used at the bottom of the dredge prism (also as described in EPA 2016b, p. 3-38). Although it seems less likely that the material would migrate vertically through a reactive cap and other material totaling 15 feet in thickness, we are concerned about lateral migration. How does EPA envision evaluating the potential for lateral migration during remedial design? The potential for lateral migration underscores the importance of removing NRC PTW if at all possible.

#### EPA Response

See Sections 2.5, and 3.1.53 of this responsiveness summary.

### 3.1.65 Minimize Capping in Shallow Areas where Possible

#### Comment

The shallow water flowchart indicates that, unless NAPL or NRC PTW is present, if the RAL concentrations are not expected to be reached within 5 feet of depth, the contaminated sediment will be dredged to 3 feet and replaced with an engineered cap + beach mix (also described in EPA 2016b, p. 3-38). The depth criterion in this analysis is an important decision point. Shallow areas provide important habitat and support numerous human uses; for these reasons, as well as reasons stated elsewhere in this document, the Five Tribes would like to minimize capping in shallow areas to the extent practicable. Figure 3.4-32h indicates that using the 5-foot criterion would leave substantial contamination in the river, especially for Alternatives E through G (EPA 2016b, Figures 3.4-32d through f). In contrast, using a 10-foot criterion would remove most of the shallow water contamination. We believe that the 10-foot criterion is more appropriate. However, we would consider supporting an intermediate depth, such as 7 feet, if the evidence showed that intermediate depth would be nearly as effective at removing contamination as the 10-foot criterion.

#### EPA Response

See Sections 2.5, 2.7, 2.26, and 3.1.53 of this responsiveness summary.

### 3.1.66 Address Intermediate Area Issues with Flowchart

#### Comment

The intermediate area flow chart indicates that an area originally assigned an engineered cap could be “demoted” to broadcast granulated activated carbon (GAC), ENR, or MNR (i.e., if the area is outside of RAL boundaries and outside of NAPL and NRC PTW areas; EPA 2016b, Figure 3.8-1b). We are concerned about an area originally assigned to capping being reassigned to a less protective technology. However, it is not clear which circumstances would lead to an original assignment of an engineered cap if the area was outside of RAL boundaries and neither NAPL nor NRC PTW was present. Is the “designated engineered cap” box in this section of the flowchart erroneous?

#### EPA Response

See Sections 2.5, 2.7, 2.26, and 3.1.53.

### 3.1.67 Incorporate the Same Decision Rule for Shallow Areas as Intermediate Areas

#### Comment

As illustrated in the intermediate area flowchart (EPA 2016b, Figure 3.8-1b), broadcast GAC is a meaningful change over MNR for reliably contained PTW through treatment using GAC that is outside of RAL boundaries. We support this assignment, but only if the area is depositional or neutral, not erosive. Similarly, MNR and ENR should only be applied in depositional and neutral areas. Dredging should generally be assigned to erosive areas. Additionally, we question why the shallow water flowchart does not illustrate this same set of decision rules related to highly toxic PTW outside of RAL boundaries (EPA 2016b, Figure 3.8-1c). We suggest incorporating this same decision rule for shallow areas.

#### EPA Response

See Sections 2.5, 2.7, 2.26, and 3.1.53 of this responsiveness summary.

### 3.1.68 Clarify Procedure if NAPL or NRC PTW Is Found at Depth

#### Comment

We assume that the following note on the navigation channel/FMD areas flowchart implies that EPA intends to remove all NAPL and NRC PTW in these areas: “All Concentrations greater than RAL alternative are less than 18 feet deep in the FMD and 15 feet in the Navigation Channel. The diagram is based on the assumption that no PTW or sediment concentrations are found below these depths” (EPA 2016b, Figure 3.8-1a). EPA should clearly state in the feasibility study text their intention to remove all NAPL and NRC PTW in these areas.

Additional sampling during remedial design may identify NAPL or NRC PTW below these previously-identified depths. If this proves to be the case, would the decision still be to dredge to the greater of the RAL depth or depth of PTW and then cover with a reactive residual layer, as indicated in the flowchart (EPA 2016b, Figure 3.8- 1a)? Or would this decision be invalidated based on EPA’s note that the diagram is based on the assumption that NAPL and NRC PTW are not found below 18 feet in the FMD area and 15 feet in the navigation channel? We strongly urge EPA to remove all NAPL and NRC PTW in the navigation channel/FMD areas no matter the depth of contamination. Capping is impractical in these areas due to the use restrictions that capping requires. EPA must clarify their intention regarding the possibility of NAPL or NRC PTW being found below the specified depths. It is our understanding that the flowcharts in Figures 3.8-1a through d will form the basis for the remedy. Thus, they should be able to be applied to any findings during remedial design and should not be invalidated based on remedial design data.

#### EPA Response

See Sections 2.5, 2.7, 2.26, and 3.1.53 of this responsiveness summary.

### 3.1.69 Revisit Background Levels as Cleanup Progresses

#### Comment

EPA has consistently maintained that background levels of some COCs are high and will prevent the remedy from achieving all of the remediation goals. We encourage EPA to continue to work with DEQ, so that DEQ may continue to investigate and control upriver sources under their state authority. Since remedial design and construction will take many years, a sustained state effort upriver may improve conditions over this timeframe and allow all PRGs to be met post-construction.

#### EPA Response

See Sections 2.5, 2.17.3, 2.27, and 4.1.10 of this responsiveness summary.

### 3.1.70 Explore Additional Options for Upgradient Sites

#### Comment

The Five Tribes are concerned that cleanup standards used for areas in the Site that were previously remediated (e.g., McCormick & Baxter) may not be as stringent as the cleanup alternatives outlined in the proposed plan. If they are not as stringent, we request that a risk analysis be conducted using monitoring data for these areas in order to determine whether these areas are sufficiently protective based on the currently proposed cleanup standards. If not, we suggest exploring additional remediation options for these areas.

#### EPA Response

See Section 2.32.2 of this responsiveness summary.

### 3.1.71 Address River Bank Active Remediation Questions

#### Comment

We are concerned that only 65 percent of contaminated river banks are currently identified for active remediation. How does this 65 percent intersect with DEQ's current and future work on river banks? Will DEQ continue to evaluate the 35 percent of contaminated river banks not currently slated for remediation and then remediate them if they pose a risk for recontaminating areas of in-river work (e.g., evidence of slope failures and unconsolidated material versus armored shoreline)? Has some portion of this 35 percent already been evaluated and/or remediated by DEQ? Will EPA have the authority to remediate additional river banks if they gain supporting evidence of their recontamination potential during remedial design? Further explanation is needed to address the above questions.

Further, EPA notes that while increasing the extent of capping, dredging, in-situ treatment, or ENR for the in-river portion of the Site would be easily implemented for each of the alternatives if they failed to be sufficiently protective, "[a]dditional remediation on river banks could be more problematic due to factors such as adjacent land use, structures, steepness, use of the adjacent waterways, and community concerns" (EPA 2016b, p. 4-39). We are unclear on why additional river bank remediation would be more challenging than other types of remediation. If this is indeed the case, our concerns about DEQ's role in additional river bank remediation and the timing of that work are more salient.

#### EPA Response

Alternative F Modified addresses 78 percent of the contaminated river bank, and DEQ will continue to evaluate river banks which might pose recontamination threats to the in water remedy. See Sections 2.6 and 2.26 of this responsiveness summary.

### 3.1.72 Remediate a Higher Percentage of the Groundwater Plume

#### Comment

We are similarly concerned that only 33 percent of known groundwater plume areas would be addressed (i.e., with a reactive cap or reactive residual layer) under Alternative I. Groundwater plume areas that are not addressed may continue to serve as a source of contamination to the river and may recontaminate the river post-remedy. Even assuming that DEQ will continue to remediate groundwater sources of contamination, there are likely to be instances where "a portion of the plume... has moved beyond the control point and continues to seep into the river" (EPA 2016b, p. 3-6). If these plumes fall outside of the 33 percent of plume areas that EPA will address, it seems likely that they will continue to recontaminate the river. What justification can EPA provide to demonstrate that treatment of only 33 percent of these areas will support a protective remedy? In the absence of additional information, we support remediation of a much higher percentage of groundwater plume areas.

#### EPA Response

Alternative F Modified addresses 39 percent of the river bottom impacted by groundwater plumes (as currently delineated) through construction (Figure 4.2-24 and Table 4.2-6); the remainder of the contaminated groundwater would be left to MNR and/or be more dependent on the adequacy of the source control at this time. See Sections 2.6 and 2.26 of this responsiveness summary.

### 3.1.73 Use a More Protective Remedy – Based on Benthic Risk

#### Comment

EPA defines the benthic risk area as the area exceeding RAO 5 PRGs. Feasibility study report Figure 4.2-29 maps the benthic risk area against Alternative I SMAs, illustrating that a small percentage of the benthic risk area is encompassed by SMAs (17 percent), but larger percentages of the areas defined as 10 or 100 times (10x or 100x) the RAO 5 PRGs are encompassed by the SMAs (64 percent and 87 percent, respectively; EPA 2016b, Table 4.2-7). Considering that the BERA (Windward 2013) benthic risk exceedance points are not well correlated with the 10x and 100x benthic risk areas (EPA 2016b, Figure 4.2-29), the percent of areas that are likely to pose a benthic risk (including the BERA points) that are encompassed by SMAs is considerably smaller than the values presented in Table 4.2-7. The poor correlation between the BERA benthic risk exceedance points and the 10x and 100x benthic risk areas, as well as high number of BERA points not actively remediated under Alternative I, support the need for a remedy that is more protective than Alternative I.

#### EPA Response

Alternative F Modified addresses 72 percent (10 x Benthic Risk) of the area with unacceptable benthic risks (ROD Table 12). See LWG Dispute Issue 1b (Appendix A of this document).

### 3.1.74 Address Issues with Beaches

#### Comment

Many questions persist around the concept of “beaches.” Does EPA define beaches as above the high tide line or some other water-based or vertical datum, and is this area outside of the scope of active remediation? If so, what is the relationship between beaches and river banks (i.e., are beaches a subset of river banks, sediments, or neither)? What would be the mechanism for risk reduction on beaches (e.g., river bank capping, upland source control, deposition of cleaner material from the remediated Willamette River sediment bed during high water events)? These points should be clarified in the ROD.

#### EPA Response

For the feasibility study evaluation, EPA used geomorphic or topographical data to define river bank region with contamination. The ROD defines the river bank region to extend to the top of the bank. River banks are included as part of the selected remedy. The ROD had been clarified that beaches within a SMA will be treated similarly as the Shallow Region in the ROD decision tree.

### 3.1.75 Consider Additional Strategies in the Green Remediation Plan

#### Comment

Regarding the Green Remediation Plan outline presented in Appendix M, the Five Tribes encourage EPA to not only review BMPs for each technology and process, but also to identify ways to decrease the carbon footprint of the remedy on a Site-wide scale. For example, evaluating ways to minimize total energy use and maximize use of renewable energy will likely be a more feasible and cost-effective option when evaluated on a Site-wide scale rather than by individual technology or process. We also encourage EPA to consider employing strategies such as opting for time-of-use or market-based electricity pricing plans. For example, costs may be driven down by operating treatment systems at a heavier load during nonpeak, lower-cost hours and constructing small-scale renewable energy systems to supply power directly to certain components of a treatment system. Annual energy costs for implementing a remedy are typically high, so managing energy requirements creatively may help in driving down those costs (EPA 2011).

**EPA Response**

Comment Noted. A green remediation plan will be prepared as part of the remedial design phase of the project for each action. The plan will discuss how impacts will be mitigated to the extent possible and as part of this analysis rail and barge transport of wastes will be discussed, and used wherever possible to limit greenhouse gas emissions and lessen neighborhood impacts for air toxics such as nitrous and sulfur oxides, consistent with EPA national and regional guidance. Where trucking cannot be avoided, the plan will discuss optimum haul routes to minimize diesel exhaust exposure to sensitive subpopulations (known to cause childhood asthma), such as residential streets near schools.

**3.1.76 Evaluate the Feasibility of an On-Site Transloading Facility****Comment**

We understand that there does not currently exist an on-site transfer (transloading) facility to transfer dredged material to trucks or rail for permanent disposal at an off-site landfill. In the absence of an on-site facility, the material would likely be shipped by barge to a transloading facility on the Columbia River, where it would then be transferred to an off-site disposal facility via truck or rail. The proposed plan states that if an on-site facility is constructed, the material is expected to be transloaded to an off-site disposal facility via rail, rather than via truck (EPA 2016a, p. 31). We encourage EPA to thoroughly evaluate the feasibility of an on-site facility and to carefully weigh the environmental risks and benefits of each approach. Shipping material to an off-site facility on the Columbia River runs the risk of spilling contaminated material into the Columbia River either during transit or during offloading. EPA should also carefully weigh the environmental and community impacts of truck transport versus rail transport. Truck transport entails environmental risks and costs such as spills, fuel emissions, increased neighborhood traffic, and noise. An on-site transfer facility followed by rail transport may be the best option. When EPA has more details about the various options, we look forward to participating in the discussion to determine the best approach.

**EPA Response**

The 2016 feasibility study report (USEPA 2016) looks at modes of transport and associated transload of wastes from a macro perspective, but the primary assumption in the feasibility study was to use barges for the purposes of implementability and cost evaluation. The feasibility study also indicated that multiple modes of transport could be used and could be evaluated during remedial design phase of the project. As has been demonstrated on the Gasco and Terminal 4 early actions, transload facilities can be efficiently built and optimized to suit the needs of the Portland Harbor cleanup in a vicinity to landfills that often reduces greenhouse gas emissions by extending barge or rail haul mileage, and minimizes truck haul mileage. See also Section 2.22 of this responsiveness summary.

**3.1.77 Select a Time Period Greater than 100 Years for Evaluation****Comment**

EPA's evaluation of the ability of PTW to be reliably contained assumes a 100-year time period (EPA 2016b, p. D-20). The Five Tribes emphasize the importance of a remedy that is protective in perpetuity, not merely for 100 years. Would the results of the evaluation differ if EPA had used a longer time period? If so, we urge EPA to select a longer time period for the evaluation.

**EPA Response**

Representative Site conditions and capping options were modeled using this approach to determine the maximum concentrations of PTW material that would not result in exceedances of AWQC in the sediment cap pore water after a period of 100 years to be consistent with the long-term costing

conducted in Appendix G of the 2016 feasibility study report (USEPA 2016b). EPA does not believe that the results of the evaluation would have differed significantly if a longer time period had been used. EPA will extend this modeling time frame if future monitoring shows that the remedy may lose its protectiveness.

### 3.1.78 Ensure EPA’s Definition of Shallow Water Matches that Used by NMFS

#### Comment

The feasibility study report explains that “The determination of 4 feet NAVD88 as the boundary for [the shallow] region was based on an assumed cap thickness of 3 feet (if capping were to be applied) and a mean low water level elevation of 7 feet NAVD88” (EPA 2016b, p. 3-11). We do not know how this definition of shallow water relates to the NMFS definition of shallow water of 20 feet below mean low water level. We support the authority of the NMFS for determining habitats that are of importance to fish. It is our understanding that EPA gives separate consideration to shallow water areas due to the important habitat value that these areas provide to aquatic life. We ask that EPA ensure that their definition of shallow water is consistent with the NMFS definition.

#### EPA Response

NMFS defines shallow water as above -15 feet CRD and EPA is coordinating with NMFS to ensure consistency. EPA will continue to coordinate with NMFS during remedial design to ensure sufficient consideration of Endangered Species Act and other non-ESA aquatic species. Habitat features will also be considered in other regions, as needed, for ESA and other non-ESA aquatic species. Also see Section 5 of this responsiveness summary.

### 3.1.79 Conduct a Flood Rise Evaluation Using a DMM Scenario

#### Comment

The Five Tribes do not agree with EPA’s reasoning for not including Disposed Material Management (DMM) Scenario 1 in the Flood Rise Evaluation presented in Appendix P of the feasibility study report (EPA 2016b, p. P-3). Some uncertainties may exist regarding the siting and construction of the CDF. However, sufficient certainty exists (e.g., the existence of a 60 percent design and the assumption of the Terminal 4 location) to justify conducting a “ cursory evaluation ” of the sort presented in Appendix P. The CDF will undoubtedly convert a portion of the Willamette River into upland, which will affect flood rise. We request that EPA conduct such an analysis in order to allow for a more complete understanding of the effects of a potential CDF.

#### EPA Response

See Section 2.14.1.

### 3.1.80 Determine Dredging Practices that Are the Most Protective

#### Comment

The Five Tribes are very much in favor of the implementation of any measures that would prevent incidental and accidental discharges of contaminated materials into the water column. EPA identifies several BMPs and “precautions and controls” (EPA 2016b, p. 4-37). Unfortunately, factual support for the effectiveness of these methods is scant in the remediation literature. Implementation of these methods may not increase protectiveness and could decrease overall performance (for instance, in terms of construction duration and cost). The effectiveness of these methods should be examined. For instance, what are the impacts of installing and removing sheet piles? Do sheet piles disturb and redistribute contaminated sediment? How much of a carbon footprint is created by having to

manufacture, transport, install, remove, and recycle the sheet pile? What other wastes are produced in the process? BMPs such as sheet piles are often heavily marketed by vendors, but there is little sound science on their effectiveness. We ask that EPA review the relevant literature and consult with experts in remedial dredging to determine the measures with the greatest likelihood of reducing discharges and increasing environmental protectiveness.

#### **EPA Response**

See LSS Dispute Issue 16 (Appendix A of this document) and Sections 2.21 and 2.22 of this responsiveness summary.

### **3.1.81 Clarify Referencing of Figures 4.2-9 through 4.2-17**

#### **Comment**

Figures 4.2-9 through 4.2-17 of the feasibility study appear to depict predicted ecological risk post-construction for each alternative. (We assume that, despite the figure captions, these figures are not intended to show residual risk as defined in the feasibility study; that is, risk once PRGs are achieved.) These figures are helpful in comparing alternatives. However, it is not clear how the depicted COCs were selected: some are focused COCs and some are not. These figures do not appear to be referenced in the text. We recommend that EPA include an in-text explanation of the figures.

#### **EPA Response**

Figures are referenced in the text under “Overall Protection of Human Health and the Environment” and “Long-Term Effectiveness and Permanence” for each alternative.

### **3.1.82 Use Enforcement Measures to Obtain PRP Compliance**

#### **Comment**

We support a timely implementation of the remedy. Ideally, responsible parties will fully cooperate with EPA to construct the remedy as quickly as possible. However, if needed, we support EPA’s use of enforcement actions to compel responsible parties to cooperate.

#### **EPA Response**

Comment noted.

### **3.1.83 Describe Decision-Making for Adaptive Management and Future Monitoring**

#### **Comment**

The proposed plan and feasibility study provide insufficient detail on monitoring activities. The success of the remedy is dependent on diligent monitoring activities to identify and correct any potential technology failures before they cause widespread recontamination. Monitoring is also essential for determining whether the Site achieves protective levels within a pre-determined period of time; if it does not, a ROD amendment may be needed to require additional remediation. The importance of this monitoring cannot be overstated. As such, we strongly encourage EPA to provide additional information regarding their anticipated monitoring activities and reporting of monitoring data. In the ROD, we expect to see details regarding how often monitoring will be conducted, who will conduct it, who will oversee it, and what reporting will be required. We request that the ROD describe in detail the decision-making process regarding monitoring and adaptive management; specifically, how monitoring data will be used to inform construction activities and future monitoring.

**EPA Response**

See Sections 2.17 and 2.28.1 of this responsiveness summary.

**3.1.84 Identify Time-Dependent Decision Points****Comment**

The ROD should identify time-dependent decision points for the purpose of determining progress toward achieving remediation goals as well as the actions that would be taken should sufficient progress not be made. Specific standards or interim goals should be stated for each five-year review that would trigger the need for additional active remediation. For example, will EPA evaluate whether the cleanup actually achieves the interim targets post-construction? If interim targets are not met, what actions will EPA take? Because EPA assumes that interim targets will be met immediately post-construction, if these targets are not met by the five-year review, additional remediation may be warranted. The Site should be evaluated on a site-wide, SDU, and river mile basis. All relevant media (sediment, fish tissue, river bank soil, beach soil/sediment, surface water, pore water) should be considered.

**EPA Response**

Interim targets identified in the 2016 feasibility study report (USEPA 2016b) will be used as one of many lines of evidence that will be evaluated against empirical data collected under a robust monitoring plan for the Site to make sure the remedy is on track to achieve clean up levels.

**3.1.85 Clarify the Schedule for Five-Year Reviews****Comment**

EPA notes that “Upland source control measures will... need to be evaluated for necessary repairs and maintenance performed under five-year reviews of the CERCLA action” (EPA 2016b, p. 4-12). While we understand that a comprehensive review of upland source control measures will occur during the five-year reviews, it is our expectation that the success of individual upland source control measures, particularly more significant ones, will be evaluated more frequently than once every five years, either by DEQ or EPA. The frequency of monitoring should depend on the characteristics of the particular measure.

**EPA Response**

See Section 2.27 of this responsiveness summary.

**3.1.86 Engage the Tribes throughout the Remediation Process****Comment**

Of great importance to the Five Tribes is that we remain engaged throughout remedial design and be given opportunities to provide feedback, including instances where EPA is considering granting the responsible parties the opportunity to deviate from the ROD. We expect that our involvement during remedial design will include, but not be limited to, providing meaningful input on the development and review of work plans, sampling and analysis plans, data reports, monitoring, design plans, and granting any deviations from the preferred alternative due to unforeseen design or field challenges. In particular, we expect to be given the opportunity for input on the consideration of any additional remediation (through a ROD amendment) or a technical impracticability or other ARAR waiver.

**EPA Response**

Throughout the process, EPA has fostered meaningful engagement with the MOU partner tribes and has encouraged and facilitated tribal involvement. In accordance with EPA's Policy on Consultation and Coordination with Indian Tribes, EPA also held consultation meetings at tribal council locations from January 12 through February 4, 2016 and from July 19 through July 26, 2016, during the public comment period on the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c). In addition, representatives for the Confederated Tribes and Bands of the Yakama Nation met with Administrator McCarthy on July 26, 2016 in Washington, D.C. A summary of the consultation meetings, along with any written materials provided, are in the Administrative Record.

The consultation process also included discussions on treaty rights, in accordance with the Treaty Rights Guidance. The Treaty Rights Guidance was issued to provide assistance on consultation regarding EPA actions occurring in a specific geographic area where tribal treaty rights may exist in, or treaty-protected resources may rely on, that area. Government-to-government consultations occurred in January and February of 2016 in anticipation of the proposed plan.<sup>2</sup> EPA will continue this working relationship for tribal input under the MOU and EPA's Policy on Consultation and Coordination with Indian Tribes, to ensure that tribal concerns and interests are considered whenever EPA actions may affect tribal communities – both related to treaty rights and other impacts. The ROD includes language regarding tribal coordination and consultation and community involvement in all activities post ROD.

The Portland Harbor Site is complex and the remedy preferred by EPA to perform an effective cleanup under these complexities will require an ongoing partnership and collective input from both the state and the tribes in communication with EPA, for critical decisions made throughout the implementation of the in-river cleanup.

**3.1.87 Collect Additional Data Regarding Erosion and Deposition During Remediation****Comment**

During remedial design, it is imperative to collect additional data regarding erosion and deposition trends in the Site. This will help in identifying areas that may be inappropriate for certain technology assignments (e.g., MNR in erosive areas). We suggest conducting field and laboratory studies to measure sediment stability (or erodibility) using tools such as Sedflume, Gust Microcosm, and consolidation tests.

**EPA Response**

The feasibility study states in several places that additional data will be collected during remedial design to assist in refining the remedy beyond the feasibility study-level of analysis and the ROD

---

<sup>2</sup> EPA Policy on Consultation and Coordination with Indian Tribes, May 4, 2011. Incorporates the Executive Order 13175 "Consultation and Coordination with Indian Tribal Governments," November 2000 and Presidential Memorandum, November 5, 2009. See also EPA Policy on Consultation and Coordination with Indian Tribes: Guidance for Discussing Tribal Treaty Rights, February 22, 2016.

reflects this as well. EPA intends to collect and evaluate additional data during remedial design to refine the following: delineation of contamination, selection and design of remedial technologies and construction methods, projections of natural recovery, treatment and disposal requirements, measures for aquatic and listed species protection, and compensatory mitigation requirements, to name a few.

Specific tools required or used for pre-design investigation will be determined during remedial design phase and will be based on scope, objective and usability of the data.

### 3.1.88 Incorporate Effective BMPs in Remedial Design to Reduce Fish Mortality

#### Comment

In accordance with methods outlined in the working draft Programmatic Biological Assessment (FWS and NMFS 2016), we request that EPA incorporate effective BMPs during remedial design for reducing the mortality of fish, including lamprey, during construction (FWS 2010).

#### EPA Response

Comment noted.

## 3.2 Confederated Tribes and Bands of the Yakama Nation

### 3.2.1 Eliminate Health Advisories as a Result of Toxic Releases

#### Comment

Provide a cleanup that results in fish that are clean, healthy and safe to eat. The cleanup should be aggressive enough to eliminate health advisories as a result of toxic releases from Portland Harbor. The proposed plan uses fish consumption advisories, instead of adequate cleanup, to protect human health. The restoration timeframe of 30 years is unsupported and it is unknown if these ICs can ever be lifted.

#### EPA Response

EPA's strategy is to utilize a mix of technologies (including dredging, capping, ENR, and MNR) to address contamination in the waterway to the maximum extent practicable using engineering controls, and minimizing the use of ICs to further reduce risks. Together, these will protect human health and assure overall protectiveness of the remedy.

EPA recognizes that the remedy likely will not reduce the concentrations of PCBs and other contaminants to levels low enough to allow for consumption at the higher consumption rates associated with subsistence fishing. The scope of the CERCLA action is restricted to approximately 10 miles of the Willamette River, but upstream of the Site, background levels of PCBs from "clean" areas exceed the acceptable range based on conservative risk estimates, meaning that even with a more stringent remedy in place proposed fish advisories would likely remain in effect following the cleanup. Therefore, fish advisories would remain in effect following the cleanup but would be less restrictive because the highest concentrations of bioaccumulative contaminants in sediment would be removed or capped such that they no longer enter the food chain within the Site. Watershed-wide implementation of source reductions through water quality programs by the Oregon Department of Environmental Quality in conjunction with source control activities at the Site are expected to contribute to the elimination of fish consumption advisories under EPA's ROD. Although CERCLA-related fish advisories would remain in place until cleanup levels are achieved, Oregon Health Authority may still impose an advisory based on broader watershed risks.

ICs will be used to prevent or limit exposure to contaminants on both a short- and long-term basis. Fish consumption advisories would be required until such time as RAO 2 is achieved as demonstrated through fish tissue monitoring. EPA expects to work with the Oregon Health Authority to revise the advisories to be consistent with the ROD. Outreach would be conducted to educate the public about the fish consumption advisories. Informational materials will be evaluated to determine advisory effectiveness. Thus, the feasibility study acknowledges that fish consumption advisories will be implemented after construction until PRGs are met and that the use of fish consumption advisories and education and outreach programs will provide additional risk reduction. Also see Sections 2.28 and 3.1.43 of this responsiveness summary.

### 3.2.2 Provide More Aggressive Cleanup in Erosional Areas

#### Comment

EPA used SEDCAM modeling along with several other lines of evidence (bathymetry, percent fines, propeller wash areas, wind/wake conditions, and subsurface to surface sediment concentration ratios) to forecast the success of MNR in reaching cleanup goals following active remediation. Given the great deal of uncertainty associated with modeling, EPA will focus greatly on the development of a robust monitoring plan following the ROD to evaluate achievement of cleanup goals with empirical data. The SEDCAM modeling results show that the selected remedy, Alternative F Modified, is protective within a reasonable timeframe given the uncertainty in the model. Prevent the release of contaminated sediments into the Columbia River. EPA's overreliance on natural recovery will allow for the continued release of persistent and bioaccumulative contaminants to the Columbia River, putting our fish and people at risk. In addition to using lower Alternative G dredge decision criteria, the ROD should provide more aggressive cleanup measures in erosional areas.

#### EPA Response

The selected remedy, Alternative F Modified further reduces reliance on MNR over the proposed plan's Alternative I (USEPA 2016c). The selected remedy does not overly rely on MNR. Although the selected remedy calls for 1,774 acres to be addressed by MNR, MNR is only designated to be applied to areas of low level contamination, where active remediation's impact to the ecosystem is considerably larger (on the order of decades of additional construction time) for the gains achieved. Based on the conceptual site model, areas with levels of contamination greater than the RALs where MNR would not be effective in reducing contaminant levels and ultimately risks, were assigned dredging or capping. A detailed baseline sampling program will be conducted in the remedial design phase to redefine areas suitable for active cleanup and for MNR. Specific monitoring goals to measure MNR progress will be developed in remedial design. Should MNR not achieve cleanup levels or progress sufficiently toward achieving them, additional actions (dredging, capping, or ENR) will be analyzed and may be implemented.

### 3.2.3 Clarify the Role of the Confederated Tribes and Bands of the Yakama Nation in Overseeing Cleanup

#### Comment

Include language regarding Yakama's Nation's role in overseeing the cleanup. The Yakama Nation expects to be fully engaged and an active participant in oversight throughout the cleanup process.

#### EPA Response

Throughout the remedial investigation/feasibility study process, EPA has fostered meaningful engagement with the MOU partner tribes and has encouraged and facilitated Tribal involvement. In

accordance with EPA’s Policy on Consultation and Coordination with Indian Tribes, EPA also held consultation meetings at tribal council locations from January 12 through February 4, 2016 and from July 19 through July 26, 2016, during the public comment period on the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c). In addition, representatives for the Confederated Tribes and Bands of the Yakama Nation met with Administrator McCarthy on July 26, 2016 in Washington, D.C. A summary of the consultation meetings, along with any written materials provided, are in the Administrative Record.

The consultation process also included discussions on treaty rights, in accordance with the Treaty Rights Guidance. The Treaty Rights Guidance was issued to provide assistance on consultation regarding EPA actions occurring in a specific geographic area where tribal treaty rights may exist in, or treaty-protected resources may rely on, that area. Government-to-government consultations occurred in January and February of 2016 in anticipation of the proposed plan.<sup>3</sup> EPA will continue this working relationship with the Yakama Nation under the MOU and EPA’s Policy on Consultation and Coordination with Indian Tribes, to ensure that the tribal government’s concerns and interests are identified and considered whenever EPA actions may affect tribal interests, including those related to treaty rights. The ROD includes language regarding tribal government consultation and coordination and community involvement in all activities post ROD.

The Portland Harbor Site is complex and the remedy preferred by EPA to perform an effective cleanup under these complexities will require an ongoing partnership and collective input from the Yakama Nation and the state in communication with EPA, for critical decisions made throughout the implementation of the in-river cleanup, including during five-year review evaluations of cleanup progress.

### 3.2.4 Uphold the Federal Trust Responsibility

#### Comment

EPA must uphold its federal trust responsibility by clarifying roles. EPA cannot delegate its federal trust responsibility to the State of Oregon. We are opposed to a state-led implementation of the in-river cleanup at the Site.

#### EPA Response

EPA is committed to maintaining its long-standing work with federally recognized Indian tribes on a government-to-government basis. Indeed, one of the key principles of the EPA Policy for the Administration of Environmental Programs on Indian Reservations (1984) is that “The Agency, in Keeping with the federal trust responsibility, [EPA] will assure that Tribal Concerns and Interests Are Considered Whenever Its Actions And/Or Decisions May Affect May Affect Reservations Environments.” In the case of the Portland Harbor Site, EPA engaged in significant consultation and coordination with tribes, including holding face-to-face meetings at tribal council locations from January 12 through February 4, 2016 and from July 19 through July 26, 2016, during the public

---

<sup>4</sup> EPA Policy on Consultation and Coordination with Indian Tribes, May 4, 2011. Incorporates the Executive Order 13175 “Consultation and Coordination with Indian Tribal Governments,” November 2000 and Presidential Memorandum, November 5, 2009. See also EPA Policy on Consultation and Coordination with Indian Tribes: Guidance for Discussing Tribal Treaty Rights, February 22, 2016.

comment period on the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c). In addition, representatives for the Confederated Tribes and Bands of the Yakama Nation met with Administrator McCarthy on July 26, 2016 in Washington, D.C. The consultation process also included discussions on treaty rights. The Administrative Record contains a summary of the consultation meetings, along with any written materials provided. These consultation and coordination efforts took consistent with the EPA Policy on Consultation and Coordination with Indian Tribes and EPA Guidance for Discussing Tribal Treaty Rights. The Treaty Rights Guidance is designed to provide assistance on consultation regarding EPA actions occurring in a specific geographic area where tribal treaty rights may exist in, or treaty-protected resources may rely on, that area.

The ROD includes language regarding tribal coordination and consultation and community involvement in all activities post ROD. The Site is complex and the remedy preferred by EPA to perform an effective cleanup under these complexities will require an ongoing partnership and collective input from both the tribes and Oregon in communication with EPA, for critical decisions made throughout the implementation of the in-river cleanup.

EPA will continue this working relationship for tribal government input under the MOU, EPA's Policy on Consultation and Coordination with Indian Tribes and the Tribal Treaty Rights Guidance, to ensure that tribal concerns and interests are considered whenever EPA actions may affect tribal interests.

### 3.2.5 Meet Threshold Requirements for Protectiveness

#### **Comment**

Meet threshold requirements for protectiveness. The proposed plan does not meet or is uncertain to meet multiple interim risk targets.

#### **EPA Response**

As a long-term model is not available to predict the time to meet the PRGs, interim targets for risks and HIs were developed for feasibility study purposes. These targets will be used to evaluate each alternative's effectiveness in achieving cleanup goals both immediately after construction and long term.

Based on recommendations from the NRRB/CSTAG (see NRRB/CSTAG comment on Remedy Performance, p. 5), EPA performed an uncertainty analysis of each alternative to determine the likelihood that the Alternative would be significantly different from the No Action alternative. This analysis was presented in Appendix I of the 2016 FS, and the conclusion was that Alternative B post-construction SWACs were statistically indistinguishable from the No Action alternative and that the post-construction SWACs for Alternative D were still within the margin of error relative to no action. Although Alternatives B and D are expected to be protective of human health through ICs and MNR, the uncertainty of the post-construction SWACs indicates that Alternatives B and D may not be protective of the environment because of the time frame needed to achieve PRGs through MNR and ICs would not provide protection of ecological receptors during this time period. Alternative G is the only alternative to meet all interim targets; however, Alternative G involves a significantly greater amount of construction area and time (19 years), and thus, would have the highest cost, most impact to the community and Lower Willamette River ecosystem, workers and the environment during construction. Alternative G was not selected as the preferred alternative because of the difficulty associated with managing short-term impacts, the high cost and increased difficulty of implementation.

Five-year reviews will be conducted the purpose of which is to determine whether the remedy is, or upon completion will be, protective of human health and the environment. Should the remedial action or MNR not achieve cleanup levels or progress sufficiently toward achieving them and the corresponding ARARs, additional actions (dredging, capping, or ENR) may be required to meet the remedial cleanup goals (see Section 2.16.1 of this responsiveness summary).

### 3.2.6 Comply with ARARs

#### Comment

Comply with ARARs. The cleanup must comply with state water quality and hazardous substance remedial action rules for risk.

#### EPA Response

As discussed in Section 3.2.5, five-year reviews will be conducted the purpose of which is to determine whether the remedy is, or upon completion will be, protective of human health and the environment. Should the remedial action or MNR not achieve cleanup levels or progress sufficiently toward achieving them and the corresponding ARARs, additional actions (dredging, capping, or ENR) may be required to meet the remedial cleanup goals (see Sections 2.3.1 and 2.16.1 of this responsiveness summary).

### 3.2.7 Remove all PTW

#### Comment

Remove all PTW to assure maximum reduction of risk for the life of the remedy. It will take 100s to 1,000s of years for contaminants to degrade. Capping PTW in place provides little to no assurance that future releases will not occur on this time scale, and in a river environment that is set in a tectonically active region as well as subject to climate change.

#### EPA Response

Refer LSS Dispute Issue 17 (Appendix A of this document) and Section 2.5 of this responsiveness summary.

### 3.2.8 Protect Shorelines and Nearshore Habitat

#### Comment

Protect shorelines and nearshore habitat. A significant portion of the affected benthic receptors, as well as river bank and groundwater source areas are unaddressed in the proposed plan and need clarification in the ROD.

1. The river bank and groundwater cleanups should not be dealt with separately by the state, and should be addressed more specifically in the ROD.
2. A greater portion of the area exceeding benthic criteria should be cleaned up.
3. Higher value habitat areas should be given additional consideration for a more protective cleanup.

#### EPA Response

The selected remedy addresses not only the sediment, pore water and surface water of the lower Willamette River from approximately RM 1.9 (at the upriver end of the Port of Portland's Terminal 5) to RM 11.8 (near the Broadway Bridge), but also addresses portions of the river banks adjacent to

SMAs which were identified by DEQ during feasibility study development. River bank remediation has already occurred at some locations in the Site.

Refer LWG Dispute Issue 1b (Appendix A of this document) for a discussion on benthic criteria.

The determination of higher value habitat areas can be further evaluated in the remedial design phase. See also Section 2.8.1 of this responsiveness summary.

### 3.2.9 Evaluate Upland Source Control and Provide Assurances

#### Comment

Include an evaluation of upland source control and provide assurances that upland sources will not affect the in-river cleanup efforts. Adequate upland source control measures must be in place prior to the cleanup to protect the river from recontamination. EPA needs to take a more active role in ensuring these source controls move forward and are adequate.

#### EPA Response

See Sections 2.26 and 2.27.

### 3.2.10 Include a Contingency Plan

#### Comment

Include a contingency plan. proposed plan projections for natural recovery of multiple contaminated media are unsupported and highly uncertain. A contingency plan with a clear decision criterion is necessary to correct the recovery trajectories if the Site is not adequately trending towards the cleanup goals.

#### EPA Response

See Sections 2.16.1 and 2.17.3 of this responsiveness summary.

### 3.2.11 Honor Confederated Tribes and Bands of the Yakama Nation Treaty Rights

#### Comment

The Yakama Nation is the legal successor in interest to the Indian signatories to the Treaty with the Yakamas of June 9, 1855 (12 Stat. 951). Under Article III of the Treaty, the Yakama Nation has reserved for itself and its members the right to take fish at all “usual and accustomed places.” The term “usual and accustomed places”, with respect to fishing, is defined as “every fishing location where members of a tribe customarily fished from time to time at and before treaty times, however distant from the then usual habitat of the tribe, and whether or not other tribes then also fished in the same waters.” U.S. v. Washington, 384 F.Supp. 312 (W.D.Wash. 1974). Since time immemorial, Yakama people have migrated, lived, and fished in the Lower Columbia River tributaries. The Willamette River is recognized by the Yakama Nation as a usual and accustomed fishing place, and has always been an important food gathering area. Every June and July enrolled Yakama members travel to Willamette Falls to collect the culturally important Asúm eel, also known as the Pacific Lamprey, for traditional ceremonies and subsistence.

The nature and scope of the Yakama Nation’s off-reservation treaty reserved fishing rights on the Columbia River and its tributaries has been extensively litigated through participation as an original plaintiff-intervener in the continuing jurisdiction case of United States v. Oregon (Civil No. 68-513-KI, D. Or.). See *Sohappy v. Smith*, 302 F. Supp. 899 (D.Or. 1969); *United States v. Oregon*, 913 F.2d 576

(9th Cir. 1990). In 1977, the Yakama Nation participated in the creation of the Columbia River Inter-Tribal Fish Commission, which provides technical and policy assistance to four treaty tribes in their management of Columbia River fisheries. In 2008 the parties to *U.S. v. Oregon* signed a ten-year Management Agreement for tribal and state co-management of Columbia River anadromous fish species, entered as an enforceable order of the U.S. District Court. The Yakama Nation is recognized as a trustee under CERCLA for any natural resources “belonging to, managed by, controlled by, or appertaining to” the tribe within the Columbia Basin, including in the Willamette River. 42 U.S.C. § 9607(f)(1).

In recent years, the Yakama Nation has participated as *amicus curiae* in numerous legal actions involving the National Marine Fisheries Service’s administration of the Endangered Species Act with respect to listed salmon and steelhead stocks, to which the tribe holds treaty-reserved fishing rights. See, e.g., *National Wildlife Federation, et. al., v. NMFS, et. al.* (Civil No. 01-640-SI, D. Or); *American Rivers, et. al. v. NMFS, et. al.* (Civil No. 96-384-MA, D. Or). The Yakama Nation also protect its interests and legal rights via the following representative sample of activities: fish habitat restoration efforts, many of which are detailed in the Columbia Basin Fish Accords; participation in the ongoing processes for the development of Endangered Species Act Recovery Plans for listed salmon and steelhead; development and implementation of fishing management plans as a party to *U.S. v. Oregon*; implementation of the Pacific Salmon Treaty through participation in the Pacific Salmon Commission processes (see 16 U.S.C. 3631, et. seq.); and participation in a variety of other policy and technical committees and organizations dealing with issues related to the protection and rebuilding of salmon, steelhead, lamprey, and other species throughout the Columbia River basin.

Significantly, the Yakama Nation continues to participate in numerous environmental response actions throughout the Columbia Basin being conducted under both CERCLA and state cleanup laws. If the Yakama Nation conducts or participates in a response action it is entitled to recover all costs of removal or remedial action incurred by the tribe [that are] not inconsistent with the NCP. 42 U.S.C. § 9607(a)(4)(A); see also *Confederated Tribes and Bands of the Yakama Nation v. U.S. Dept. of the Army, et. al.* (Civil No. 14-1963-PK, D. Or), Findings and Recommendation (ECF No. 33, Dec. 18, 2015).

Based on these legal authorities, EPA in its Record of Decision must specifically acknowledge the role that the Yakama Nation will have in the design and implementation of the remedial action for Portland Harbor. The tribe’s participation in the Remedial Design/Remedial Action (RD/RA) phase of the CERCLA cleanup is critical to the upholding of treaty reserved rights in the Lower Columbia Basin, and will also greatly assist in EPA’s statutory mandate for protection of human health and the environment. EPA must ensure that the Yakama Nation has the means to fully engage with agencies and actively participate in oversight throughout the RD/RA process.

### **EPA Response**

Throughout the process, EPA has fostered meaningful engagement with the MOU partner tribes and has encouraged and facilitated Tribal involvement, consistent with EPA’s Policy on Consultation and Coordination with Indian Tribes, EPA also held consultation meetings at tribal council locations from January 12 through February 4, 2016 and from July 19 through July 26, 2016, during the public comment period on the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c). In addition, representatives for the Confederated Tribes and Bands of the Yakama Nation met with Administrator McCarthy on July 26, 2016 in Washington, D.C. A summary of the consultation meetings, along with any written materials provided, are in the Administrative Record.

The consultation process included discussions on treaty rights, in accordance with the February 2016 Guidance for Discussing Tribal Treaty Rights (Treaty Right Guidance). The Treaty Rights Guidance was issued to provide assistance on consultation regarding EPA actions occurring in a specific geographic area where tribal treaty rights may exist in, or treaty-protected resources may rely on, that area. Government-to-government consultations occurred in January and February of 2016 in anticipation of the proposed plan.<sup>4</sup> EPA will continue this working relationship for tribal input under the MOU and EPA's Policy on Consultation and Coordination with Indian Tribes, to ensure that tribal concerns and interests are considered whenever EPA actions may affect tribes— both related to treaty rights and other impacts. The ROD includes language regarding consultation and coordination with tribal governments and community involvement in all activities post ROD. Further, once implemented, the cleanup will improve fish habitat and help further the tribes' rights to fish.

The Site is complex and the remedy preferred by EPA to perform an effective cleanup under these complexities will require an ongoing partnership and collective input from both the tribes and Oregon in communication with EPA, for critical decisions made throughout the implementation of the in-river cleanup.

### 3.2.12 Recognize Trust Responsibility

#### Comment

EPA has for many years expressly recognized its fiduciary duty toward Indian tribes. See, e.g., EPA Policy for the Administration of Environmental Programs on Indian Reservations (November 8, 1984) at 3. Federal courts have recognized the trust responsibility toward tribes in EPA's actions conducted under federal environmental statutes, including those affecting tribal resources outside Indian reservations. *Nance v. Environmental Protection Agency*, 645 F.2d 701 (9th Cir. 1981). EPA's most recent tribal consultation policy also reaffirms this principle as a foundation of its relationship with Indian governments. EPA Policy on Consultation and Coordination with Indian Tribes (May 4, 2011) at 3.

Courts generally hold that the nature of the trust responsibility and its specifics are defined by Congress. *United States v. Mitchell*, 445 U.S. 535 (1980). This includes a duty to protect the exercise of fishing rights reserved by a treaty with the United States. *Parravano v. Babbitt*, 70 F.3d 539, 546 (9th Cir. 1995). The duty is also enforceable in CERCLA through certain statutory provisions applying to treatment of Indian tribes enacted by Congress in 1986 through the Superfund Amendments and Authorization Act (SARA). 42 U.S.C. § 9626(a). These include the requirement that EPA consult with affected tribes "before determining any appropriate remedial action to be taken." 42 U.S.C. § 9604(c)(2). CERCLA also requires lead agencies to coordinate with tribes as trustees in "assessments, investigations, and planning" of all response actions. 42 U.S.C. § 9604(b)(2); see also 40 CFR § 300.615(c)(1)(ii). CERCLA and the NCP should be construed broadly to include the remedial

---

<sup>4</sup> EPA Policy on Consultation and Coordination with Indian Tribes, May 4, 2011. Incorporates the Executive Order 13175 "Consultation and Coordination with Indian Tribal Governments," November 2000 and Presidential Memorandum, November 5, 2009. See also EPA Policy on Consultation and Coordination with Indian Tribes: Guidance for Discussing Tribal Treaty Rights, February 22, 2016.

design/remedial action (RD/RA) phase of response actions in these fiduciary duties. See, e.g., *Carson Harbor Village v. Unocal Corp.*, 270 F.3d 863 (9th Cir. 2001).

However, the federal government may not delegate its trust responsibilities to state agencies. See *Assiniboine and Sioux Tribes v. Board of Oil and Gas*, 792 F.2d 782 (9th Cir. 1986). This is a critical issue for the Portland Harbor cleanup because Oregon Department of DEQ has expressed an interest in implementing either part or all of the RD/RA phase of the in-river cleanup. Whether this is done directly through CERCLA or under the Oregon Environmental Cleanup Law, ORS 465.200 et. seq., EPA will still retain a fiduciary duty to the tribe to protect its legal interests under the Treaty of 1855. For this reason, the Yakama Nation objects to any transfer of oversight to DEQ. Our concerns are especially relevant to ensuring that the remedial action meets appropriate cleanup standards for treaty protected fisheries, as well as the expected negotiation of funding and participation agreements with PRPs for the RD/RA phase.

As you know, our experience with Yakama's participation in the Astoria Marine Construction Co. (AMCCO) site in Clatsop County has been a glaring illustration of what can go horribly wrong when EPA transfers or delegates its authority to the State of Oregon. In 2012, Region 10 deferred its proposed placement of the site on the NPL by placing oversight in the hands of DEQ. One of the conditions that EPA had put on the deferral was assurance of support for tribal involvement, and both DEQ and AMCCO were clearly notified that this would involve funding of tribal participation as well. However, in the past four years AMCCO has engaged in numerous disputes with the Yakama Nation regarding a number of funding issues, including annual budgets, indirect costs, and attorney fees. These disagreements jeopardized the tribe's full participation, and created unprecedented cost overruns and administrative headaches. DEQ meanwhile took a "hands off" approach to these problems, arguing that it has no authority to enforce or otherwise get involved with the company's funding of Yakama's participation in the cleanup. This approach has also been exemplified by the lack of coordination by DEQ project managers at other sites including Bradford Island and Mosier.

Unless EPA ensures that the tribe will have an enforceable mechanism for ensuring that EPA upholds its trustee role in the context of state remedial actions, the Yakama Nation must oppose any plan to delegate in-river cleanup responsibilities to DEQ. Any transfer of oversight to the State of Oregon without any written guarantee that the Yakama Nation's cleanup role will be adequately recognized and funded, or the tribe's treaty resource interests strictly protected, will be considered a serious violation of EPA tribal consultation policies and fiduciary duties.

### **EPA Response**

In a February 2001 Memorandum of Understanding (USEPA 2001), it was agreed that EPA would take the Lead Agency role and DEQ would take the Support Agency role for the in-river cleanup while DEQ would take the Lead Agency role and EPA would take the Support Agency role for addressing upland and upriver contamination that may impact the Willamette River. EPA expects that cleanup work conducted as part of this ROD will be performed by the PRPs under CERCLA authorities and EPA oversight. In order to maximize resources and achieve cleanup as soon as possible, there may be an opportunity for DEQ to perform certain technical oversight functions, in coordination with EPA, at specified areas of the in-river portion of the Site. Any oversight functions performed, whether performed by EPA or DEQ, will comply with CERCLA, the NCP, the ROD, any CERCLA agreements reached between the agencies and work parties, and EPA policy and guidance regarding CERCLA cleanup actions. Throughout the cleanup process, EPA will maintain its commitment to consultation and coordination with tribes and act in accordance with its tribal trust responsibility.

ICs with respect to the governmental entity that will provide enforcement authority will be determined during the development of remedial design and identification of responsibility in an ICs implementation and assurance plan and an operation and maintenance plan. These plans will be developed jointly by a team made up of representatives from EPA, DEQ, tribes, Oregon Department of State Lands, Coast Guard, Oregon Marine Board, Oregon Department of Transportation, USACE, City of Portland, Port of Portland, and others.

### 3.2.13 Revisit Site Boundaries versus Study Area

#### Comment

To date, EPA has failed to take into consideration the releases from the Site to the lower Columbia River. The proposed plan does not adequately describe the loading and potential impacts to resources beyond the Site boundaries. We argue that the Site boundaries are really a “study area”, which is the terminology used in the original Remedial Investigations. By CERCLA definition, a site includes anywhere a hazardous substance has come to be located. Contamination from the Site does not stop at the downstream Site boundary. However, for the sake of expediency, EPA and the PRPs artificially and arbitrarily truncated the downstream Site boundary, leaving downstream Site contamination unaddressed. Data conclusively show that Site contamination exceeds toxicity criteria at and beyond the downstream boundary and that Site contaminant loads are transported further downstream and into the Columbia River.

#### EPA Response

See Section 2.2.10 of this responsiveness summary.

### 3.2.14 Monitor for Impacts to Species

#### Comment

Harmful and toxic pollutants from the Willamette River are carried into the Columbia River and have been found in salmon below the confluence of these two rivers. Portland Harbor is contributing highly toxic PCBs, DDT, polycyclic aromatic hydrocarbons (PAHs), dioxins/furans, and other persistent and bioaccumulative pollutants to the Columbia River. As a result, the health of juvenile salmon in the Columbia River is impaired by exposure to these contaminants. Juvenile salmon slow down and spend extra time in the Columbia River estuary to acclimate, feed and grow before heading out to sea. Pacific lamprey and sturgeon are also at risk from these toxic substances. Lamprey ammocoetes live and feed in the Site sediments for up to 7 years before migrating; however, Site monitoring to date on lampreys has been inadequate. Resident fish downgradient of the arbitrary Site boundary have not been adequately monitored for contaminants, despite the known sediment loading to the Columbia River.

#### EPA Response

See Sections 2.2.10, 2.16, 2.17, 2.23, and 2.33.2 of this responsiveness summary.

### 3.2.15 Recognize Impacts on Endangered Species Recovery Efforts

#### Comment

Federal, state, tribal, and many local partners are working to support the recovery of salmon, steelhead, and other Endangered Species Act listed fish species in the lower Columbia River and its tributaries. Since 1978, Bonneville Power Administration has invested \$2.68 billion in fish recovery in the Columbia River watershed. Considerable resources (on the order of \$200 million annually) are directed towards these efforts in order to abate the decline of these species and move toward their

recovery. The inadequacies of the proposed plan are contradictory to these investments of public dollars in fisheries recovery.

**EPA Response**

See Subsection 2.19 of this responsiveness summary.

**3.2.16 Follow NRRB Recommendation on Columbia River Impacts****Comment**

The National Remedy Review Board and Contaminated Sediments Technical Advisory Group (the boards) review of the Draft Feasibility Study resulted in the following recommendation<sup>4</sup>: “The boards note that several stakeholder comments indicate that Portland Harbor releases are contaminating the Columbia River downstream of the Site.” “The boards recommend that the decision documents contain a clear explanation as to how the Region believes effective remediation of Portland Harbor sediment should reduce contaminate loading to the Columbia River’s surface water, sediment, and biota.” It is key for the Region to elucidate where contaminants migrate to or be deposited outside the boundaries of the Site, given the Region’s interpretation that the Portland Harbor Site is not largely depositional, but erosional or transitory in nature.

Although we appreciate the Columbia River contaminant loading estimates that were added to the Site Feasibility Study, the proposed plan is grossly inadequate and relies on scouring and off-Site transport of contaminated sediments for the majority of the Site area.

**EPA Response**

See Sections 2.2.10 and 2.17.3 of this responsiveness summary.

**3.2.17 Follow Recommendations of the Confederated Tribes and Bands of the Yakama Nation****Comment**

It is important to the Yakama that the Portland Harbor contamination is cleaned up for all species, the health of the Yakama, our neighbors, and future generations. Contaminant loadings to the Columbia River must be reduced to the greatest extent possible. The ROD must develop a monitoring framework for evaluating contaminant loading to the Columbia River, assess the effects to aquatic biota, and finish delineating the extent of where Portland Harbor contamination has come to be located, as required by CERCLA. The effectiveness of the cleanup is critical to support the recovery of salmon, lamprey, and steelhead (and other species) in these waters and therefore a more comprehensive Alternative G must be implemented.

In addition, any resolution of liability agreement between EPA and the responsible parties must not prevent future actions outside the Portland Harbor Site boundaries where Portland Harbor contamination is transported through or has come to be located.

**EPA Response**

See Sections 2.2.10, 2.16, and 2.17.3 of this responsiveness summary.

### 3.2.18 Explain Why Threshold Criteria Are Not Met

#### Comment

The proposed plan does not adequately demonstrate that the Preferred Alternative (Alternative I) would comply with the two CERCLA threshold requirements: (1) overall protection of human health and the environment and (2) ARARs. 40 CFR § 300.430(f)(1)(i)(A); see also 42 U.S.C. § 9621(d)(2)(A). In addition, it will result in fish consumption advisories for perpetuity.

#### EPA Response

EPA's primary criteria for selection of a Superfund remedy are protection of human health and the environment and compliance with the substantive requirements of federal and state environmental laws. Once these criteria are satisfied, EPA determines the best balance of tradeoffs among the alternatives with respect to balancing criteria, one of which is cost, and modifying criteria, including community acceptance, which includes a wide spectrum of often competing concerns. As stated in ROD Sections 12.1 and 12.2, Alternatives E, F, G and I all meet the two threshold criteria of Overall Protection of Human Health and the Environment and Compliance with ARARs.

### 3.2.19 Address Issues in Meeting Threshold Criteria

#### Comment

Protection of human health and the environment is the statutory standard for cleanup under CERCLA. 42 U.S.C. § 9621(b)(1). Under the discussion of this criterion, interim risk targets for end of cleanup construction were developed by EPA "to specify the level of risk that is ideally achieved through active cleanup" and to determine if alternatives are likely to achieve remedial action objectives that are based on human health or ecological risk. It is then presumed that if interim risk targets are met, then compliance with ARARs would be achieved within a reasonable timeframe after construction through natural recovery processes. However, Alternative I is not anticipated to meet the interim risk-based targets for RAOs 1, 2, and 6, and therefore may not achieve the associated ARARs within a reasonable restoration timeframe. As noted in the Portland Harbor Feasibility Study, for several RAOs "there are no current means to quantitatively assess the effectiveness of the alternative in achieving [preliminary remediation goals] PRGs", for some "there is insufficient information to evaluate" whether the RAO will be achieved, and for others no clear quantitative goal is presented (RAOs 3, 4, 7, 8 and 9). See Table 1 for a summary of interim risk targets.

#### EPA Response

See Sections 2.3 and 2.7 of this responsiveness summary.

### 3.2.20 Address Issues with ARARs

#### Comment

ARARs identified, but not met by PRGs, for the Site include measures of protectiveness of human health and the environment required in the Oregon Hazardous Substance Remedial Action Rules. These include:

- A 1 in 1,000,000 ( $1 \times 10^{-6}$ ) lifetime excess cancer risk for individual carcinogens.
- A 1 in 100,000 ( $1 \times 10^{-5}$ ) cumulative lifetime excess cancer risk for multiple carcinogens.
- A hazard index (HI) of 1 for non-carcinogens.

- Toxic substances may not be introduced above natural background levels in waters of the state in amounts, concentrations, or combinations that may be harmful, may chemically change to harmful forms in the environment, or may accumulate in sediments or bioaccumulate in aquatic life or wildlife to levels that adversely affect public health, safety, or welfare or aquatic life, wildlife, or other designated beneficial uses (OAR 340-041-0033).
- The formation of appreciable bottom or sludge deposits or the formation of any organic or nonorganic deposits deleterious to fish or other aquatic life or injurious to public health, recreation, or industry may not be allowed (OAR 340- 041-0007(11)).

In addition, EPA's proposed plan does not comply with the Clean Water Act. In 2000, the EPA published guidance and recommendations on the use of fish and shellfish consumption advisories in determining attainment of water quality standards and listing impaired waterbodies under Section 303(d) of the Clean Water Act (EPA 2000) 5, which includes the following statement: "EPA generally believes that fish and shellfish consumption advisories and certain shellfish growing area classifications based on waterbody specific information demonstrate impairment of Clean Water Act section 101(a) "fishable" uses. This applies to fish and shellfish consumption advisories and certain shellfish area classifications for all pollutants that constitute potential risks to human health, regardless of the source of the pollutant."

Based on our review of the proposed plan and communications with EPA, it is apparent that fish consumption advisories will be needed at the Site, possibly in-perpetuity. Based on EPA guidance, this advisory would impair the designated use of a fishable lower Willamette and Columbia rivers, and would not comply with ARARs based on state water quality standards.

#### **EPA Response**

Refer LSS Dispute Issue 8 (Appendix A of this document), Sections 2.3.2, 2.4.2, 2.8.1, 2.28, 2.33, 2.34, and 4.1.9 of this responsiveness summary.

### **3.2.21 Avoid Over-Reliance on ICs**

#### **Comment**

The cleanup plan for Portland Harbor under the Preferred Alternative will rely upon ICs, non-engineered measures intended to affect human activities in such a way to prevent or reduce exposure to hazardous substances, to prevent or limit exposure to contaminants for humans, not only during construction activities, but permanently and forever. ICs have no ability to reduce ongoing ecological exposures. ICs will include, but are not limited to, commercial fishing bans, fish and shellfish consumption advisories, signs and fences on adjacent upland areas, enhanced community outreach programs, waterway and land use restrictions through covenants or restricted navigation areas, or other dredging and structural maintenance restrictions in capping area. The reliance on ICs will be for perpetuity.

These ICs are in place of adequate cleanup, do not fully protect human health and the environment, do not fulfill trust obligations, and place the burden of cleanup (or rather inadequate cleanup) on the health of community and environment rather than on the PRPs.

#### **EPA Response**

See Sections 2.3.2, 2.17.6, and 2.28, 2 of this responsiveness summary.

### 3.2.22 Remove All PTW

#### Comment

The proposed plan does not call for complete removal of PTW at Portland Harbor. In addition, dredge depth limits were established for the purpose of cost estimation, but not justified, within the proposed plan. Based on current data and conversation with EPA, we see the greatest potential for significantly high concentrations, mass, and volumes of pollutants to be left in place in sediments adjacent to Arkema and NW Natural Gas.

All PTW should be removed and removal should be as complete as possible. Highly toxic wastes and non-aqueous phase liquids identified in sediments as PTW should be addressed through removal and treatment, as required. We recommend that, once baseline monitoring is complete and vertical delineation of sediment contamination is known, remedy design select complete removal, over capping, wherever possible. Treatment options should ensure that river character, flooding habit, or regional events such as earthquakes and impacts from climate change, do not affect that overall efficacy of the mitigation of these toxic wastes.

#### EPA Response

See Section 2.5 of this responsiveness summary.

### 3.2.23 Address Lack of a Consistent, Conservative Approach and Additional Uncertainties

#### Comment

EPA's evaluation of risk lacks consistent, conservative approaches to evaluating Site risk. In addition, EPA's evaluation of alternatives does not address the underlying uncertainty of success. Many of the methods used for evaluating risk at the Site are not conservative, have a high-level of associated uncertainty which is not adequately addressed in the proposed plan or in the Feasibility Study, and are not in line with current regulations or based on site-specific knowledge.

1. EPA indicates that the development of alternatives is based only on a subset of the COCs present at the Site and under the assumption that addressing a small group of 6 "focused COCs" would address risk associated with all 64 COCs. The development of RALs, interim risk levels, and the estimated duration to achieve RAOs are not based on all Site COCs which under-represents the true risk that will remain after construction and the duration required to achieve RAOs. Although focusing on a subset of COCs may be acceptable for simplifying remedy design, EPA must not lose sight of the fact that there are still 64 COCs contributing to toxicity. The ROD should specify that cleanup levels, other compliance metrics, and future evaluations must estimate the cumulative effects of all Site COCs.
2. PRGs should be developed for all COCs and use maximum exposure assumptions, such as higher fish consumption rates and protective scenarios for Tribal fishers. The Yakama religion and culture teaches us that every fish caught is considered a gift from the provider and is not to be wasted. Therefore, resident fish caught during salmon fishing are also consumed.
  - a. Residual cancer risk and non-cancer HIs for RAO 2 (human consumption of fish and shellfish) were calculated using risk-based PRGs assuming a fish consumption rate based on a national consumption rates (per the BERA) which

- are lower than the regional data available for Oregon and Pacific Northwest-specific fish consumption rates and tribal heritage rates. This may underestimate residual risk and HIs for RAO 2. No tribal member should be put at risk as a result of Portland Harbor contamination. At a minimum, tribal heritage consumption rates<sup>6</sup> should be used for setting cleanup levels.
- b. Residual risk and HIs for RAO 2 were calculated differently for the Site-wide risk estimates (national rate of 142 grams per day) relative to the river-mile risk estimates (using a lower fish consumption rate of 49 grams per day). Documentation within the Feasibility Study does not indicate the appropriateness of this substitution which may result in an underestimation of the residual risk by river-mile. Consistency and conservatism should be used for remedy selection as well as future evaluations and compliance metrics.
  - c. Residual risk and HIs for RAO 2 were calculated using risk-based sediment PRGs protective of fish/shellfish consumption and likely underestimate the total residual risk for all COCs. In the feasibility study, it is stated that “risk-based sediment PRGs protective of fish/shellfish consumption were not developed for arsenic, hexachlorobenzene, mercury, BEHP, pentachlorophenol, and PBDEs because a relationship between fish and/or shellfish tissue and sediment concentrations could not be determined.” Residual risk calculations should estimate the cumulative risk for the Site and include all Site COCs.
3. EPA concedes that “estimating the number of acceptable fish meals at the end of construction is not a precise calculation, but is rather a prediction that has some degree of uncertainty.” However, no discussion of the uncertainty is presented, undermining the validity of these comparisons. A discussion of uncertainty surrounding the fish consumption issue must be included.
  4. The Preferred Alternative does not reduce risk to acceptable levels post-construction. The RALs and interim risk targets are not protective. Allowing for varying RALs across the Site that are orders of magnitude different in concentration and risk does not make sense and is not protective of receptors, especially benthic organisms, organisms utilizing shallow and higher habitat value areas, and beach users. The interim risk targets set for the 9 RAOs are not achievable by Alternative I and/or are unclear. Only one interim risk target (RAO 5, sediments, protection of benthic receptors) is predicted to be met under Alternative I, although it sets the bar low with a limited target of cleaning up only 50 percent of sediments in areas exceeding 10 times the PRGs. Alternative I leaves the majority (83 percent) of the benthic receptors exposed to long-term unacceptable risk (by exceeding one or more PRGs) and they cannot be protected by ICs. Interim risk targets for impacted river bank and groundwater-to-surface water discharges are not clearly stated and these sources are left largely unaddressed in the proposed plan with no clear direction on cleanup goals or plans on the areas not included in Alternative I. Surface water interim risk targets are not defined either. Alternative G RALs should be selected to provide a cleanup that will be more protective post-construction and more likely to achieve longer-term RAOs. The ROD should provide clearer directives and post-cleanup construction goals for all impacted media, including river banks, groundwater plumes and surface water.

5. The feasibility study and the proposed plan provide little, if any, quantifiable support that achievement of the RALs, interim risk targets, and PRGs will allow the final RAOs to be achieved in a reasonable period of time. The level of uncertainty in the ability of any of the alternatives to achieve acceptable risk levels is also never discussed. The uncertainties included in each alternative, in addition to the potential risk that each alternative may not achieve the RAOs in a reasonable period of time, should be clearly discussed.

In order to address the uncertainty in the evaluation of the alternatives and the likelihood that the alternatives achieve RAOs, a conservative and protective approach should be taken for selecting an appropriate alternative. Alternative G with modifications is the feasibility study alternative that best meets these criteria. In addition, the ROD must use a consistent and conservative approach to calculate and select protective interim cleanup goals and final cleanup levels.

### **EPA Response**

Section 3 of the 2016 feasibility study report (USEPA 2016b) discusses the development of the alternatives; evaluation of the alternatives, including how risks are addressed through the proposed RALs and SMAs, is discussed in Section 4. The RALs are concentrations of focused COCs that are meant to cover all COCs posing risk to various receptors at various spatial scales. Thus, the RALs in combination, not individually, are meant to address all COCs, not just the specific focused COC. The RALs, therefore, apply everywhere within the Site where any PRGs are exceeded. The focused COCs were chosen based on their coverage of other COCs. None of the alternatives address all the risks at the Site through construction, with the exception of Alternative H. In the evaluation of alternatives in Section 4, EPA discusses those risks that are not addressed by the construction of the alternatives so that it is clear how much risk was addressed and how much remains to be addressed through MNR. EPA does not “demerit” or characterize this evaluation as a “failure” for any of the alternatives. Further, Alternative F Modified uses a consistent set of RALs outside the navigation channel, taking more active remediation steps to further reduce reliance on MNR over the proposed plan’s Alternative I (USEPA 2016c). See Sections 2.3, 2.6, 2.7, 2.20.3, 2.26.4, 2.27, 2.31, 2.33, and 2.34 of this responsiveness summary.

### **3.2.24 Follow NRRB Recommendations on Risk Level Uncertainty**

#### **Comment**

The boards’ review of the proposed cleanup action resulted in the following important recommendation that was overlooked or not included in the proposed plan, and should be included in the ROD. The levels of risk identified and communicated in documents prepared by the Region omit important information to evaluate uncertainty in some exposure pathways and do not fully address supporting information on the conclusions presented about risk to human health and the environment “...based on the information represented to the boards, some conclusions about risk did not fully communicate the risk characterization (the severity, spatial, or degree of confidence of the risk estimate) and how the remedy components will address Site risks.” “The boards recommend that the decision documents clearly explain how the proposed remedial action would achieve each RAO.”

#### **EPA Response**

EPA has explained in the ROD how the selected remedy would achieve each RAO.

### 3.2.25 Discuss Areas that Will Not Be Cleaned Up

#### Comment

The proposed plan represents a partial cleanup that over relies on natural recovery (primarily dispersion) and will result in the continued release of persistent and bioaccumulative contaminants downstream to the Columbia River. The feasibility study states, “Since much of the Site is erosional or transitional (deposition in some parts of the year and erosional in others) and contaminant mass exists in the river sediment, there is the potential for the contamination to be transported downstream.” The feasibility study also states, “The area where contamination in sediment exceeds the human health PRGs within the Site is approximately 2,190 acres and 30,048 lineal feet of river bank”, which encompasses essentially the entire Site. In addition, the feasibility study and proposed plan confirm that river banks and groundwater plumes are an ongoing source of contamination to the Site. A significant amount of the Site will not be cleaned up and will continue to be a source of contaminated sediments to the downstream Multnomah Channel and Columbia River.

EPA’s remedy should not leave so much of the contamination unaddressed, especially given the significant uncertainties that the PRGs will ever be met. The proposed plan will NOT address:

- 87 percent of the sediment area exceeding human health risk PRGs;
- 67 percent of the contaminated groundwater plume area;
- 83 percent of the sediment area exceeding benthic risk PRGs;
- 35 percent of the length of contaminated river banks;
- and unclear amounts of risk from surface water to receptors and from prey to predators.

These are site-wide post-construction estimates. By compositing site-wide risk, significant areas of the river sediments would present much higher risks, and some lower.

The proposed plan compares alternatives in terms of percent of area or length cleaned up and interim (post-construction) or residual risk. However, the ROD should also provide estimates of the volume and mass of contamination at the Site both before and after cleanup construction. This information will be further refined through the remedial action in phase in order to report on the volume and mass of contamination removed, capped, treated, and left behind for all impacted media.

#### EPA Response

As described in Section 4.1.3 of the feasibility study, the evaluation of overall protection of human health and the environment is based on post construction sediment concentrations and does not consider the mass of contamination removed. Similarly, as described in Section 4.1.5 of the feasibility study, the evaluation of long-term effectiveness and permanence is based on the methodology and assumptions presented in the BHHRA (Kennedy/Jenks 2013) and BERA (Windward 2013). Exposure point concentrations for post-remedial exposures are based on modeled estimates of contaminant concentrations in sediment at the completion of construction.

The feasibility study identified areas for dredging or excavation based on site-specific factors that may limit the effectiveness of containment in-situ treatment, ENR or MNR. Within the navigation channel or future maintenance dredge areas, removal was required to prevent restrictions on navigation. In the intermediate depth areas, a multi-criteria decision matrix was developed as a method to guide the

assignment of capping and dredging technologies, based on specific site characteristics within SMAs. In shallow areas, a mix of shallow removal followed by capping or placement of backfill was utilized to maintain current water depth and thus limit the loss of shallow water aquatic habitat. Alternative F Modified uses a consistent set of RALs outside the navigation channel, taking more active remediation steps to further reduce reliance on MNR over the proposed plan's Alternative I (USEPA 2016c). See also Sections 2.16.1, 2.26.4, and 2.27 of this responsiveness summary.

### 3.2.26 Address Non-Compliance with Short- and Long-Term Risk Goals

#### Comment

EPA's evaluation of short-term or post-construction risk (at 7 years after the start of cleanup) clearly shows that Alternative G would come closer to achieving all interim risk targets (Table 1), would result in lower risk to receptors, and would bring a much larger area of the Site closer to compliance with long-term PRGs and RAOs (Table 2).

As demonstrated by Table 3 below, EPA's proposed plan evaluation of long-term or residual risk at the end of the recovery period or reasonable restoration timeframe (time = 30 years) is very incomplete and unclear. We would argue that the residual risk calculated for RAOs 1, 2 and 6 are also unknown and that the long-term effectiveness of Alternative I, or Alternative G for that matter, is highly uncertain.

Feasibility Study Alternative G with modifications addresses more of the contaminants and remedial action objectives than Alternative I, the proposed cleanup. Within the ROD there should be a transparent process with clearly defined criteria for each type of contaminated media at the Site that will be used to evaluate compliance with interim targets and cleanup levels upon completion of each phase of construction and at the completion of construction activities. This process should be used to evaluate the success of the active cleanup by evaluating the level of risk that remains at the Site upon completion of construction activities. If risk levels and compliance criteria do not comply with stated goals, then contingency efforts should be implemented to ensure that the cleanup moves toward achieving the RAOs by reaching remediation goals and the target residual risks within the stated recovery timeframe. Risk calculations should be conservative and include all COCs and not be limited to compounds where there is a direct correlation between sediment concentration and fish tissue.

#### EPA Response

Refer to LSS Dispute Issue 8 (Appendix A of this document) and Sections 2.6, 2.17, 2.31, 2.33, and 2.34 of this responsiveness summary.

### 3.2.27 Lessen Reliance on MNR

#### Comment

Reliance on MNR is neither appropriate for all assigned site areas, nor is it supported by Site data. The Preferred Alternative (Alternative I) relies on MNR to achieve remedial cleanup levels over 1,876 acres, or 87 percent of the Site. Greater removal of hotspots (lower RALs) as well as additional dredging of targeted higher priority areas is needed.

The selection of MNR for persistent and bioaccumulative chemicals, such as those found at Portland Harbor, is a practice that is widely discouraged in both mainstream science, as well as multiple federal and state guidances. These chemicals will take 100s to 1,000s of years to break down and will continue to affect the ecological food web for much longer than the reasonable restoration timeframe.

Based on a natural recovery evaluation presented in the feasibility study, two of the Sediment Decision Units (SDUs, RM 6NAV and RM 11E) “scored unfavorable for natural recovery”, and over the remainder of the Site “natural recovery processes are neutral.” The evaluation clarifies that this does not indicate that natural recovery is not occurring, “but rather that it is less likely to occur through depositional processes.” The feasibility study information on depositional rates also indicates that the majority of the Site is characterized as either erosional or “transitional.” However, the feasibility study and proposed plan text make conclusions contradictory to the supporting data and evaluations. The feasibility study concludes that the “primary mechanism for MNR is through deposition.” The proposed plan characterizes the Site as increasingly depositional, with the exception of river miles 5 to 7. These broad-sweeping, over-generalized conclusions stated in Feasibility Study and proposed plan about the Portland Harbor Site (or major portions thereof) being a depositional environment, and therefore ideal for MNR, are misleading and not supported by site data or evaluations. They must be corrected.

Since natural recovery for MNR areas of the Site is “less likely to occur through depositional processes” it appears that for the majority of the Site area dispersion is the primary mechanism being relied on for natural recovery. Because of this, contaminants remaining in the areas proposed for MNR (87 percent of the Site) would likely be mobilized and transported downstream and into the Columbia River where they will continue to contribute impacts to Treaty-reserved resources. This non-transparent and unstated expectation that dispersion will be the primary cleanup mechanism for up to 1,876 acres of persistent and bioaccumulative toxicity is irresponsible.

In addition, Alternative I relies on leaving contamination in place, without consideration of ecological use, habitat values or plans for restoration. This does not take into account the need for connectivity, or a linear sequence of non-toxic and restored habitats that provide habitat for resting, feeding and predator avoidance along fish migratory routes throughout the Portland Harbor corridor. For example, Alternative I selects the highest concentration (least protective) RALs at the most downstream end of the Site, an area that encompasses 4 pending restoration projects (PGE Harborton, Linnton Plywood, Miller Creek, and Alder Creek) and Sauvie Island properties that have the potential for higher habitat value. The ROD needs to select a remedy that provides greater protectiveness in areas with higher habitat value and ecological use.

Because a long-term model is not available to predict the time to meet the PRGs, interim targets for risks and hazard indices were established to evaluate the potential for achieving PRGs in a reasonable time frame, which was considered to be 30 years. However, the alternatives that rely most heavily on MNR, including the Preferred Alternative, fail to meet the interim targets for several RAOs, and for other RAOs there is insufficient information to evaluate the likelihood of meeting the remedial cleanup levels. While there is significant uncertainty in the assumption that achieving interim targets post-construction will result in achieving PRGs in a reasonable time frame, it is even more uncertain when the Preferred Alternative would not even result in meeting the interim targets.

One of the factors in determining whether a recovery time frame is reasonable is the uncertainty associated with the time frame prediction. However, the proposed plan does not discuss this uncertainty. The ROD must provide sufficient information to support the statement that 30 years is a reasonable time frame, and that the Preferred Alternative will achieve RAOs within that time frame, including a discussion of uncertainties. It should also include a clearer timeline for pre-construction activities, cleanup construction start and completion, restoration timeframe start and completion, monitoring and ICs, administrative steps, etc.

The ROD should select Alternative G with modifications to expand dredging along heavily used shoreline areas, in shallow water critical habitats, in areas with restoration or mitigation plans, in areas with higher potential for recontamination due to upland sources, and in highly erosional segments. It is more likely to meet interim risk-based targets, significantly reduce the uncertainty associated the remedy's ability to meet remedial objectives, and improve ecological function of the corridor. The proposed plan also needs to include a summary of upland source control effectiveness and how ongoing sources will affect natural recovery.

**EPA Response**

See Sections 2.6, 2.16, 2.21, and 2.31 of this responsiveness summary.

**3.2.28 Address Uncertainty with ENR****Comment**

Enhanced monitored natural recovery using a thin layer (ex. 6 inches +/- of sand with activated carbon) is not a proven remediation technology for the Portland Harbor Site suite or concentrations of COCs and in sediments of similar characteristics. EPA states in the Duwamish ROD responsiveness summary that "The only relatively new technology proposed is the use of activated carbon with ENR, which is why pilot testing will be conducted before determining where and how to implement this technology." We understand that for this reason, ENR pilot studies will be conducted in various plots at the Duwamish Site to better understand that ENR methods (similar to those described for Portland Harbor) will even be an effective technology.

EPA also clarifies that ENR is only appropriate for low scour potential areas with lower contaminant concentrations. However, the Preferred Alternative proposes significant use of ENR in areas with higher scour potential, such as Swan Island Lagoon. In addition, the proposed plan states that monitoring and ICs are typically not required for ENR.

The over reliance on ENR is highly uncertain in its long-term effectiveness and does not support treaty rights. We argue that the need for ENR should be minimized by increasing the dredge footprint, its use should be avoided in higher scour potential and non-depositional areas and in areas of boat traffic, it is only appropriate for low levels of contamination, pilot studies are needed to confirm its effectiveness, and monitoring and ICs are necessary.

**EPA Response**

See Sections 2.6, 2.16, 2.21, and 2.31 of this responsiveness summary.

**3.2.29 Mitigate Nearshore Habitat Impacts****Comment**

The lower Willamette River provides habitat for a variety of animals (invertebrates, fish, birds, mammals, amphibians, reptiles) and aquatic plants which has been designated by the National Marine Fisheries Service as a critical habitat for several threatened or endangered salmon species that migrate through the Site.

The Yakama Nation has treaty-reserved or other fishing rights in areas impacted by the Site. Protection of these rights depends upon the success and permanence of the cleanup implemented. The Preferred Alternative does not adequately address the protection and mitigation of these key habitat areas. Alternative G will provide greater long-term, more permanent, mitigation of contaminated sediments along shorelines, shallows, and higher-value habitat areas and in areas exceeding benthic

criteria to help further a safer, healthier, and more abundant fishery in the lower Willamette River. In addition, ongoing, controlled discharges from groundwater and other upland sources that continue to pollute the river should be addressed immediately, and implementation of remedies should be done in a manner that avoids, minimizes, or compensates for habitat disturbance or loss. Nearshore water quality and habitat must be adequately cleaned up and protected to support a healthy and sustainable fishery.

#### **EPA Response**

See Sections 2.6, 2.8, 2.26.3, 2.26.4, 2.27, and 2.31 of this responsiveness summary.

### **3.2.30 Address Contamination at McCormick and Baxter Superfund Site**

#### **Comment**

Yakama has concerns about the significant amounts of contamination left behind at the McCormick and Baxter Superfund Site, located within the Portland Harbor Superfund Site. We understand that a ROD amendment for McCormick and Baxter will be prepared following the release of the Portland Harbor ROD and look forward to commenting on it. Short-term and long-term performance of the McCormick and Baxter remedy must be adequately monitored and evaluated, and contingencies implemented if warranted. This remedy must be protective of, and not re-contaminate the Portland Harbor cleanup. In addition, the relationship between the McCormick and Baxter Superfund Site and the Portland Harbor Superfund Sites should be more clearly explained in the ROD.

#### **EPA Response**

See Section 2.32.2 of this responsiveness summary.

### **3.2.31 Explain Cost Estimate Inaccuracies**

#### **Comment**

The accuracy of cost estimates associated with the alternatives is of concern. The proposed plan and the Feasibility Study do not present data or provide scientific information that supports the assumption that the Site will be cleaned up within a 30-year time frame. Therefore, in order to accurately compare costs of a selected remedy, the cost for each alternative should incorporate a contingency or probability factor for each alternative that incorporates the possibility of that alternative not reaching cleanup goals within the 30-year time frame. If cleanup goals are not met, additional remedial activities are likely to be required at additional cost. For example, the probability of achieving remedial cleanup levels within a reasonable time frame (estimated at 30 years) using Alternative I is much less than if Alternative G was selected. Therefore, costs associated with implementing Alternative I to reach cleanup goals could be greatly under estimated if additional remediation is needed later. In addition to potential future dredging costs that would be needed in 30 years if RAOs aren't met, there would be other additional costs as well. These repeat costs may be avoided if a more thorough cleanup alternative, such as Alternative G, is selected now to increase the probability of meeting RAOs.

Many of the costs associated with addressing Site issues are not included in the cost evaluation for each of the proposed alternatives and the estimates proposed may not represent actual costs to implement any of the proposed alternatives. For example, contaminated sediment in the navigation channel does not appear to be included in costs estimates. These costs may be deferred to other agencies, like the U.S. Army Corps of Engineers, who will be required to address contaminated sediments during maintenance dredges of the channel and deepening the navigation channel. In

addition, costs associated with mitigating groundwater contamination or recontamination from adjacent upland sources are not included the estimated costs. Cost estimates do not consider efforts to address controlled upland sources impacts river sediments and surface water quality.

### **EPA Response**

See Section 2.22 of this responsiveness summary.

## **3.2.32 Change Heavy Bias On Cost in the Remedy Decision**

### **Comment**

The messaging and politics surrounding cost and effectiveness have been heavily biased and have resulted in a remedy selection that is primarily cost-based. If allowed, EPA's Preferred Alternative I would be a big win and a huge cost savings for the responsible parties (and their insurers), and a huge loss for the health of the community and environment.

Yakama recommends Alternative G with modifications. However, it is disappointing that EPA's feasibility study did not present a suite of alternatives that met CERCLA threshold criteria. Understanding that anything we propose outside the feasibility study would not likely be considered by EPA, we are forced to work with this Alternative G because we feel that it offers the greatest protection of Alternatives A through I. This is a frustrating situation, however, recognizing these limitations we propose that, with the additional modifications offered here-in, Alternative G would help prioritize protection of important environmental resources.

The Lower Willamette Group (LWG) has continuously drawn their lines based on cost and has disrespectfully pressured EPA to choose a more "reasonable" (i.e. cheap) remedy by lobbying intensely, investing in public outreach, and littering the Site Record with one-sided accusations towards EPA, while ignoring their own role in feet dragging and refusing to conduct adequate site investigations. To date the responsible parties have been successful in applying political pressure to EPA, who has repeatedly and inappropriately allowed cost savings to be the dominant or primary remedy selection criteria. The selection of a remedy must not be dismissive of the remaining CERCLA evaluation criteria. EPA and the responsible parties continue to publically broadcast a biased, non-transparent sales-pitch (or "public outreach campaign") highlighting reductions in contamination, but minimizing the facts regarding what contamination, risks, and restrictions will remain. In addition, the responsible parties have included exaggerated scare tactics in their outreach about how cleanup will cause a loss of jobs and that cleanup costs will be transferred to the public. A more fair discussion and evaluation of cost should include the economic benefits from cleanup, which have proven to be substantial elsewhere.

Yakama Nation's recommendation for Alternative G IS reasonable and more protective than Alternative I. For example, the Portland Harbor Site is often compared to the Lower Duwamish Waterway Superfund Site (Duwamish) in Washington. The Portland Harbor Site is 5 times larger by area than the Duwamish Site. However, EPA's Preferred Alternative I, in comparison with the Duwamish ROD, has higher (less protective) PCB RALs and PRGs, would only dredge 1.5 times more sediment, be roughly 2.5 times more expensive, and take the same length of time to implement. Yakama Nation's preferred Alternative G, in comparison with the Duwamish ROD, also has higher PCB RALs and PRGs, but would dredge roughly 5 times more sediment, be roughly 5 times more expensive, would take less than 3 times longer to implement. While this comparison is a far cry from a cost analysis, it highlights the fact that Portland Harbor is a much larger "mega Superfund" site with much greater contamination problems and therefore should be expected to cost more. To reiterate, both

Alternatives I and G would leave behind greater concentrations of contaminants (and resulting risk) than the Duwamish ROD.

Portland Harbor involves over 150 PRPs, is comprised of multiple NPL and non-NPL listed cleanup sites and a large upland source area. If dealt with individually Portland Harbor cleanup would be much more expensive to cleanup than collectively. By cooperatively working together with EPA as one large mega-Site, the responsible parties have the potential for significant cost savings.

In addition, experience has shown that sites that choose cheaper, partial cleanups risk being more expensive in the long run due to factors such as monitoring and O&M expenses over longer recovery periods, lack of natural recovery due to remaining contamination, remedy failure, unresolved contamination liability issues, decreased property value, inability to pursue loans, etc. We have witnessed multiple sites where cleanup had to be supplemented or, in some cases, even redone. One doesn't need to look very far for case studies. For example, recent news coverage on the 2009 Hudson River PCB sediment cleanup indicates post-cleanup monitoring results have spurred the New York State Department of Environmental Conservation (who provided state concurrence on the ROD) to demand additional cleanup.

The responsible parties and their insurers must be called to task. Polluters must pay to restore the health of the river. It is not conscionable (or allowable by CERCLA) to expect that the health of the people and environment must instead pay in order to preserve the profits of the responsible parties.

#### **EPA Response**

See Section 2.22 and 2.23.2 of this responsiveness summary.

### **3.2.33 Provide Detail to Substantiate Remedy Selection Conclusions**

#### **Comment**

The Preferred Alternative (Alternative I) is a very limited or partial cleanup, riddled with uncertainties, inconsistencies, contradictions and uncertainties. However, the feasibility study and proposed plan conclude that Alternative I “would comply with ARARs”, would be protective of human health and the environment, would meet the threshold criteria, and would reduce fish consumption advisories in a reasonable restoration timeframe. The reality is that these conclusions are not supported in the proposed plan or site record. In addition, a decision to choose a cheaper remedy that does not meet threshold requirements cannot be allowed by CERCLA. Among other problems, Alternative I would result in fish consumption advisories on the Lower Willamette River due to contaminants from the Site to be in place after construction of the remedy, after the recovery period of 30-years, and likely forever. The ROD should provide a more detailed evaluation to substantiate remedy selection conclusions, particularly in light of the preferred alternatives' inability to achieve interim targets. Of the action alternatives, a modified Alternative G appears the most likely to achieve interim targets for the greatest number of RAOs, and would therefore be the alternative most likely to comply with ARARs and result in fish consumption advisories more in line with the rest of the Willamette River.

#### **EPA Response**

See Sections 2.6, 2.21, 2.27, and 2.31 of this responsiveness summary.

### 3.2.34 Perform Key Studies

#### Comment

A number of key studies are needed in order to develop an accurate and comprehensive understanding of the Site. This information will be required for remedy design, evaluation of implementation progress, future evaluation of compliance with remedial cleanup levels, and to assess if Site RAOs are achieved.

- **Background and Downstream Baseline and Ongoing Monitoring:** Background concentrations in surface water, sediment, and fish tissue will need to be established upstream of Portland Harbor. Similarly, impacts downstream of the Site should also be assessed and catalogued for comparison, assessing migration of contamination, and evaluating impacts to the Columbia River before and during implementation of the remedy. Monitoring should include the Willamette River, Multnomah Channel, and Columbia River downstream areas.
- **Delineation:** Within Portland Harbor, the distribution and depth of contaminants throughout the Site should be documented for remedy design, among other concerns, in order to ensure that Principal Threat Waste has been successfully treated or removed and to record where contamination will be left behind.
- **Sediment Transport and MNR:** Given the Preferred Alternative relies heavily on MNR (with some ENR), an accurate understanding of the sediment transport regime with Portland Harbor is critical to ensure progress towards remedy goals and that contaminants from the Site are not removed (eroded) from Site sediments only to be transported and deposited in off-site areas downstream in the Columbia River or Multnomah Channel. Currently, no sediment model has been accepted by EPA and the site record, as well as comments made by EPA, indicate that the Site is largely erosional or transitional (at times erosional or depositional depending on river character). If MNR is to be relied upon as a technology for the remedy, there should be empirical data and multiple lines of evidence that support its selection as an appropriate technology to implement at this, including a better understanding of sediment transport. Given the large uncertainties in existing models and an understanding that the Site is “net erosional”, implementation of Alternative G with removal and treatment of more contaminated sediments would ensure a more protective remedy.

#### EPA Response

EPA did not establish any boundaries of waste in the 2016 feasibility study report (USEPA 2016b). EPA developed estimates of various types of waste based on existing information to estimate costs in the feasibility study. The figures show the extent of the evaluation based on various assumptions identified in the feasibility study report. RAL boundaries and cap designs will be established in remedial design. EPA agrees that additional data collection will be required to determine the appropriate design and waste treatment and disposition requirements during remedial design per the ROD decision tree.

EPA used a robust data set provided by LWG, including sediment data collected as recently as 2013 and fish tissue data collected as recently as 2012, to develop the alternatives in the 2016 feasibility study report. The data set includes 2,259 surface and 975 subsurface sediment samples collected during the remedial investigation to characterize the nature and extent of contamination. EPA does not believe there are any errors or omissions in the CSM and that the information used in the 2016 feasibility study report is sufficient to develop and select a remedial alternative. However, EPA

acknowledges that additional data will be collected during remedial design. These data will be used to support establishing remedial action footprints, technology assignments, use restrictions or other ICs, treatment and disposal of dredged material, mitigation requirements, among others. See also Sections 2.17.3 and 2.26 of this responsiveness summary.

### 3.2.35 Implement NRRB Recommendation on Performance Monitoring

#### Comment

The boards' review of the proposed cleanup action resulted in several important recommendations including: "The boards note that at many large contaminated sediment sites, monitoring plays an important role in remedy performance evaluation." "The boards recommend that the Region address and clarify the role of a monitoring plan in the site decision documents." This recommendation appears to have been overlooked or not included in the proposed plan, and should be included in the ROD.

#### EPA Response

See Sections 2.17 and 4.1.3 of this responsiveness summary.

### 3.2.36 Provide Clear Metrics and Monitoring Goals

#### Comment

Monitoring is an invaluable evaluation tool that can be used to assess the completeness of remedy implementation, remedy effectiveness, and the need for contingency actions. The proposed cleanup plan does not clearly define how Site progress will be evaluated and how compliance with regulatory requirements and cleanup objectives will be measured. Without clearly outlining compliance criteria or metrics, a meaningful assessment of the project progress cannot occur. In addition, if the cleanup does not proceed as expected, there is no contingency plan in place to ensure protectiveness for human health and the environment. The ROD must include more adequate detail on how progress and compliance will be measured. More clear and specific information is needed on interim and long-term metrics, how and where they will be monitored or evaluated, timelines, and contingencies.

- **Clear Framework and Metrics:** Although, the specific details of monitoring programs are prescribed in project or action-specific monitoring plans, the overarching goals and program implementation should be made more clear in the ROD. The proposed plan does not, but should, explain how monitoring will be integrated into the cleanup process and clearly define monitoring goals or key elements. In addition, more clear metrics on post-construction, interim, and long-term goals during the recovery period are needed. Within the ROD, each monitoring program should be clear in its goals, process, scaling, metrics, frequency, trigger events, etc. for assessing compliance and meeting project goals.
- **Points of Compliance:** The identification of areas of attainment or points of compliance are a fundamental component in the design and implementation of monitoring programs to evaluate site conditions for setting baseline values, but also for ensuring that data collected throughout the project is consistent and collected as designed for its intended purpose and in such way to be useful in evaluating progress towards the cleanup objectives. Areas of attainment or points of compliance should be clearly defined for all COCs and all impacted media that support achieving the RAOs within the defined compliance period.
- **Upland Sources:** The complexity and size of this Site requires careful management and an understanding of the impacts associated with current, on-going, and potential future releases

from upland sources (groundwater, stormwater, bank erosion, overland flow, and overwater acts); the migration of contaminants from upstream sources; and the removal of contaminants to off-site areas in the Columbia River basin. The integration and planning of effective monitoring programs will be a key element to monitoring cleanup progress and should be included in the remedial plan.

- **Contingency Actions:** Future project decision documents should identify contingencies triggered by threshold criteria, identified action, implementation timeframe.
- **Yakama's Role:** Yakama has significant concerns about monitoring and expects to participate in development of monitoring strategies for Portland Harbor.
- **Example Monitoring Needs by Media Type:** Examples of important monitoring programs and target media are summarized in the table below. For example, in-river groundwater plumes should be delineated and monitored in order to evaluate areas of potential recontamination concern and to assess that source control measures are implemented and effective. Fish tissue monitoring will be essential to evaluate progress towards removing Site-specific fish consumption advisories and other ICs that limit the beneficial use at the Site. Surface water quality, upstream loadings, and the downstream migration of contaminants will be fundamental in evaluating impacts from the Site to the Columbia River, impacts from implementation of the remedy, and compliance with ARARs.

#### **EPA Response**

See Sections 2.17 and 4.1.3 of this responsiveness summary.

### **3.2.37 Provide Acceptance Criteria for Caps and Daily Cover**

#### **Comment**

The ROD must outline acceptance criteria that meet the PRGs, applicable ARARs for all contaminants, and construction quality criteria for imported cap and daily cover materials.

#### **EPA Response**

Final cleanup levels for all COCs and all applicable ARARs (including action specific) are contained in the ROD. Construction quality assurance criteria for cap/residual layer placement will be identified during the remedial design phase of the project.

### **3.2.38 Specify PCB Analysis Methodology**

#### **Comment**

PCB criteria (RALs and PRGs) are stated in the proposed plan; however, the methodology is not specified. The ROD must specify that for all media PCB analysis should include all congeners, and not simply aroclors. The aroclor analysis does not include all congeners, has higher detection limits and therefore is under-representative of risk. The advantages of congener analysis are that data are more representative of site conditions and therefore more useful for understanding toxicity, risk, weathering, biotransformation, causation, as well as fingerprinting sources. We understand there are reasons to include aroclor analysis such as outdated Clean Water Act water quality criteria. This is an example of how science has evolved and improved, but regulations have not kept up. If aroclor data are needed for certain media, it should be in addition to congener analysis and not in place of it.

**EPA Response**

Refer to LSS Dispute Issue 6 (Appendix A of this document) of this responsiveness summary.

**3.2.39 Conduct an Environmental Justice Analysis****Comment**

An environmental justice analysis of the Portland Harbor Site has been completely overlooked (see 2014 Duwamish ROD, sections 6.1, 10.3.3, and 13.2.8) and should be conducted.

**EPA Response**

See Section 2.35 of this responsiveness summary.

**3.2.40 Use Upstream to Downstream Cleanup Sequence****Comment**

In past conversations with EPA, management indicated that cleanup would be sequenced in the order in which responsible parties were willing to cooperate. We strongly urge remedy implementation to be sequenced so that dredging is conducted starting at the upstream end and working downstream in order to prevent recontamination.

**EPA Response**

Where possible, remedial action would be sequenced by area, generally moving from upstream to downstream where possible, capping/dredging contaminated sediment, before moving on to the next area. The actual remedial action sequencing would be developed during remedial design phase of the project.

**3.2.41 Clarify Use of Waivers****Comment**

The ROD must clarify how, under what circumstances, and at what point in time a waiver of ARARs may be considered. For example, a use attainability analysis or other evaluation supporting a technical impracticability waiver.

**EPA Response**

See Section 2.3 of this responsiveness summary.

**3.2.42 Follow NRRB Recommendation to Define Recovery Timeframe****Comment**

The boards' review of the proposed cleanup action resulted in several important recommendations that were overlooked or not included in the proposed plan, and should be included in the ROD.

The board recommended that EPA Region 10 (the Region) "clearly communicate to the local community and other stakeholders the anticipated timeframe needed to carry out the cleanup's active phases, including the time needed to undertake the remedial design and the remedial action phases, and to clearly describe the anticipated recovery time needed after completion of the selected remedy's active phase, such time as the time aquatic receptor tissues will need to recover."

**EPA Response**

See ROD Section 14.2 and responsiveness summary Section 2.21.

### 3.2.43 Clarify the Five-Year Review Schedule

#### Comment

The ROD must clarify the schedule for five-year reviews. For example, we understand these reviews can vary beginning 5 years after construction starts or ends. In the case of Portland Harbor, a construction period of 7 years or longer justifies the need for a more formal evaluation(s) during construction to help understand how effective the cleanup is and, if needed, adjust the cleanup design or construction strategy. Five-year reviews should include an evaluation of the need to implement new sediment remediation technologies to assist in the further reduction of Contaminants of Concern in sediments, surface water and/or fish tissue (ex. Duwamish 2014 MOA).

#### EPA Response

Following construction, there will be long-term monitoring until the cleanup goals are achieved and beyond. Monitoring will be conducted for pre-remedial design and remedial design. In addition, the first five-year review will take place five years after the start of construction. Also, see Section 2.17.3 of this responsiveness summary.

### 3.2.44 Provide a Contingency Plan

#### Comment

Given all the uncertainties, the remedy selected should include appropriate contingency measures. EPA's Contaminated Sediment Remediation Guidance for Hazardous Waste Sites<sup>10</sup> states that contingency measures should be included as part of a MNR remedy when there is significant uncertainty that the remedial action objectives will be achieved within the predicted time frame. For example, new technologies can be incorporated into an explanation of significant difference or ROD amendment after the ROD is issued, based on five-year reviews. EPA has authority to alter the remedy even if the change or associated cost increase differs substantially from the ROD. See NCP at 40 CFR § 300.435(c)(2).

In light of the multiple layers of uncertainties associated with Alternative I, the ROD should identify the contingencies that will be implemented if an alternative is not achieving the interim risk targets and not recovering towards RAOs after implementation at an adequate rate. This should be included in what is to be provided to the public for review, along with a clear timeline and criteria for the decision to move forward with a contingency plan. Additional contingencies could include increased dredging, in-situ remediation, ENR, source control, new remediation technologies, etc. We suggest a timeline of 10 years post cleanup construction (ex. Duwamish ROD) for making decisions regarding the need for contingencies. Robust monitoring would be needed to evaluate site conditions and recovery rates.

#### EPA Response

See Section 2.17 of this responsiveness summary.

### 3.2.45 Provide Rationale for Using RM 16 as Background

#### Comment

Background sediment samples collected at river mile 16 (RM 16) are located in close proximity to a known PCB source (a waste water treatment plant per conversation with EPA). DEQ has also summarized data gaps and source control needs for inputs upgradient of the Site. EPA has stated that they will continue to pursue evaluation of anthropogenic background values at RM 16, despite influence by known and ongoing sources, yet has failed to provide information on the problems and

uncertainties associated with background values in the proposed plan. The ROD must include a transparent written and visual description of upgradient sources and rationale for their decision to continue using RM 16 to establish background based cleanup levels. Background anthropogenic sources should also be addressed in regional source control efforts.

#### **EPA Response**

See Section 2.17.6 of this responsiveness summary.

### **3.2.46 Include NRRB Recommendation for Source Control Management in ROD**

#### **Comment**

The boards' review of the proposed cleanup action resulted in several important recommendations<sup>11</sup> that were overlooked or not included in the proposed plan, and should be included in the ROD. "The boards recommend that the Region work with the state to establish a timeline for upland source control of contaminants to the Willamette River so that upland remediation can take place before or at the same time as in-river treatment and dredging/capping of river sediment. The boards further recommend that the Region work with the state to ensure that surface water/groundwater discharged into the river from all of the more than 100 contaminated upland locations meet the relevant maximum contaminant levels. In addition, the boards recommend that the Region consider including in its decision documents clear criteria for evaluating when source control is sufficient to start remedial action, and that EPA continue to work with the state to ensure that source control actions are completed in a timely fashion. The boards also recommend that the Region consider whether undertaking source control actions using CERCLA or other federal authorities might be appropriate to ensure the EPA-selected remedial action's integrity."

#### **EPA Response**

The selected remedy relies on the adequacy of DEQ's source control to achieve cleanup levels and RAOs and to prevent recontamination of the Site. It is EPA's expectation that DEQ's upland source control actions will adequately address groundwater contamination (the plumes). The cleanup of known or potentially contaminated upland sites is tracked in DEQ's Environmental Cleanup Site Information database, which is available online at <http://www.deq.state.or.us/lq/ECSI/ecsi.htm>, and source control efforts are summarized in DEQ's Portland Harbor Upland Source Control Milestone and Summary Report (<http://www.deq.state.or.us/lq/cu/nwr/PortlandHarbor/jointsource.htm>). Source control continues to be a separate requirement for this project. EPA is actively participating with DEQ on source control efforts. Also, please see Section 2.27 of this responsiveness summary.

### **3.2.47 Address Upland Source Control Needs**

#### **Comment**

Upland Source Control remains uncontrolled without a clear plan on when it will be implemented. Within the ROD, EPA must provide greater transparency and directives regarding the progress and effectiveness of upland controls, as well as a summary of data gaps, source control needs, and strategy.

Source control is jointly tackled by multiple agencies including EPA, DEQ, and City of Portland, with the 2005 Portland Harbor Joint Source Control Strategy document<sup>12</sup> guiding efforts. This plan should be updated as soon as possible, and should continue to be updated periodically. New information and changes in sources have undoubtedly occurred in the past 11 years, and the prioritization of sites, as well as the source control framework and strategy needs to be re-evaluated.

The most recent and comprehensive source control summary was prepared by DEQ in 2016. Although progress has been made, this document has identified an overwhelming number of unresolved data gaps and source control needs surrounding the Site, as well as upstream. The DEQ implementation of upland source control remedies is intended to eliminate, control or minimize all sources of contaminants from on-going and future discharges of stormwater, groundwater, soil erosion, and other direct sources to the Portland Harbor Site. With respect to upland cleanup sites, DEQ's management of Portland Harbor is currently primarily a voluntary process and many of the cleanups appear to be interim (partial cleanups), rather than final actions. DEQ does not seem to be effectively utilizing its removal authority to require immediate design and implementation of permanent source control measures prior to implementation of the remedy at the Site. Many sites have documented uncontrolled sources, investigations only partially completed, or property owners who have never responded to site assessment requests.

Currently, there are numerous upland sites with moderate or high recontamination potential for the Portland Harbor cleanup. All of the sites listed in the table below have current, on-going, uncontrolled releases to the lower Willamette River. In addition to these sites, DEQ has identified numerous facilities or areas where releases are suspected but investigations have not been completed.

If the DEQ cleanup program remains voluntary and control of these sites is not completed once the sediment remedy is implemented, the risk for recontamination of sediments through unmitigated groundwater, stormwater, and other direct discharges to the river remains high. The ROD needs to provide a clear timeline and strategy for how EPA and the state will apply their collective authorities at these state-lead upland suspected or confirmed cleanup sites that impact Portland Harbor where investigations and cleanups are not moving forward adequately (or not at all in some cases). There are also several recalcitrant federal cleanup sites where EPA needs to become more involved (ex. US Moorings and US Navy).

The proposed plan provides very little information on cleanup of upland river bank and groundwater sources to Portland Harbor sediments. It appears, but is not completely clear, that the proposed plan may be deferring this work to the state. However, in their 2016 summary report, DEQ has deferred the selection of river bank erosion source control measures, mitigation designs, permitting, and overall implementation to EPA. The ROD needs to require a more comprehensive cleanup of river bank and groundwater plume contamination, as well as provide transparency and clarity on how EPA and the state will address these media and how ROD criteria will apply to these sources. Baseline monitoring should include an investigation of areas with suspected contamination that have not been adequately investigated to inform cleanup design.

EPA needs to clarify how the ROD and other specific efforts will address the numerous other upland contaminant source control needs and data gaps that need to be addressed, including floodplain soils, stormwater discharges, groundwater seeps, combined sewer overflow (CSOs), railroads, and federal, city, DOT, port and county facilities or discharges not necessarily under DEQ purview. Also of concern is the fact that configurations of the Big Pipe construction make it difficult to trace pollutant load from a specific source area to a discharge point.

There has been no commitment from EPA to take enforcement actions or to use its authority to compel cleanups for upland sites that currently impact the quality of water and sediment in Portland Harbor. The proposed plan does not address the transmission of contaminants from sites where source control actions are not completed by DEQ prior to the implementation of the Portland Harbor

cleanup. If source controls are not implemented, continuing transport of contaminants will diminish the overall effectiveness of any remedy EPA implements.

The ROD should identify milestones for the upland source control work based on the in-river remediation schedule that triggers intervention by EPA in the upland source control remediation efforts. This timeframe should be identified so that EPA has adequate time to implement actions to address source control issues prior to adjacent or downstream in-river work.

#### **EPA Response**

Refer to Section 3.2.46 of this responsiveness summary.

### **3.2.48 Prevent Recontamination**

#### **Comment**

Based on the population density and types of activities surrounding Portland Harbor, as well as upstream, future re-contamination is a certainty. The ROD needs to address how recontamination will be handled; clarify roles of federal, state, and local programs in addressing recontamination; and begin developing the framework for a monitoring program that will inform source control efforts on where recontamination is coming from (ex. upland sources, in-river transport of sediments, etc.). EPA has a continued role in source control and prevention and cleanup of recontamination and cannot shift this responsibility entirely to the State of Oregon.

#### **EPA Response**

Please see Sections 2.17, 2.27, 2.37, and 4.1.10. Per the ROD decision tree and design elements, river banks within SMAs will be evaluated for their recontamination potential. In addition, river banks outside of the SMAs will be evaluated by DEQ for recontamination potential and potential action. Refer also to ROD Section 14.2.5 and Sections 2.26.2, 2.26.3, 2.26.4, and 4.2.10 of this responsiveness summary.

### **3.2.49 Develop a Regional Plan for Addressing Contaminants**

#### **Comment**

The Portland Harbor cleanup should be included in a more comprehensive approach to addressing the contaminants in the Willamette River watershed by implementing a coordinated multi-program effort using EPA, State of Oregon, and local authorities. The cleanup at Portland Harbor is a long-term investment in community and ecological health. In order to sustain a successful remedy that is protective of human health and the environment, EPA should implement a comprehensive and integrated cleanup approach that addresses the complexity of the contaminant challenges. This will require participation of coordinated programs to identify, plan, implement, and monitor activities necessary to ensure compliance with environmental laws and regulations. This is of particular importance to ensure that sources within and upstream of Portland Harbor do not cause recontamination of the Site or otherwise diminish the efforts to remediate Portland Harbor.

The ROD should include a means for assuring that these sources will be cleaned up. In addition to the ROD, on a region-wide scale additional use of existing Clean Water Act authorities for TMDLs, discharge permits, and enforcement actions must be considered. For example:

- Develop an integrated watershed management plan with subwatershed approaches to return the Willamette River to a status of health.

- Particularly focus is needed for contaminants such as DDT, DDE, PCBs, and PAHs that are causing 303(d) impairment of water and for which currently there is neither a TMDL underway nor a process to delist.
- Implement a Willamette River basin-wide TMDL.
- As a pre-cursor to a TMDL, consider the benefits of implementing a Willamette River basin-wide Pollution Loading Analysis to help evaluate the cumulative effects of pollution, aid in identifying sources and their relative contributions, and help prioritize upland source control efforts (ex. Green-Duwamish Watershed pollution loading analysis).
- Consider updating state NPDES permitting requirements. For example, see recent Washington Department of Ecology proposal to modify the Phase I Municipal Stormwater Permit to include requirements for Seattle to adaptively manage their municipal stormwater discharges to the Lower Duwamish Waterway, as well as their updated Industrial Stormwater General Permit (ex. more frequent cleaning and sampling of process lines).
- Revisit the 2009 EPA study<sup>14</sup> recommending the following for the Columbia River Basin, which includes the Willamette River basin: (1) expand toxics reduction activities; (2) identify, inventory, and characterize the sources of toxics in the basin; (3 & 4) develop regional, multi-agency long-term monitoring and research programs; (5) develop a data management system that will allow us to share information on toxics in the basin; and (6) increase public education about the toxics problems and resource needs.

EPA needs to make a commitment, on a multi-program level, to ensure the long-term success of the Portland Harbor cleanup, reduce contaminant inputs to the Willamette River, prevent Site re-contamination, and restore the health of the Willamette River to its beneficial uses. This commitment must involve collaboration with state and local partners, tribes, and public interests. The Yakama Nation expects to be an active participant in the development of a regional plan.

### **EPA Response**

In addition to addressing contamination at the Site, EPA recognizes that Portland Harbor is only a small part of the greater Willamette River watershed system. EPA anticipates working with DEQ to develop a comprehensive strategy for identifying and addressing additional sources of contamination to the selected remedy. This effort will include consultation and coordination with tribes, the community, local government, and other interested parties. Refer to LWG Dispute Issue 1g (Appendix A of this document).

EPA will continue the working relationship established under the 2001 MOU for tribal government input to ensure that their concerns and interests are considered whenever EPA actions may affect tribal interests.

### **3.2.50 Do Not Use Roosevelt Landfill**

#### **Comment**

Yakama Nation requests that EPA consider landfill options outside of Yakama Ceded Lands for disposal of wastes from the Site. The feasibility study indicates that other acceptable landfill options are available which include the Columbia Ridge Landfill (Subtitle D) and Chemical Waste Management (Subtitle C) in Arlington, Oregon. These landfills have adequate capacity; available rail transport, and accept wet waste (Columbia Ridge).

**EPA Response**

EPA will consider the potential use of any permitted facility (Subtitle D or C) proposed for disposal of dredged material during remedy implementation.

For cost estimating purposes only, the 2016 feasibility study report (USEPA 2016b) assumed Roosevelt Landfill as a representative Subtitle D facility used for disposal of contaminated sediments. Since it is anticipated that responsible parties will implement the remedy, those parties will propose disposal facilities for EPA's approval.

**3.2.51 Do Not Use a CDF****Comment**

Yakama Nation opposes the use of a CDF at the Portland Harbor Site because high-level contaminated sediments should be permanently removed from the river. The construction of a CDF would destroy an estimated 14-acres of critical, high-value habitat and poses an unnecessary risk for future contaminant releases. Although modeling of the proposed CDF shows concentrations of COCs released from the CDF will be below water quality criteria, the model shows releases of COCs will continue to the Willamette River in perpetuity which may result in further impacts. This seems counter-productive to the goal of cleaning up the Site and achieving the RAOs.

The CDF modeling excludes modeling of the lighter fraction COCs since as stated in the feasibility study, "heavier, more hydrophobic and recalcitrant compounds are expected to have the greatest effect on long-term water quality issues in CDFs." Lighter fractions of the COCs should be modeled since the short-term water quality issues could be greatly affected. In addition, an evaluation of existing technologies that could be implemented that would eliminate the leaching of COCs from the CDF into the Willamette River is lacking and should be discussed. The analysis of the use of the CDF should also include the possible future effects on releases from construction and operation, global warming, flooding, and potential earthquake hazards.

**EPA Response**

Refer to Section 2.14.1 of this responsiveness summary.

**3.3 Confederated Tribes of the Grand Ronde****3.3.1 Select Alternative G****Comment**

Of primary concern is that the proposed plan is not sufficiently protective of human health and the environment. Alternative G, while still insufficient in some respects from Grand Ronde's viewpoint, would be far more effective in protecting human health and the environment than the alternative EPA advances in the proposed plan (Alternative I)

**EPA Response**

Refer Five Tribes' comment responses (3.1.12, 3.1.23, 3.1,25, and 3.1.26).

**3.3.2 Continue Engagement with Tribe to Ensure Protectiveness****Comment**

Grand Ronde's first priority in terms of the Portland Harbor cleanup is the health and safety of all of its Tribal members. It is unacceptable to the Tribe that Tribal members are at increased risk of harmful effects from contaminants when they eat their traditional foods. The remedy must be sufficiently

protective of human health and the environment, including Tribal members and Tribal cultural resources. As a consulting sovereign nation and a Trustee of natural resources at Portland Harbor, Grand Ronde requests the continued engagement with the Tribe in the cleanup past the ROD and throughout all remedial design, operation, and monitoring phases. The end result of the Portland Harbor cleanup should be that the lower Willamette River supports Tribal cultural resources, and that Tribal members can use and consume those resources at traditional levels without risk of ill effects from exposure to Portland Harbor contamination.

### **EPA Response**

EPA considered numerous factors, such as tribal fish consumption rates and the effects of contamination at the Site on treaty-protected resources, to develop remedial alternatives for the Site. Once implemented, the cleanup will improve fish habitat and help further the tribes' rights to fish. The scope of the CERCLA action is restricted to approximately 10 miles of the Willamette River, but upstream of the Site, background levels of PCBs from "clean" areas exceed the acceptable range based on conservative risk estimates, meaning that even with a more stringent remedy proposed fish advisories would likely remain in effect following the cleanup. Refer to response to comment on background and fish advisories.

Throughout the remedial investigation/feasibility study process, EPA has fostered meaningful engagement with the MOU partner tribes and has encouraged and facilitated Tribal involvement. Consistent with EPA's Policy on Consultation and Coordination with Indian Tribes, EPA also held consultation meetings at tribal council locations from January 12 through February 4, 2016 and from July 19 through July 26, 2016, during the public comment period on the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c). In addition, representatives for the Confederated Tribes and Bands of the Yakama Nation met with Administrator McCarthy on July 26, 2016 in Washington, D.C. A summary of the consultation meetings, along with any written materials provided, are in the Administrative Record.

The consultation process also included discussions on treaty rights, as directed by the February 2016 Guidance for Discussing Tribal Treaty Rights, which was issued in order to enhance consultations in situations where tribal treaty rights may be affected by a proposed EPA action. including conducting formal Tribal consultations. Government-to-government consultations occurred in January and February of 2016 in anticipation of the proposed plan.<sup>5</sup> EPA will continue this working relationship for tribal input under the MOU and EPA's Policy on Consultation and Coordination with Indian Tribes, to ensure that tribal concerns and interests are considered whenever EPA actions may affect tribal communities – both related to treaty rights and other impacts. The ROD includes language regarding tribal coordination and consultation and community involvement in all activities post ROD.

The Site is complex and the remedy preferred by EPA to perform an effective cleanup under these complexities will require an ongoing partnership and collective input from both the state and the tribes in communication with EPA, for critical decisions made throughout the implementation of the in-river cleanup.

### 3.3.3 Review Attached Documents Supporting Alternative G

#### Comment

Please review the attached technical recommendations and comments showing why Grand Ronde must advocate for, and EPA must select, Alternative G with some additional improvements including assurance that the remedy components can withstand severe flooding and a Cascadia Subduction Earthquake.

#### EPA Response

Please see Sections 2.6, 2.19, and 2.31 of this responsiveness summary.

## 3.4 Confederated Tribes of Siletz Indians

### 3.4.1 Address the Comments Submitted by the Five Tribes

#### Comment

The Confederated Tribes of Siletz Indians (Siletz Tribe) fully joins in the attached Five Tribes' Comments on EPA's proposed plan for the Site. The Siletz Tribe writes separately to emphasize the importance to its members of a robust and sufficiently protective remediation of the Site.

#### EPA Response

Comment noted.

## 3.5 Confederated Tribes of the Warm Springs Reservation

### 3.5.1 Select a More Aggressive Alternative

#### Comment

None of the alternatives in the proposed plan and feasibility study meet our vision for cleanup of the Site. Alternative I, the preferred alternative identified in the proposed plan, is concerning because it does not give us confidence environmental and human health risks will be eliminated post 10-years of construction. We do however acknowledge that dredging is not a viable option in all locations and therefore other remedies will need to be employed. This alternative is highly reliant on passive remedial technologies, primarily MNR, ENR, and capping. All of which have associated risks and leave contaminants in the sediment.

#### EPA Response

Please see Sections 3.1.3 and 3.1.33 of this responsiveness summary.

### 3.5.2 Do Not Use MNR/ENR in the Most Contaminated Areas

#### Comment

The application of MNR and ENR does not remove all contamination from the sediments; the performance and outcome is unknown; the dynamic nature of the Willamette River particularly in the face of climate change is not well understood; and long-term costs associate with monitoring these applications for perpetuity exist. The assumption that natural recovery will occur by the movement of clean sediments mixing with contaminated substrate leaves an unacceptable risk particularly since modeling efforts in the Willamette were unable to confidently predict particle movements. Both MNR and ENR should only be used in areas that are known to be depositional or considered neutral. The designation of depositional and erosive area is not always clear in the proposed plan and feasibility

study; therefore, in the remedial design, new data may need to be collected and new technologies assigned as appropriate. In the most contaminated areas, MNR and ENR should not be considered.

#### **EPA Response**

Please see Sections 2.16.1 and 2.17.3 of this responsiveness summary.

### **3.5.3 Use a Minimum Cap Thickness of 16 Inches Instead of 12 Inches**

#### **Comment**

A significant number of sites have been identified for capping. Capping assumes that partial removal of contaminated sediments can then be topped with various materials to create a protective cover. It will be important to ensure that the appropriate caps are assigned based on the contaminants present, for example, a reactive cap may not be appropriate in areas with metals present. Caps that are predominantly sand should incorporate organic materials to improve their ecological function. The Willamette River is home to the largest individual run of lamprey in the Columbia River Basin. Lamprey are reliant on finding burrowing habitats, and may select areas where capping has been implemented. The addition of organics will not only improve the function of caps but also improve burrowing locations. However, we are concerned that the depths of the caps are not adequate for lamprey. Currently, the proposed cap thickness is 12 inches. We recommend a minimum, total cap thickness of 16 inches to ensure lamprey are not burrowing into contaminated sediments.

#### **EPA Response**

Please see Section 3.1.37 of this responsiveness summary.

### **3.5.4 Clarify Plans for Addressing Groundwater**

#### **Comment**

It appears in Alternative I, only 33 percent of the groundwater plume will be addressed and remediation plans are only available for 65 percent of the upland areas. This is of concern since these are both pathways for contamination to reach the Site. The proposed plan describes the working relationship and responsibilities between DEQ and EPA within the Site. With few exceptions it is the responsibility of DEQ to address the groundwater plume and upland areas. It is unclear the role of EPA if remedial designs do not adequately address contaminants entering the waterway. Without plans to address these, continued and re-contamination is possible.

#### **EPA Response**

Please see Section 2.27 of this responsiveness summary.

### **3.5.5 Ensure ICs are Used**

#### **Comment**

Alternative I require majority of the Site to have long-term monitoring, maintenance and a guarantee of funding for perpetuity to ensure their effectiveness. It is important that post de-listing that the commitment of funding and maintenance continues. There are no assurances that MNR, ENR, and capping will perform as expected since contaminated sediments are not being removed completely and there is no long-term information available that suggests their success. Because many of the most toxic contaminants have long aquatic half-lives and will remain in the substrate, ICs will continue to be necessary including fish consumption guidelines and are likely to restrict access to waterways and land use.

**EPA Response**

Please see Section 2.28.1 of this responsiveness summary.

**3.5.6 Reconsider Alternative G****Comment**

Alternative G is the only defensible option within the proposed plan and feasibility study; however, it still poses risk. Alternative G is the only alternative that meets EPA threshold criteria of “Overall Protection of Human Health and the Environment” and “Compliance with ARARs”.

Alternative G removes the most contaminants. Dredging to remove all contaminated materials should be the largest portion of remedy. Dredging should be considered in all locations over MNR, ENR, and capping; even in nearshore areas. Where non-aqueous state liquids (NAPLs) and PTW are present, dredging should be the technology of choice to eliminate the risk of cap breaching and re-contamination. Further, we are concerned that in areas with the presence NAPLs and PTW, these contaminants, may move through sediments and cause re-contamination. In locations where nearshore structures are present, and dredging does not appear to be an applicable technique, removal of the structure(s) should be considered and completed to the extent practicable. While dredging is the most costly solution, it eliminates the long-term costs associated with MNR, ENR, and caps for perpetuity and eliminates the need for ICs. Additionally, ICs are difficult to enforce and could compromise human health and the environment post-cleanup and de-listing of the Site. Removal of contaminated substrate has the highest environmental, human health, and economic benefit.

**EPA Response**

Please see Sections 3.1.8, 3.1.12, 3.1.23, 3.1.46, and 3.1.61 of this responsiveness summary.

**3.5.7 Ensure Any CDF Is Secure in Perpetuity****Comment**

For materials removed during dredging, a confined disposal facility (CDF) could be developed on-site but would need assurances that the containment of contaminated materials would be secured for perpetuity. An off-site CDF also could present risks to both the Willamette and Columbia rivers. To determine a CDF location, EPA should conduct a risk analysis that takes into account: the permanence of containing contaminated sediments; the potential risks or benefits to each location; and characterization of the risk associated with the transport of these materials to the Willamette, Columbia and adjacent communities.

**EPA Response**

Please see Section 3.1.41 of this responsiveness summary.

**3.5.8 Update, Advertise, and Better Educate the Public on Fish Advisories****Comment**

Without full removal of all contaminants that affect human health, fish consumption guidelines will not be eliminated for all portions of the consumer population. During the remedial design, Guidelines need to be updated to protect the tribal demographic and include the entire fish not just fillets. Additionally, the fish consumption guidelines need to include migratory species, particularly lamprey and sturgeon, which are likely to spend multiple years within the Site and are known to accumulate toxins based on high lipid content and species longevity. Because fish consumption guidelines are

hard to enforce, greater outreach and education need to be completed including notices in tribal media and in-community presentations.

#### **EPA Response**

Please see Section 3.1.49 of this responsiveness summary.

### **3.5.9 Commit to Engaging the Tribe throughout Remediation**

#### **Comment**

Continued commitment to communication with the Tribe is essential through the remedial phase. These conversations should include continued engagement through the Trustee Council. This includes any request by the potentially responsible parties to deviate or request flexibility from assigned remedies. We appreciate the government-to-government engagement to date and encourage it to continue with more frequency. We would, however, like to remind EPA that trust obligation includes providing a tribal consultation and ability to comment prior to documents being released to the public for review and comment.

#### **EPA Response**

Please see Sections 3.1.55, 3.1.87, and 3.3.2 of this responsiveness summary.

### **3.5.10 Hold PRPs Accountable and Remedy Damages to Tribal Resources**

#### **Comment**

We acknowledge the large effort that has gone into the development of the proposed plan and feasibility study. Further, specific comments are attached in a combined memo from the five MOU signing tribal trustees (The Confederated Tribes of the Warm Springs Reservation of Oregon, The Confederated Tribes of the Umatilla Indian Reservation, the Nez Perce Tribe, the Confederated Tribes of Siletz Indians, and Confederated Tribes of the Grand Ronde Community of Oregon). As proposed, preferred Alternative I, leans toward reduced costs for polluters without a guarantee that cleanup will be successful in the timeframe needed. Alternative G should not have been rejected based on cost to polluters and the period of construction. It appears that the criteria used to determine the preferred alternative is bias toward choosing a mid-level cleanup option by giving deference to an option that has short-term impacts during the construction phase.

The United States has a treaty trust obligation to restore the Site and habitats to protect human health and promote a naturally functioning environment where traditional practices continue, knowledge can be passed to future generations and provide healthy, harvestable populations of culturally significant species for perpetuity.

We expect EPA to hold the responsible parties accountable and use enforcement as necessary to remedy damages to tribal resources by:

- Completing cleanup in a reasonable timeline of 10 years post-construction;
- Removal of contaminated sediments by dredging at all practicable locations with less reliance on MNR, ENR, and capping;
- Elimination of fish consumption guidelines for all fishes within the Portland Harbor;
- Development of a monitoring plan with appropriate deliverables and timelines;

- Commitment from the United States government that post de-listing of the Site, monitoring, maintenance and associate funding will continue to ensure the permanence of remedial actions; and,
- Continued communication, at all levels, with the Warm Springs Tribe.
- Threats to treaty reserved rights and human health need be taken into account during the development of the Record of Decision and remedial designs.

#### **EPA Response**

Please see Sections 3.1.2, 3.1.12, 3.1.26, 3.1.46, 3.1.55, and 3.1.86 of this responsiveness summary.

### **3.6.1 Nez Perce Tribe**

#### **3.6.1 Let Long-Term Protection of Human Health and the Environment Drive the Remedy Decision**

##### **Comment**

The Tribe has an interest in ensuring that the cleanup of the lower Willamette River is based in the best available science in order to achieve lasting protections of ecological and human health. The Tribe strongly believes that long-term protection of human health and the environment should drive the remedy decision. We have communicated this position to EPA several times over the course of our partnership and during government-to-government consultation. Unfortunately, we feel that EPA's proposed plan fails to ensure the long-term recovery of the lower Willamette River to conditions that support natural resources and the continuation of our cultural heritage and activities that rely upon the river and its habitats

##### **EPA Response**

EPA has revised its preferred alternative to Alternative F Modified. Alternative F Modified relies on application of the same remedial action levels (F RALs) throughout the Site with the exception of the navigation channel where the remedy will target PTW and sediment contamination exceeding the Alternative B RALs. Due to differences in water depth, sediment transport potential and exposure potential the use of higher RALs in the navigation channel is justified. This modification will address the majority of the comments as it does take more active steps to ensure a faster long-term recovery of the Lower Willamette River. Please also see Sections 3.1.12 and 3.1.22 of this responsiveness summary.

### **3.6.2 Select a Remedy That Meets Threshold Criteria**

##### **Comment**

The Tribe cannot support EPA's Plan because, even by EPA's own measure, the preferred alternative fails to meet the two threshold criteria of overall protection of human health and the environment, and compliance with ARARs. To address uncertainties in natural recovery, EPA applied an "interim target" approach to evaluate whether efforts will be effective to meet cleanup goals. The Tribe does not believe that EPA has adequately justified the selection of interim targets. Even if the interim targets were justified and appropriate, EPA's preferred alternative meets those interim targets for only 2 of the 9 cleanup goals. We do not understand EPA's conclusion that its preferred alternative will be protective of human health and the environment when it does not even meet most of the interim targets.

**EPA Response**

EPA has revised its preferred alternative to Alternative F Modified. Alternative F Modified further reduces the reliance on MNR, and thereby accelerates the pace at which clean up goals may be achieved. Please also see Sections 3.1.12, 3.1.22, 3.1.23, and 3.1.24 of this responsiveness summary.

**3.6.3 Do Not Focus on Short-Term Impacts****Comment**

The Tribe believes that EPA's decision to select Alternative I is based on a value judgment of the relative importance of short-term construction impacts and cost compared to long-term protection of human health and the environment. In evaluating short-term effectiveness, EPA weighed only the construction impacts of each alternative, but not also the impacts at the Site that will continue to occur and accrue until the Preliminary Remediation Goals are achieved. This approach, coupled with a comparison method that is skewed toward selecting a "middle" remedy, undercuts the purposes of CERCLA to permanently and significantly reduce the dangers associated with releases of hazardous substances.

**EPA Response**

Please see Sections 3.1.12 and 3.1.27 of this responsiveness summary.

**3.6.4 Use Conservative Estimates for Recovery and Focus on Removal****Comment**

Due to the complexity of the river's hydrology and the uncertainty about natural recovery, EPA should utilize the most conservative estimates for natural recovery processes and adopt a remedy that will focus on removal of contamination. While capping may be less expensive in the short-term, caps require long-term maintenance and monitoring. Those additional costs and risks of failure should not be discounted in identifying the most effective remedy for long-term protection of human health and the environment. Further, in order to ensure effectiveness of the remedy, EPA must include a robust and specific monitoring and reporting plan that will identify decision points for determining progress and results that will trigger additional actions.

**EPA Response**

Please see Sections 3.1.3, 3.1.4, 3.1.11, and 3.1.12 of this responsiveness summary.

**3.6.5 Eliminate the Need For Fish Consumption Advisories****Comment**

Tribal members rely on fish (both resident and migratory) for our diet at much higher rates than the general population. Tribal fish consumption is already suppressed due factors such as decreased fish populations resulting from habitat modifications and pollution, and loss of access to traditional tribal fishing sites. Therefore, fish consumption advisories are not an acceptable solution to the Tribe. After 7 years of construction, EPA estimates that fish consumption advisories would allow for approximately 50 fish meals every 10 years. This fish consumption rate is significantly lower than the tribal fish consumption rate of 1,380 resident fish meals per 10 years used in the Baseline Human Health Risk Assessment. EPA must do more to ensure that future generations of Tribal and community members can safely eat all species of fish from the lower Willamette River.

We also believe that EPA must do more to evaluate effects on migratory fish species. Pacific Lamprey is an important species to the Tribe. Currently, Willamette Falls is the only place where the traditional

lamprey harvest continues. Lamprey ammocetes spend years burrowed in sediment and therefore are likely exposed to more Site contamination than other migratory fish.

The Treaty of 1855 guaranteed to the Tribe the right to take fish "at all usual and accustomed places in common with citizens of the Territory." The Tribe would not have signed this treaty without these assurances that our right to fish would be protected into the future. The Nez Perce have held this inherent right to take fish since time immemorial. But a right to fish that is constrained by the inability to consume the harvest because fish are too contaminated to safely eat is like no right to fish at all.

**EPA Response**

Please see Sections 3.1.7, 3.1.12, 3.1.45, and 3.1.46 of this responsiveness summary.

## Section 4

# Oregon Department of Environmental Quality Comments and Responses

## 4.1 Overall Comments

### 4.1.1 Ensure Protection by Issuing a Final Decision and Initiating Cleanup Quickly

#### **Comment**

Contamination levels in some specific areas of the Harbor pose a very real threat to the health of people and families consuming resident fish and shellfish – such as carp, smallmouth bass, catfish, and crayfish – caught in those areas. High levels of contamination in these key areas also pose very significant risks to the ecosystem, including the wildlife, fish, and benthic organisms that rely on this water body. After 16 years of study, we strongly urge EPA to issue the ROD, subject to state concurrence, and begin cleaning up these areas quickly so that the river can be fully returned to its historic role as the cultural, social and economic hub of the City of Portland.

EPA must stick to the current schedule of issuing a ROD in 2016 to avoid a potential cascading series of delays. Delays could result from anticipated changes in EPA administration, growing concerns with the age of the remedial investigation data and – if new data are collected – the need to update the remedial investigation, human health and ecological risk assessments, and feasibility study. The possibility of a major delay at the expense of the health of the river, the community, and the regional economy is simply unacceptable to the state. We acknowledge that some significant project uncertainties remain; however, this is not unusual with large, complex sites. These uncertainties can and should be addressed during remedial design and factored into EPA's long-term strategy for monitoring, reporting, and incorporating adaptive management, as needed, to achieve a protective remedy.

The state encourages EPA to increase efforts in planning for timely implementation of the ROD, with a goal to complete construction within ten years following issuance of the ROD – a timeframe which is in line with the construction duration specified in the proposed plan (USEPA 2016c). Cleanup of the key areas of the Harbor which pose the greatest risks will not happen by itself. Only with a well thought out plan for how to begin work now and encourage responsible parties to participate can we succeed in making the Harbor safe for all of our communities within a reasonable time period.

A successful implementation framework will require the following key elements:

- A mechanism for the Site to be broken into smaller and more manageable work areas (i.e., sediment management areas, SMAs) so that areas posing the highest risks can be addressed sooner.
- Additional data to determine current baseline conditions, more accurately estimate future remedial design and remedial action costs, and support the allocation process. These data can be collected concurrent with remedial design, and should not delay remedy implementation.

- Incentives for responsible parties to enter into remedial design and/or remedial action agreements with EPA to expedite cleanup of SMAs.
- Partnerships with federal, tribal, state and local entities, under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA). Partnerships help ensure that government entities have adequate resources to oversee simultaneous cleanup of multiple work areas, resulting in a cleanup that is faster and more effective than would otherwise occur. When establishing partnerships, carefully delineate EPA and DEQ's roles for overseeing the various aspects of ROD implementation.
- Options for managing the site-wide area outside of the SMAs. This may include encouraging the responsible parties to establish and contribute to a remediation trust.
- Clarity regarding EPA's intended enforcement approach. Creating a framework for increased certainty will increase the likelihood that there will be a critical mass of performing parties.

### **EPA Response**

EPA appreciates DEQ's comprehensive review of the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c) and the state's valuable input. EPA agrees with DEQ that contamination levels in the Site pose a very real threat to the health of people and families consuming resident fish and shellfish and also pose very significant risks to the ecosystem, including the wildlife, fish, and benthic organisms that rely on this water body. EPA also shares the goal of timely construction of the final remedy to achieve the final cleanup goals within a reasonable timeframe. As DEQ indicates, significant remedial design sampling will be required to update existing information to design the cleanup. Early in that process, EPA will collaborate with the various federal, tribal, and state partners. During this planning process, EPA will coordinate remedial actions at the Site with all the stakeholders and support agencies consistent with the MOU to expedite efficient cleanup in river, upriver, and in upland areas. MOU partners will be coordinated with per the MOU framework.

As DEQ is aware and has concurred with, EPA has selected Alternative F Modified as the selected remedy. The construction timeframe for the remedy is 13 years, so it is unlikely that construction will be completed ten years from issuance of the ROD. However, EPA expects that the cleanup work will be conducted by the PRPs under CERCLA agreements with the most expeditious timeframe possible so as to better protect human health and the environment in a timely fashion. EPA will encourage the PRPs and contractors to hire locally but cannot require parties to do so. However, EPA's contractors have federal contracting goals related to the use of minority, women, veteran, and small business subcontractors and strive to use these firms whenever possible. Additionally, at large Superfund sites like Portland Harbor, EPA is often able to provide free training through the SuperJTI to train and help place local residents in cleanup-related jobs. If funding becomes available and the community expresses a desire for such training, EPA could work to make the SuperJTI training available. For additional detail or information go to <https://www.epa.gov/superfund/learn-about-superfund-job-training-initiative#tab-5>.

Specific comments regarding potential post-ROD enforcement or negotiation issues are not related to the selection of a remedy and will not be addressed in this responsiveness summary.

### 4.1.2 Address Environmental Justice through Early Action

#### Comment

Despite existing fish advisories, people – particularly low income, people with limited English proficiency, houseless, and other communities with environmental justice concerns – continue to rely on fish from Portland Harbor as a primary food source. These communities are most at risk for adverse health effects. Avoiding further delay in cleaning up the most contaminated areas of the Harbor and moving forward with implementation now is a matter of environmental justice.

The highest concentrations of the key risk drivers –PCBs, PAHs, dioxins/furans and organochlorine pesticides (DDx) – are present in up to 13 “hot spots” (i.e. SMAs) within Portland Harbor. These contaminants pose the greatest risk to people who eat resident fish and shellfish – such as carp, smallmouth bass, catfish, and crayfish – caught from these areas. At construction completion, EPA’s proposed Alternative I is estimated to reduce the human health risks from eating fish by as much as 100-times when compared to current levels<sup>1</sup>. Further risk reduction of the lesser contaminated areas will occur over the coming decade(s) as monitored natural recovery takes place, primarily through burial from upriver sediment loads and chemical breakdown.

Acknowledging that cleanup of the “hot spots” will not eliminate all health risks and that many decades are likely needed for monitored natural recovery to be fully effective over the remainder of the Site, a plan is needed to protect affected communities now.

A comprehensive update of the existing fish advisories must be implemented as soon as possible following issuance of the ROD, enhanced as new information becomes available, and must remain in place until remedial action objectives are achieved. In addition, the remedy must include active and effective community outreach and education, along with continued monitoring and reporting to the public and affected communities.

An effective early action and community outreach plan should include:

- Prioritizing the timing of remedial actions, so that high use fishing areas, publicly accessible shoreline, and high value natural resource areas are cleaned up as early as possible.
- Providing increased funding and resources for outreach programs, particularly for community-based organizations with connections and expertise needed to conduct culturally-responsive education.
- Providing increased funding and resources for monitoring and regular reporting to both the general public and to specifically targeted communities, including tribes, known to rely on the Harbor as a food source.
- Clarifying the roles of EPA and Oregon Health Authority in developing and implementing fish advisories.
- Establishing clear timeframes for implementing and monitoring fish advisories, and correcting inconsistencies within the feasibility study and proposed plan.

**EPA Response**

EPA agrees that all areas that provide recreation, fishing or other public uses, including high-use areas such as beaches and fishing areas at Cathedral Park, Willamette Cove, and Swan Island Lagoon, should be given priority in the timing of the cleanup to limit direct contact exposure quickly as possible. During the planning and execution of the remedial design, EPA will consider site-specific factors further, including high public use, in sequencing cleanup.

EPA recognizes that fish consumption advisories are more effective with community support. EPA has conducted extensive outreach efforts, including coordinating with the Oregon Health Authority, DEQ, and the City of Portland to inform particularly vulnerable communities of risks associated with contamination in the river and to discuss city/state services that may be available to assist them. Additionally, EPA has engaged with many different groups over the years, including groups that represent or are concerned about communities with environmental justice concerns. Some of the main groups that EPA has engaged with include Communities of Color, Native American Youth Association, Latino Network, Right 2 Dream Too, Right 2 Survive, Willamette Riverkeeper, the Slavic Immigrant Association, Ecumenical Ministries Oregon, the Coalition of Black Men, the Oregon Environmental Justice Task Force, Oregon Tradeswomen, League of Women Voters, Verde, Portland Harbor Community Coalition, Sierra Club Portland, Occupy St. Johns, Audubon Society, Asian Pacific American Network of Oregon, Vietnamese Community of Oregon, Portland neighborhood associations and schools. EPA will continue to work with these groups and other interested parties to make sure that future outreach efforts reach historically underrepresented communities.

During remedial design, consistent with EPA Superfund guidance on ICs, EPA will look to the PRPs to develop an ICs implementation and assurance plan that lays out the approach for the development and implementation of ICs, including fish consumption advisories and timeframes. The primary goal of the plan is to establish and document the activities necessary to implement and ensure the long-term stewardship of ICs, and specify the persons and/or organizations that will be responsible for conducting these activities such that the roles of EPA, Oregon Health Authority, and others are well understood. In development of the plan, coordination with river users, property owners, communities and other stakeholder groups will be sought with a goal to minimize the negative long-term impacts of ICs as part of the remedial action.

EPA will continue outreach and education efforts tailored to the affected communities to ensure that fish consumption advisories are effective and appropriate, advisory signs are designed, installed, and maintained effectively and at the appropriate locations, in coordination with Oregon Health Authority, Multnomah County Department of Health, and the City of Portland. In addition, based on long-term monitoring as determined in the five-year review process required under CERCLA, fish consumption advisories will be re-evaluated to ensure they are fully protective but not overly restrictive and on target to meet long-term goals of the remedial action. This may include special consideration of high use areas such as beaches and fishing areas at Cathedral Park, Willamette Cove, and Swan Island Lagoon. Additional information on ICs is provided in Section 2.28 of this responsiveness summary.

**4.1.3 Evaluate MNR Effectiveness in Detail after the ROD****Comment**

The proposed plan identifies monitored natural recovery as the primary remedy for areas of the Site that are outside of the active sediment management areas (approximately 85 percent of the Site). Monitored natural recovery is relied upon to reduce site risks and achieve project remedial action objectives over time, including a period of time after construction completion. The effectiveness of

monitored natural recovery is highly dependent on clean sediments suspended in the water column that enter the Site from upriver. Water column data collected during the remedial investigation by LWG and others indicate that monitored natural recovery is unlikely to achieve risk-based protective levels for PCBs without additional measures being taken upriver of Portland Harbor.

DEQ oversaw sediment cleanup actions in the “Downtown Reach” of the Willamette river – the four-mile reach immediately upriver of Portland Harbor – beginning with the Portland General Electric Station L site in the late 1980s. Additional cleanup actions included Ross Island Lagoon, Zidell, and Portland General Electric River Mile 11.5 East. DEQ expects that remedial actions at two other sediment sites will be completed in summer 2017 or 2018: the Former Portland Gas Manufacturing Plant at the north end of Tom McCall Waterfront Park conducted by Northwest Natural, and a PCB contaminated site on the east end of the Hawthorne Bridge conducted by Portland General Electric. Comprehensive sediment investigations by the City of Portland, DEQ, and others between 2009 and 2010 and fish tissue samples collected by LWG in 2012 have revealed potential data gaps and indicate that more investigations are necessary to confirm that the Downtown Reach will not limit the effectiveness of monitored natural recovery in Portland Harbor. DEQ will increase its efforts working with potentially responsible parties and stakeholders to expeditiously complete this important work.

DEQ is also assessing the health of the Willamette River watershed and the attainment of state ambient water quality standards, which are some of the most stringent in the country. This includes comprehensive sampling of co-located sediment, water, and fish tissue for PCBs and other contaminants throughout the Willamette River watershed and parts of the Columbia River.

The elements of a comprehensive monitoring plan should include:

- A description of how EPA will assess the effectiveness of monitored natural recovery following issuance of the ROD in consideration of improvements in Downtown Reach sediment quality, better information on watershed health, post-ROD baseline data, and long-term performance monitoring.
- Collaboration with DEQ’s cleanup and water quality programs, EPA’s CERCLA and water quality programs, tribal and local governments and other stakeholders to develop an approach for assessing performance of the in-river remedy, loading from upriver sources, and the effectiveness of source control measures.
- A process for evaluating and implementing corrective actions, as needed, for managing downstream transport of site contaminants through engineering and turbidity controls, construction monitoring, and site-wide monitoring.

### **EPA Response**

EPA will be monitoring and commenting on DEQ activities both upriver and upland to ensure that this work is compatible with the cleanup work being undertaken as part of this ROD, and to determine if further action upland or upriver is necessary. EPA agrees that a comprehensive monitoring plan will be required and will coordinate with DEQ, tribal and local governments, and other stakeholders on its development after the ROD and during the remedial design. Section 14.2.7 of the ROD describes the significant baseline sampling that will be undertaken to update existing information and to design the cleanup. Baseline sampling will include areas upstream and downstream of the areas that are the subject of this ROD.

During active remediation activities (such as dredging, capping, placement of clean sediment for ENR) there will be monitoring in the construction area as appropriate. The cleanup activities performed in the river will need to comply with water quality standards near where the activity is taking place. Air samples may be collected to make sure contaminants do not exceed worker health-based concentration levels in air as well as ensuring unacceptable levels are not leaving the work area. If contaminant levels exceed water or air quality standards, the work will be modified, and additional controls will be taken as needed. In addition, collection of sediment, surface water, pore water, and fish tissue samples will be collected during the construction period.

Following construction, there will be long-term monitoring until and after the cleanup goals are achieved (ROD Section 14.2.7). The long-term monitoring program will at least include sediment and tools to monitor sediment movement, such as sediment traps, river banks, surface water, pore water, and fish tissue samples from upstream, within, and downstream of the Site. Passive samplers may also be used to supplement fish tissue data as a surrogate for fish tissue, as well as a tool to achieve lower detection limits in monitoring the water column. Data on contaminant levels will be used for multiple purposes, such as to determine if natural recovery is taking place as expected or if any additional actions are required to achieve the cleanup goals on the planned timeline; track if fish tissue concentrations are decreasing; and monitor if the caps are effectively containing the contaminated sediment and/or groundwater. Data on contaminant levels in fish tissue will also help inform when and how the fish consumption advisory or other restrictions could be relaxed.

Long-term monitoring will include regular inspections of the sediment caps to make sure they are in the proper place, have the required thickness and type of capping material, are achieving RAOs such as pore water standards, and are functioning as intended. Cap inspections may also be required after natural events such as earthquakes or floods, and manmade events such as boat collisions or violations of land use restrictions. Monitoring and maintenance of the caps would be required in perpetuity. Refer also to Sections 2.17.3 and 2.27.1 of this responsiveness summary.

#### **4.1.4 Aggressively Clean Areas Posing Risk to the Benthic Community and Lamprey**

##### **Comment**

As referenced in the proposed plan, the EPA-approved BERA (Windward 2013) found that unacceptable risks to benthic invertebrates are located in approximately 4-8 percent of the Harbor; however, the feasibility study (Figure 4.1-1) incorrectly identifies approximately 60 percent (1,289 acres) of the Harbor as having unacceptable benthic risk. The area presented in the feasibility study was defined using the lowest of contaminant-specific toxicity reference values (TRVs) from the risk assessment as PRGs in sediment. This area is much larger than the benthic risk area predicted by site-specific models used in the BERA (the Floating Percentile Model and Logistic Regression Model) and does not include some areas which were predicted in the BERA to have moderate to high toxicity to benthic organisms. The state recommends a revised approach which would remediate all sediment areas of unacceptable benthic risk at construction completion, thereby protecting lamprey ammocetes that occupy the same benthic feeding guild, exposure route, and chemical sensitivity as sediment invertebrates.

The approach for addressing benthic risk should be updated by:

- Using the PRGs derived from the Logistic Regression Model with a Pmax of > 0.5 (indicating moderate and high toxicity) to define the benthic risk area. The state recommends using this

model because it is nationally peer reviewed, incorporates models and toxicity correlations for individual contaminants, and represents comprehensive model predictions to both test species (Hyalella and Chironomus) and endpoints (survival and biomass).

- Incorporating the benthic risk area from the Logistic Regression Model into the Alternative I active remediation area. This is estimated to add approximately 43 acres to the current Alternative I active remediation footprint and enhanced natural recovery area.
- Using a bioassay “test out” option during remedial design to confirm benthic risk and the need for active remediation in these additional areas.
- Allowing for an engineering evaluation of the effectiveness of enhanced natural recovery to address benthic risk areas outside of the current Alternative I footprint.

### **EPA Response**

The evaluation of benthic risk in the BERA (Windward 2013) for the Portland Harbor Site considered multiple lines of evidence including sediment toxicity testing, the floating percentile and logistic regression predictive models, generic sediment quality guidelines, tissue residue assessment and comparison of surface water and transition zone water to water based toxicity reference values. As a result, reliance on a single model such as the Logistic Regression Model to assess risks to the benthic community is not consistent with the procedures used to assess benthic risk in the BERA.

The 4 to 8 percent number is based on the comprehensive benthic risk assessment. The feasibility study report (USEPA 2016b) used a different approach (comparison to RAO 5 PRGs). A total of 1,290 acres of benthic risk areas were identified using this approach, which is approximately 60 percent of the Site. Refer *Benthic Risk Theme Response* for additional details.

The sediment PRGs developed for RAO 5 (reduce risk to benthic organisms from ingestion of and direct contact with COCs in sediment to acceptable exposure levels) considered the tissue residue line of evidence, and the two site-specific predictive models of toxicity to benthic species. The lowest of these values for a given contaminant was selected as the RAO 5 PRG. COCs for which a site-specific value could not be developed (Lindane and zinc) relied on sediment quality guidelines (Probable Effect Concentrations taken from McDonald et al [2000]) and are used as the PRG. Water based exposures are addressed through RAOs 7 and 8. Thus, the PRGs presented in the final feasibility study report consider all lines of evidence (including toxicity through the use of the predictive models) considered in the evaluation of benthic invertebrate risk in the BERA rather than a single predictive model.

As presented in Figure 2.2-2 of the final feasibility study report, areas of benthic risk identified in the feasibility study report represent 1,290 acres of the Site. However, as further noted in the feasibility study report, interim targets for risks and hazard indices were established to evaluate the potential for achievement of PRGs in a reasonable time frame. For RAO 5, the interim target is based on multiplying the RAO 5 PRG by an order of magnitude to account for further reductions due to MNR. In addition, the post-construction interim target for RAO 5 was established at a 50 percent reduction in the area posing unacceptable benthic risk because risks to the benthic community are based on a population level rather than individual level effect and is considered a target to which the benthic population as a whole can be stressed and still recover. As shown in Table 22 of the ROD, EPA’s selected remedy, Alternative F Modified, addresses 72 percent of the area with unacceptable benthic risks (the area that exceeds 10 times the benthic risk value).

During remedial design, additional data to be collected for selection and design of the remedial technology to be implemented in specific locations may include toxicity testing, as applicable to refine delineation of benthic risk areas, where benthic risk only is the driver for achieving cleanup levels in a particular area. Also, ENR will be assessed during site-specific design work for its ability to accelerate risk reduction (expected thru MNR albeit on a longer time scale) on a case by case basis.

#### 4.1.5 Accommodate Current and Future Uses of the Harbor

##### Comment

Portland Harbor is an important reach of the Willamette River. This waterway simultaneously serves as a center for the region's economy, a cultural resource for tribes, a social and recreational resource for the City of Portland, and an important aquatic and riparian habitat for fish and wildlife – all of this in the midst of Oregon's most densely populated area.

The current and future uses of the Harbor must be preserved by:

- Ensuring that the remedy is compatible with, and does not irrevocably limit the current and future uses of, adjacent upland sites. This congruity is particularly important at adjacent upland site with a designated marine-dependent use under the City of Portland's recently-updated Comprehensive Land Use Plan.
- Retaining the two existing boat ramps within the Harbor at Swan Island Lagoon and Cathedral Park, and ensuring that at least one of these ramps is made available for public use at all times during construction. The remedy must not limit the current or future use of these popular fishing access areas, nor include restrictions that impact ramp maintenance or replacement.
- Minimizing the use of regulated navigation areas or water use restrictions in cap areas that limit restrictions on boat traffic, anchoring, or spudding where possible.

##### EPA Response

EPA appreciates the importance of the river for industrial, commercial, and recreational uses and the economic vitality of the region. Of the 2,167-acre Site, active cleanup would take place in approximately 394 acres, or only about 18 percent of the Site. Cleanup activities will likely take place within that small portion of the Site at different times throughout the construction period, as determined during remedial design. As such, portions of the river will be inaccessible for some portion of the construction period, but much of the river and harbor would remain open. It is EPA's intention to avoid or minimize to the extent feasible, closing even on a temporary basis public access areas such as public boat ramps.

EPA has conducted extensive community outreach during all phases of the project and is committed to maintaining a transparent, proactive community interaction process during each cleanup phase, with informal comment opportunities on all key elements of the design and implementation. EPA is committed to working with the community to minimize any short-term impacts, including any temporary disruptions to public amenities.

EPA recognizes that Regulated Navigation Areas (RNAs) have impacts on the community as well by restricting public uses. In addition, RNAs may impact some property owners' ability to use and maintain their facilities and to construct or develop new features on their property in certain areas, or add expense to do so properly (as approved by EPA). However, limitations on some uses of the river may be needed to implement a cost-effective and protective remedy that addresses releases of

hazardous substances. The feasibility study report (USEPA 2016b) evaluated the reliability and implementability of Waterway Use Restrictions or RNAs. Such designated restricted areas may be necessary to ensure the integrity of caps are maintained by limiting activities that could affect the ability of the cap to contain contaminated sediment or groundwater from being released to the environment. This could include prohibiting anchoring of vessels or the use of spuds to stabilize vessels in areas containing caps. Notifications such as signs and buoys may be used to warn vessels from the area.

RNAs have been successfully used in the past to protect remedial actions at the Site. RNAs were required to protect the McCormick and Baxter cap and the Gasco interim action cap from vessel activities. Periodic inspections of RNA notifications will be needed to ensure they are functional and effective. During remedial design, decisions as to where dredging and capping will occur will be made and necessary ICs to protect the cleanup will also be determined and implemented. Where possible, caps should be designed to minimize the need for RNAs but will have to be fully effective in containing contaminated sediment or groundwater and consistent with anticipated land uses

The enforcement of RNA-related ICs with respect to the governmental entity that will provide enforcement authority will be determined during the development of remedial design and identification of responsibilities in an ICs implementation and assurance plan and operation and maintenance plan to be developed jointly between federal agencies (such as EPA, USCG, etc.) the appropriate agencies from the State of Oregon.

The ICs implementation and assurance plan approach for the RNAs IC may include, but not be limited to, the following:

- Form an inter-agency team made up of representatives from EPA, DEQ, tribes, Oregon Department of State Lands, Coast Guard, Oregon Marine Board, Oregon Department of Transportation, U.S. Army Corps of Engineers, City of Portland, Port of Portland, and others to identify key concerns about the development and implementation of RNAs at the Site, including ongoing and future maintenance dredging, and emergency access plans
- Work with land-owners along the Site to identify and map nearshore and river bank structures, facilities, and associated activities that may affect the siting and/or effectiveness of RNAs
- Map the river uses on a facility and site-wide scale for the purpose of delineating RNAs and evaluating their overall impact with reasonably anticipated land uses
- Where necessary to protect caps or other remedial features, establish RNAs limiting waterway and land use activities such as boat anchoring and keel dragging, structure and utility maintenance and repair, and future maintenance dredging
- Conduct outreach and education to recreational boating communities and other river users regarding RNAs to ensure they are effective and appropriate, RNA notice signs are designed, installed, and maintained effectively and at the appropriate locations, in coordination with the inter-agency team
- Monitor the effectiveness of RNAs and other ICs such as fish consumption advisories as part of long-term monitoring for the Five-Year Review process

During remedial design, EPA and the PRPs will consider site-specific factors, including river use restrictions related to RNAs, and will coordinate with USACE and other agencies through the IC planning process for selection of the preferred remedial technology that best meets required objectives, including protection of human health and the environment while factoring in implementability concerns.

#### 4.1.6 Consider Potential Impacts of Transportation Modes

##### Comment

Alternative I includes removal of nearly 2 million cubic yards of soil and sediment from the river. This material will need to be transported and disposed of in a manner such that it no longer poses a risk to human health and the environment. The proposed plan retains truck, rail and barge shipment of dredge materials as potential modes of transportation. The state is concerned that transporting materials and equipment to or from the site (or transloading facility) by truck would increase road congestion and air emissions, which have real economic, community livability, and environmental consequences. A remedy that relies on trucks would also have a greater impact on roadway infrastructure, requiring greater maintenance and repair.

The impacts from transporting dredge material must be considered by:

- Identifying a preference in the ROD for transporting dredge spoils by rail and barge.
- Acknowledging that the transportation needs and impacts associated with each transportation mode will be evaluated and considered during remedial design to ensure that transportation modes are thoughtfully selected, balanced, and minimize impacts to surrounding communities, transportation safety, and infrastructure.

##### EPA Response

The ROD has a preference for lower impact transportation methods for the transport of dredged sediment that will minimize the impact to surrounding communities (such as rail or barge). Dredged material would be loaded directly into barges and transported for dewatering, treatment, or further transport for disposal. River bank materials excavated from above the water line were assumed to be loaded directly into containers to be transported by rail or barges for transport.

EPA concurs with DEQ that transportation modes will need to be carefully considered during design and implementation of the selected remedy. Because all of the various external factors that could affect mode of transport (such as location of transload facilities, selection of disposal facilities, volumes of wastes and materials generated for transport over the length of construction, etc.) cannot be fully known at this time, the modes of transport in the feasibility study report (USEPA 2016b) to be used will not be prescribed. However, EPA did assume barging as the representative mode of transport because it reduces environmental impacts and enhances community and worker safety over other modes of transport. During remedial design, EPA will work with the entities implementing the remedy to carefully evaluate and select the most appropriate modes of transport to account for factors such as reducing environmental impacts and short-term impacts. A green remediation plan will be prepared for each action which will discuss how impacts will be mitigated to the extent possible and as part of this analysis rail and barge transport of wastes will be discussed, and used wherever possible to limit greenhouse gas emissions and lessen neighborhood impacts for air toxics such as sulfur oxides, consistent with EPA national and regional guidance. Where trucking cannot be avoided, the plan will discuss optimum haul routes to minimize diesel exhaust exposure to sensitive subpopulations (known to cause childhood asthma), such as residential streets near schools.

### 4.1.7 Allow Design Flexibility to Account for Uncertainty

#### Comment

Portland Harbor is considered a “Mega Site” due to its extraordinary size and level of complexity. Although extensive site-wide data have been collected over the years, there are still a number of uncertainties in the physical, chemical, and regulatory elements of the Site. For a sediment site of this magnitude, this is not unusual; however, EPA must support a design process that incorporates flexibility as a means for addressing these complexities and uncertainties while assuring compliance with the ROD.

No one-size-fits all approach can accurately predict and account for the unique characteristics of individual areas in the river. Professional judgment and experience must play a strong role to ensure that the remedy constructed is protective of the human health and the environment at individual SMAs in the river.

Flexibility in remedial design can be achieved by:

- Acknowledging that a standardized decision-making approach was applied for ease in developing site-wide remedial alternatives, but modifications to this approach will be needed to refine the selection and extent of remedial technologies on an SMA-specific scale. This may include consolidating or smoothing the pixilated areas of dredging and capping to improve constructability.
- Acknowledging that the conceptual site model will likely need to be updated during remedial design for specific SMAs. For example, surface water and tissue data at the Willamette Cove site suggests that there may be an active in-river source(s) not yet identified which may require an alternative remedial technology.
- Describing how subsurface contamination will be considered during remedial design, if at all, in defining the boundaries of active remediation areas. It is the state’s understanding that SMAs identified in the proposed plan are mapped by comparing RALs to surface sediment chemistry and not subsurface chemistry.
- Giving equal preference to dredging and capping in the intermediate river region where there is no NAPL. The ROD should not require capping of these areas if Performing Parties determine during remedial design that dredging is more cost effective or otherwise preferable in order to avoid requirements for long-term cap monitoring and maintenance and reduce compensation to the Department of State Lands. Similarly, the ROD should not require dredging if a more detailed assessment during remedial design discovers substantial amounts of buried debris, geotechnical hazards or other conditions that would increase the risk of contaminant resuspension and downstream transport, risk to construction workers or otherwise render dredging to be infeasible.
- Describing criteria for selecting thin-layer sand capping, called ENR, at Swan Island Lagoon. Allow for refinement of the ENR footprint, if appropriate, after a more in-depth assessment of sediment deposition rates. For example, it’s unclear why monitored natural recovery would not be effective in the downriver portion or the lagoon.
- Allowing flexibility to accommodate future in-river infrastructure projects. For example, a cap in the vicinity of a bridge will impact ODOT’s ability to perform maintenance and construction

work around bridge support structures in the river if a cap is not carefully located. For seismic upgrades on the St. John's Bridge and the Fremont Bridge, the bridge piers will increase in size by as much as 50 percent and the in-river work would require a setback of approximately 20 feet around the piers. If a cap is placed in the vicinity of a bridge pier before seismic upgrades occur, the cap could be damaged from construction equipment anchoring or disturbing the river floor.

### **EPA Response**

EPA acknowledges that new data will be collected during remedial design. These data will be used to support future decisions regarding remedial action footprints, technology assignments, use restrictions or other ICs, treatment and disposal of dredged material, mitigation requirements, among others. This new data will be used to update the CSM. If new information indicates that a different technology, beyond dredging and capping is necessary, what additional analysis to determine the alternative will be determined at that time.

Subsurface contamination data will be collected, refined and evaluated in defining the boundaries of active remediation areas during remedial design phase of the project. The ROD includes a flexible decision tree along with general design requirements to guide the assignment of capping and dredging technologies, based on specific characteristics within SMAs. The decision tree will be used during remedial design to define what actions should be taken under different environmental conditions and locations based on the most recent design data. Once the data and river factors are evaluated within the context of the decision tree, a final design for construction can be completed. This design will then dictate the remedial construction. The decision tree is intended to provide clear direction on what actions should be taken under the different conditions and locations.

The feasibility study report (USEPA 2016b) identified areas for dredging or excavation or capping based on site-specific factors that may limit the effectiveness of containment, in-situ treatment, enhanced natural recovery ENR or MNR. Within the navigation channel or future maintenance dredge areas, removal was required to prevent restrictions on navigation. In the intermediate areas, a multi-criteria decision matrix was developed as a method to guide the assignment of capping and dredging technologies, based on site-specific characteristics within sediment management areas. In shallow areas, a mix of shallow removal followed by capping or placement of backfill was utilized to maintain current water depth and thus limit the loss of shallow water aquatic habitat.

The selected remedy was chosen in order to provide a balance between minimizing the time required for remediation and implementing a suitably protective cleanup to minimize the risk to public health and the environment in the future, in an area where ENR is very likely to be highly effective. EPA's analysis of alternatives shows that a larger, removal-based remedy in the Swan Island area would not considerably improve public health and environmental protection, would take a longer, cost substantially more, and have greater short-term impacts to the benthic community and aquatic organisms and to the community surrounding the area because of dredging activity (see Section 2.31.2 of the responsiveness summary and 10.1.17 of the ROD. After the remedy has been implemented, EPA will use sampling and monitoring results to guide and refine the cleanup action selected to provide additional assurance that the process is reducing contaminant concentrations and bioavailability as expected.

As mentioned above, the selected remedy was chosen to provide a balanced approach in achieving remedial cleanup levels. The ROD includes a flexible decision tree which will dictate the design and

remedial construction and is intended to provide a clear direction on what action should be taken under different conditions and locations.

EPA's remedy decision primarily selects final cleanup levels for the COCs at the Site and establishes remedial action levels for focused COCs that triggers more active cleanup technologies than MNR. EPA agrees that maintaining flexibility in construction methods through the remedial design phase is an important consideration. Additionally, EPA agrees active cleanup technology assignments will be evaluated during remedial design based on new data and area-specific conditions and land uses and other requirements specified in the ROD. As pointed out by the state, status of source control efforts will be evaluated during design, to ensure that upland and in water sources are accounted for by the remedial approach.

As mentioned above, the decision tree will be used during remedial design to define what actions should be taken in different areas of the Site based on the most recent design data. Once the data and river factors are evaluated within the context of the decision tree, a final design for construction can be completed. Based on empirical data, if MNR is shown to be sufficiently effective, it may be selected over ENR in certain portions of Swan Island Lagoon. Dredging in areas where capping is prescribed will be allowed on a site-specific basis, e.g. where dredging is more conducive to future site uses. Likewise, future plans for infrastructure such as oil pipelines, electricity transmission cables, and upgrades to bridge structures will be accounted for during both the design and approach taken in the sequencing of a cleanup, e.g. accelerating a transmission line replacement that is planned before placing a protective cap in an area.

#### 4.1.8 Realize Cleanup Costs are Uncertain and Likely Underestimated

##### Comment

The state is concerned that EPA's cost estimate for Alternative I may underestimate the actual total project cost, and that the proposed plan does not adequately describe key uncertainties with the estimate. The state recognizes the difficulties in developing an accurate cost estimate for a site as complex as Portland Harbor, but requests that the ROD provide additional clarification about cost assumptions, uncertainties and sensitivities.

Project uncertainties in the estimated cleanup costs should be accounted for by:

- Acknowledging that the actual cost of Alternative I will likely fall outside the desired range of -30 percent to +50 percent the estimated cost that is specified in EPA guidance documents.
- Identifying cost assumptions with the greatest amount of uncertainty, which have potential to most significantly influence the total project cost. The state anticipates that handling, transporting, treating, and disposing Subtitle C and Subtitle D dredge material will have the greatest potential to significantly increase the cost of the remedy due to uncertainties in the disposal volumes and treatment requirements for this material. Further complicating this effort is the uncertainty of a local disposal option for Subtitle D dredge material, particularly in light of the widespread opposition to the proposed confined disposal facility (CDF) at Terminal 4. If an acceptable facility were developed that could handle most or all of the Subtitle D wastes without the need for transloading to rail or truck, significant cost savings would be realized, not to mention increased implementability, reduced implementation risk and reduced carbon footprint/ greenhouse gas emissions. An example of a potential facility not contemplated in the feasibility study is the former Boise White Paper wastewater lagoon recently proposed by the

City of St Helens as a regional, state-permitted, disposal site for dredge spoils and other non-hazardous wastes. Other key costs with significant uncertainty are open water dredging, project management, remedial design, mobilization/ demobilization and contingency (scope and bid).

- Including a table comparing the non-discounted costs against a range of discount rates as done for the Lower Duwamish Waterway Superfund Site. Discount rates are used as a tool to predict the money needed today to fund the project into the future, largely based on predicted interest rates for the project duration. The state suggests comparing non-discounted costs to a 7 percent discount rate, per EPA's guidance, and the 2016 30-year real discount rate of 1.5 percent, to better reflect current economic conditions.

### **EPA Response**

EPA does not agree that the intended costs will likely fall out of the range of expected cost accuracy as intended in EPA guidance. EPA's cost estimates were produced consistent with EPA guidance by using a proper cost methodology as described in guidance, using appropriate cost sources, and reasonable assumptions and related quantities. The expected accuracy stated in this guidance for feasibility study cost estimates is +50 percent to -30 percent of actual cost, which means that a remedial alternative's cost at the time of construction could be as much as 50 percent higher or 30 percent lower than as presented in the proposed plan (USEPA 2016c). These estimates are not intended to be highly detailed because the scope of the alternatives in a feasibility study is much lower than later during design and construction of a remedy when more data are available and there is a better understanding of the construction timelines and funding. This is particularly true of projects such as the Portland Harbor cleanup where the scope of the cleanup is large (over many river miles), so the sequencing of construction work will likely be complex. The cost estimates are developed to reflect the understanding of the alternatives as described in the feasibility study report (USEPA 2016b) given the understandable uncertainties that exist and will continue to exist even after a decision on a remedy approach is made, prior to design and construction. Cost estimates prepared later in the Superfund process, when more information is available, will be developed to address project budgeting with a corresponding higher accuracy.

EPA has documented the methodology and assumptions used in developing feasibility study cost estimates in Attachment A of Appendix G of the 2016 feasibility study report. Cost estimates were developed according to "*A Guide to Developing and Documenting Cost Estimates during the Feasibility Study*" (USEPA 2000) and include the level of detail and backup suggested by the guidance to meet the accuracy requirements for feasibility study cost estimates (-30 percent to +50 percent of actual cost). While there is some uncertainty about the cost impacts from waste treatment and disposal assumptions, EPA's assumptions on these issues were based on actual work that has previously occurred at the Site during early actions.

As part of the effort to address concerns about cost uncertainties, EPA and DEQ collectively performed a "deep dive" into cost estimate drivers and related assumptions starting in early 2016. That analysis showed that waste transport, treatment, and disposal costs were significant drivers for all alternatives with respect to overall costs. As a result of that identification, EPA reevaluated transport, treatment, and disposal assumptions including using information from early action work within Portland Harbor and contact with the representative transport and disposal facilities. This information was used to refine costs as much as can be done at a conceptual phase of the project. EPA's position is that sufficient due diligence has been done with respect to addressing concerns about significant cost drivers for the feasibility study. It should also be noted many of these same drivers were addressed in

the sensitivity analysis presented in Appendix N of the feasibility study report. This is consistent with the recommendation in the third paragraph on Pages 4 and 5 of the guidance (USEPA 2000) and with DEQ's request to understand cost sensitivity.

EPA recognizes that the intended purpose and use of cost estimates during a feasibility study for remedial alternatives may be misunderstood by those not familiar with the Superfund process, leading to the incorrect perception that feasibility study cost estimates are "inaccurate" or not the "true" costs or may fall out of the intended range of accuracy. The stated purpose for feasibility study cost estimates is to compare remedial alternatives during the remedy selection process, not for establishing construction project budgets nor for negotiating Superfund settlements with potentially responsible parties to pay for cleanups.

EPA recognizes that potential significant cost savings that could be realized if a proposed disposal facility in close proximity to the Site and adjacent to the river to minimize transload requirements is available for disposal of dredged contaminated sediments and excavated river bank soils.

EPA will consider the potential use of the proposed facility for disposal of contaminated sediments and soils (excluding those sediments characterized as containing Resource Conservation and Recovery Act /state hazardous waste or Toxic Substances Control Act waste). EPA's consideration will be contingent upon the proposed facility's ability to conclude the Subtitle D permitting process, meet EPA's requirements under the "Off-Site Rule", and be available for disposal during the implementation of remedial action at the Site. Since it is expected that responsible parties will be implementing cleanups, if a facility otherwise complies with the Off-Site Rule and is appropriate for the waste to be disposed, EPA cannot mandate or require the use of a particular disposal facility if other approved facilities are available and selected by the responsible parties.

It should be noted that while EPA used a 7 percent real discount rate for presentation of the alternative costs, a sensitivity analysis was performed for varying discount rates and presented in Appendix N of the feasibility study report. This is consistent with the recommendation in the third paragraph on Pages 4 and 5 of the guidance (USEPA 2000) and with DEQ's request to look at additional discount factors. See also Section 2.22 of this responsiveness summary.

#### 4.1.9 Focus Cleanup Levels on the Sediment Remedy

##### Comment

It is critically important that EPA provide clarity regarding when the CERCLA cleanup is complete. Portland Harbor was listed under CERCLA as a sediment site, and the remedial alternatives evaluated in the feasibility study are based on cleanup of contaminated sediment. In the proposed plan, EPA proposed PRGs for surface water, groundwater (porewater) and fish tissue. These non-sediment PRGs have potential to cause significant confusion and uncertainty. The state considers the primary goal of the remedy to reduce sediment contamination to risk-based or background levels. This will, in turn, result in reducing contaminants in fish/shellfish tissue, groundwater (porewater), and surface water. Further reductions in all media will be achieved through source control and watershed actions. Therefore, cleanup of contaminated sediments will contribute to meeting the remedial action objectives for other site media, but will not independently meet them.

The state is concerned about using PRGs for fish tissue, surface water, or groundwater as formal cleanup levels in ROD, particularly where there is not a thorough understanding of the technical practicability of achieving and measuring these criteria. For example, many of the surface water,

groundwater (porewater), and tissue PRGs (e.g. PCBs, DDx) are set below background levels. Also, the PRG for surface water and porewater PCBs, for example, is well below analytical detection limits. In addition, the contribution to porewater from contaminated sediments versus contaminated groundwater plumes is indistinguishable for some contaminants; this is not accounted for in the decision trees for the technology assignments.

The cleanup goals should be clarified by:

- Establishing formal cleanup levels based on sediment PRGs only.
- Retaining the surface water, groundwater, and fish/shellfish tissue criteria as measures of progress to evaluate the effectiveness of the sediment remedy in reducing risks associated with these media, but not as formal cleanup levels, similar to what was done on the Lower Duwamish Waterway.

### **EPA Response**

Releases of hazardous substances have occurred to surface water and groundwater, in addition to sediment, that present unacceptable risk to human health and the environment in the in-river portion of the Portland Harbor Site, therefore, it is appropriate to develop cleanup levels for these media. Likewise, fish and shellfish tissue PRGs were derived because tissue concentrations represent a direct exposure point for human and ecological receptors, and because target tissue concentrations are needed to derive sediment PRGs for protection of human health due to fish consumption.

Consistent with CERCLA and the NCP, cleanup levels are to be developed based on chemical-specific ARARs, including MCLs promulgated under the Safe Drinking Water Act and water quality criteria established under the sections 303 or 304 of the Clean Water Act if more stringent than state-promulgated standards and relevant and appropriate under the circumstances of the release. Thus, cleanup levels for surface water and groundwater are based on state water quality criteria, federal 304(a) criteria, and MCLGs/MCLs or regional screening levels when there was no SDWA standard. Upon considering public comments on fish tissue PRGs, EPA has decided to make fish tissue levels target goals instead of enforceable cleanup levels.

EPA disagrees that surface water and groundwater cleanup levels should not be established without a thorough understanding of the technical impracticability to achieve them. Rather, evidence is required first to show it is technical impracticable to attain ARARs before they can be waived. At this time, there is no such evidence to support ARAR waivers.

See Section 2.3 of this responsiveness summary for more detail regarding surface water, groundwater, and fish/shellfish tissue criteria as measures of progress to evaluate the effectiveness of the sediment remedy in reducing risks associated with these media.

### **4.1.10 Revise River-Bank Approach to Be Consistent with Joint Source Control Strategy**

#### **Comment**

In 2005, DEQ and EPA developed a Joint Source Control Strategy, which identifies a framework for conducting source control work consistent with anticipated in-river remedy objectives. This framework includes a process for screening and evaluating river banks to determine whether remedial action may be required. The state understands that the intent of RAO 9 is to reduce migration of contaminants from river bank soil to sediment and surface water, such that levels are

acceptable for human health and the environment. This objective can be adequately addressed under an updated Joint Source Control Strategy framework.

The approach to river bank cleanup should be revised by:

- Referring to the joint source control strategy for using site-specific lines and weights of evidence to determine whether a river bank source control measure is warranted. The joint source control strategy should be updated to use in-river sediment preliminary remediation goals as screening criteria for river bank source control evaluation. However, the PRGs for remedial action objective 9 should not become formal cleanup levels. This change also addresses the DEQ's concern that the RAO 9 PRGs for arsenic, cadmium and mercury are lower than upland background values determined by DEQ5. Neither EPA nor DEQ have conducted a background evaluation to determine upland background concentrations for the organic compounds. It is likely that the PRGs for some of the organic compounds are also below background.
- Making a distinction between river banks referred to EPA that have been identified by DEQ as contaminated and requiring a bank source control measure, versus those that are contaminated with a need for bank action to be evaluated during remedial design.

#### **EPA Response**

EPA is committed to ensuring that upland and upriver contaminant sources to the Willamette River are controlled because source control is critical in achieving the remedial action objectives for the Portland Harbor cleanup. Please also see LSS Dispute Issue 14 and 18 and LWG Dispute Issue 1q responses.

The Joint Source Control Strategy is a living document, and EPA is confident that EPA and DEQ will continue to update the strategy as appropriate post ROD to account for new information, such as incorporating the final cleanup levels in the ROD. EPA will be seeking new data post ROD, and will incorporate new information regarding background values such as those for arsenic, cadmium and mercury. River banks referred to EPA versus not will continue to be evaluated as new data are gathered. River banks that require cleanup where contamination is contiguous between and upland area and area in water to be dredged or capped will be cleaned up together in most cases, to minimize overall impact on the environment, expedite cleanup, and minimize recontamination potential.

#### **4.1.11 Consider the Different Types of Groundwater Plumes in Cleanup**

##### **Comment**

The proposed plan calls for in-situ treatment for residual groundwater plumes potentially discharging contaminants to the river. The state is concerned that the prescriptive technologies identified for groundwater plumes do not adequately consider the various types of plumes present within Portland Harbor.

The cleanup actions for groundwater plumes should be refined by:

- Updating the decision trees for the shallow and intermediate regions to identify two categories of groundwater plumes.
  - Groundwater plumes that are expected to naturally attenuate. If a plume will attenuate in a reasonable amount of time, no additional treatment or engineering

controls would be required such as the addition of activated carbon to the residuals layer or construction of a reactive engineered cap.

- Groundwater plumes that are not expected to naturally attenuate. For plumes that are not expected to attenuate in a reasonable amount of time (e.g., portions of the Gasco, Rhone-Poulenc and Arkema plumes) reactive engineered caps should be the assigned remedial technology within the groundwater plume discharge area.
- Considering the compatibility of the selected remedy with upland source control efforts in areas with groundwater plume discharge, and with the aim of integrating in-river and upland remedies.

### **EPA Response**

Early source control actions conducted under DEQ authority are not final CERCLA actions. EPA will be evaluating the effectiveness of any source control actions conducted under DEQ authority with final cleanup objections and making the determination as to whether further action is warranted. Where early source control actions meet the requirements of the ROD, then EPA will not require further action to be taken in those areas. There may be upland groundwater plumes that are beyond the upland control point that may need further control in the river (sediment cap or amendment to a sediment cap) which will be accounted for during site-specific designs.

The remedial design for in-river actions will evaluate site-specific information in detail. The remedial design will include an evaluation of the completeness of the site-specific groundwater pathway and effectiveness of SCMs which have been implemented at each facility. The ROD includes a simplified and flexible decision tree which will dictate the design and remedial construction and is intended to provide a clear direction on what action should be taken under different environmental conditions and locations, which may include design needs that apply upland and in water to ensure a comprehensive site remedy that will meet cleanup levels.

### **4.1.12 Clarify Oregon Marine Board’s Authority and Role in Implementation**

#### **Comment**

The proposed plan states: “Where caps will be utilized to contain contamination in navigable areas of the river, waterway use restrictions or RNAs [regulated navigation areas] will be necessary to ensure the integrity of the cap is maintained in perpetuity. These restrictions would preclude boat anchoring and keel dragging, the use of spuds to stabilize vessels, structure and utility maintenance and repair, and future maintenance dredging in areas containing caps. Notifications such as signs and buoys placed by the Oregon Marine Board may be used to warn vessels away from the area.” This language is incorrect - the Marine Board does not have the authorities described in the proposed plan.

The role of the Oregon Marine Board should be clarified by:

- Explaining that the Marine Board will not purchase or place signs and buoys, as this is the responsibility of the applicant for a waterway marker permit. The Marine Board Waterway Marker Permit is required in addition to the Private Aid To Navigation (PATON) permit required by the US Coast Guard. The Marine Board will approve the placement of waterway markers through the waterway marker permit application process, provided that the regulation listed on the waterway marker is adopted in code, statute or rule to be enforceable.

- Specifying which enforcement agency (US Coast Guard or State of Oregon) will be responsible for enforcing any new regulated navigation areas. Any lead agency will need to propose and adopt regulations accordingly, either in federal code, state law or both.
- Allocating adequate funding to pay for enforcement of regulated navigation areas “in perpetuity.”
- Acknowledging that slow-no-wake safety zones required for in-river work or near-water work must be adopted in state rule or statute to be enforced by the state. The Marine Board requires prior notice and planning as to how the zones will be marked for enforcement to occur. Any contractor doing in-river or shoreline work will need to pay for waterway markers and dedicated work-zone enforcement from marine patrol as the buoys and hours will not be paid for by Multnomah County or the Oregon Marine Board.

### **EPA Response**

EPA acknowledges the misstatement regarding the role of the Oregon Marine Board in placement of waterway markers. The ROD does not say the Board has enforcement authority. The enforcement of RNA-related ICs with respect to the governmental entity that will provide enforcement authority will be determined during the development of remedial design and identification of responsibilities in an ICs implementation and assurance plan and operation and maintenance plan to be developed in coordination with federal agencies (such as EPA, USCG, etc.) and the appropriate agencies from the State of Oregon. Funding for IC planning activities will be worked out during negotiations with performing parties.

### **4.1.13 Recognize Department of State Lands’ Authority and Role in Implementation**

#### **Comment**

Oregon Department of State Lands manages state-owned submerged and submersible land, which the state holds in trust for the public<sup>6</sup>. The use of state-owned land in conjunction with remedial activity is governed primarily by Oregon Administrative Rules Chapter 141 Division 145 (effective February 2014). These rules describe the process by which Oregon Department of State Lands will determine the compensation due the state for the required use authorizations. This determination requires calculation of the “Site Diminishment Impact” (or SDI) of the proposed remedial action based on its anticipated impacts on public trust uses, the duration of those impacts, and the extent to which the remedial action will impair the Department’s ability to manage the affected land in the future. Greater impacts or restrictions on public trust uses of state-owned submerged and submersible land will compel greater compensation.

Performing parties will need to coordinate with Department of State Lands. This process should begin prior to remedial design so that input can be considered and incorporated into that design. Early review of remedial design will facilitate a more accurate estimate of the required compensation and may help identify potential options for reducing that compensation. For example, cap design (e.g. location, thickness, material, etc.) that minimizes the impact to public trust uses (e.g. does not prevent or impair anchoring, fishing, or motor usage) will require less compensation to the state than a cap that restricts public trust uses or impedes Department’s ability to lease the property in the future (e.g. restrictions on driving pile, placing docks, etc.). Similarly, a number of small caps in close proximity may impose greater impacts on public trust uses than each cap would have when viewed in isolation. Cumulative impact will be considered in calculating the SDI of each cap, and may impact the

compensation due. (A large number of small caps will also increase the tracking, monitoring and enforcement workload for Oregon Department of State Lands and other agencies and, for that reason, is not favored.)

The proposed plan does not include the cost of Department of State Lands use authorizations, which could range as high as \$15 million harbor-wide (reflecting a site-wide average of roughly \$230,000/acre) for sediment cap easements alone, and have the potential to affect the evaluation of relative costs in selecting between capping and dredging technologies.

The role of Department of State Lands should be clarified by:

- Expressly recognizing the state’s land management role in remedy implementation, specifically their role in authorizing the use of state-owned submerged and submersible land for remedial activities.
- Identifying the potential costs associated with use authorizations, recognizing that these costs can be most effectively managed by their consideration in the early stages of remedial design, and in consultation with the Department of State Lands.
- Providing flexibility during remedial design such that performing parties can, consistent with remedial action objectives, reduce or eliminate impacts to and restrictions on public trust uses of state-owned submerged and submersible land, including by switching from capping to dredging.

### **EPA Response**

Department of State Lands propriety authorizations, which include lease fees, were not included in the cost estimates. EPA acknowledges that the State Land Board through the Department of State Lands-promulgated rules for granting and renewal of access authorizations, leases, and easements issued to facilitate remediation conducted pursuant to an order issued by DEQ or EPA and habitat restoration activities in, on, under or over state-owned submerged and submersible land. However, Section 104 of CERCLA, 42 U.S.C. § 9604 provides the President with broad authority to take response actions determined necessary to protect the public welfare and the environment from releases or the potential threat of a release of hazardous substances or pollutants and contaminants to the environment presenting an imminent and substantial endangerment to public health and welfare.

Section 104(e)(3) specifically provides the President authority to access “[a]ny vessel, facility, establishment, or other place or property where entry is needed to determine the need for response or the appropriate response or to effectuate a response action under” CERCLA. 42 U.S.C. § 9604(e)(3). Furthermore, Section 121(e)(1) of CERCLA provides that: “[n]o federal, state, or local permit shall be required for the portion of any removal or remedial action conducted entirely onsite, where such remedial action is selected and carried out in compliance with” CERCLA. 42 U.S.C. § 9621(e)(1). If EPA were to perform the remedy, the United States would not be required to pay state fees. However, EPA expects most, if not all, of the remedy (cleanup actions) will be performed by PRPs and EPA anticipates that PRPs will negotiate reasonable terms and conditions of access to private and state-owned property to implement the remedy likely with landowners and Department of State Lands. The selected remedy overall is expected to improve the sediment and surface water quality of the river. EPA’s selected remedy seeks to minimize land and river use restrictions, while also assuring long-term protectiveness and a cost-effective cleanup. EPA encourages performing PRPs to coordinate with

Department of State Lands early during remedial design to negotiate access and find further ways to reduce land and river use restrictions and, if relevant, diminution of property values.

During design, additional data will be collected that will identify where dredging and capping should occur within the Site and this sampling will occur with much more detail than previous sampling. Contaminant concentration data will be used to identify where capping or dredging should occur. Identifying whether capping or dredging is most appropriate for an area will be determined based on location-specific land uses and river conditions and whether or not the material can be effectively contained with a cap. If it is possible to cap the contamination, a cap likely will be used. If a cap is not appropriate based on land/river uses or water level depth, wind or wave action, dredging will likely be the technology applied. Depth of dredge will be based on depth of contamination and whether a cap could be incorporated into the design. In the feasibility study, it was determined that capping was not appropriate for areas that would be dredged for navigation and ship berthing and there were assumptions about where this kind of activity occurred. During design, these areas will be more accurately identified and where maintenance dredging is not a reasonably anticipated future use, the remedy will be adjusted and capping could be used instead of dredging.

#### 4.1.14 Clarify Oregon Health Authority's Role in Developing and Implementing Fish Advisories

##### Comment

All existing fish advisories in Oregon were developed and issued by the Oregon Health Authority using EPA guidance. They typically communicate these advisories via news releases and its website. In some cases, local health authorities or local water body managers post signs on behalf of Oregon Health Authority. Generally speaking, county health departments are the most appropriate entity to conduct outreach and community engagement for local public health issues; however, they often lack the staff capacity and funding to do so for environmental health issues. Portland Harbor is located within the Multnomah County's jurisdiction. With the appropriate level of resources, Multnomah County Health Department would be the entity to implement a fish advisory outreach program for Portland Harbor.

The role of Oregon Health Authority should be clarified by:

- Specifying the role of state and local health authorities in developing and implementing fish advisories.
- Identifying the resources and funding that EPA will provide to state and local health authorities for conducting effective community outreach and education.

##### EPA Response

EPA explained the need for fish consumption advisories in both the feasibility study and the proposed plan (USEPA 2016c) based on the results of the BHHRA (Kennedy/Jenks 2013) in the remedial investigation report (USEPA 2016a). EPA has clearly identified in the ROD the need for fish consumption advisories during and after construction of the remedy until cleanup levels are achieved. Even then, watershed-wide fish consumption advisories such as the existing Oregon Health Authority advisory may need to remain in place because there are sources of contamination that are outside of the scope of the Superfund cleanup (such as upstream sources of naturally-occurring mercury).

EPA recognizes that fish consumption advisories are more effective with community support. During remedial design, EPA will develop an ICs implementation and assurance plan that lays out the approach for the development and implementation of all ICs required by the ROD to protect humans

from exposure to site contaminants and to protect the remedy put into place. Specifically, the use of fish consumption advisories and RNAs, and the entities responsible for implementing them. Additional IC mechanisms may be developed during remedial design, as needed.

The primary goal of the ICs implementation and assurance plan is to establish and document the activities necessary to implement and ensure the long-term stewardship of ICs, and specify the persons and/or organizations that will be responsible for conducting these activities. In development of the ICs implementation and assurance Plan, EPA will coordinate with river users, property owners, communities and other stakeholder groups to minimize the long-term impacts of ICs as part of the remedial action.

The approach for the fish consumption advisory IC will likely include, but not be limited to, the following:

- Survey fisher communities, including Tribal, low-income, minority, and immigrant communities, to verify the fish species being consumed, consumption rates, preparation and cooking practices
- Develop a fish tissue sampling plan including species, numbers, and size of fish to be sampled, as well as tissue surrogates, such as passive sampling devices, where needed
- Use fish tissue and other empirical data to support the five-year review process in evaluating the relative success of remedial measures against RAOs
- Collect fish tissue data during remedial design (baseline) and throughout construction as part of the comprehensive monitoring plan for the Site
- Establish fish consumption advisories that are fully protective of human health throughout construction and following construction based on on-going monitoring of fish tissue samples from upstream, within, and downstream of the Site
- Conduct outreach and education tailored to the affected communities to ensure that fish consumption advisories are effective and appropriate, advisory signs are designed, installed, and maintained effectively and at the appropriate locations, in coordination with Oregon Health Authority and Multnomah County Department of Health. Programs such as the education collaborative at Palos Verdes will be considered in development of the ICs implementation and assurance plan.
- Identify and educate fisher communities about mechanisms to reduce the impacts of fish consumption. The Agency for Toxic Substances and Disease Registry and/or Oregon Health Authority will review fish consumption information from EPA in their health assessment process, and offer health screenings if appropriate.
- Include coordination with sport or recreational fishing clubs and licensing locations
- Monitor the effectiveness of fish consumption advisories through surveys of fisher communities during construction
- Based on long-term monitoring as determined in the five-year review process required under CERCLA, re-evaluate fish consumption advisories to ensure they are fully protective but not overly restrictive and on target to meet long-term goals of the remedial action. This may include

special consideration of high use areas such as beaches and fishing areas at Cathedral Park, Willamette Cove, and Swan Island Lagoon.

## 4.2 Specific Text Concerns

### 4.2.1 River Bank Region, Page 12

#### **Comment**

The ROD should clearly define the term river bank and clarify whether the term applies to either a geomorphic feature or specified elevation.

#### **EPA Response**

The ROD defines river banks as top of bank down to the river.

### 4.2.2 Assumptions for Fish Consumption Rates and Patterns, Page 17

#### **Comment**

The ROD should make a distinction between anadromous species and resident species. Spring Chinook, steelhead, coho, shad, and lamprey are anadromous species likely have lower contaminant levels and are targeted by a wider and more diverse group of anglers. Resident fish like crappie, smallmouth bass, carp, bullhead, catfish have higher levels of contamination because their range is within Portland Harbor and these type of fish are more targeted by and more likely to be eaten by local residents.

#### **EPA Response**

EPA agrees that risk communication must be clear as to the types of fish that are unsafe to eat. The ROD and subsequent ICs implementation and assurance plan documents and advisories will distinguish between anadromous species and resident species with regard to fish consumption advisories.

### 4.2.3 Baseline Ecological Risk Assessment, Page 20

#### **Comment**

The ROD should specify that TPH is both TPH-Diesel as measured by the TPH-Diesel method and as the aliphatic EC10-EC12 fraction.

#### **EPA Response**

Due to the detections of TPH Diesel in groundwater and pore water at the Site and because the target reference value for C10 – C12 aliphatic hydrocarbons represents both the upper end of gasoline range hydrocarbons and the lower end of diesel range hydrocarbons, the target reference value for C10 – C12 aliphatic hydrocarbons was selected as the PRG in the feasibility study and now the cleanup level in the ROD.

### 4.2.4 Reactive Caps, Page 27

#### **Comment**

The ROD should describe the purpose and function of organoclay versus activated carbon, particularly with respect to effectiveness with NAPL.

**EPA Response**

Organoclay has a lower permeability than carbon and used to retard seepage velocity where groundwater plumes are suspected to be present. As discussed in Appendix D4 this low permeable material is used for significantly augmented reactive caps.

**4.2.5 Productivity, Page 29****Comment**

The Plan assumes a dredging season based on one in-river work period (July 1 through October 31). The ROD should acknowledge that there is a second in-river work period in the winter (December 1 to January 31st) and identify what, if any work, may be done during this period.

**EPA Response**

EPA will continue coordination with NMFS with regard to what in-river work activities, if any, would be allowed during the second in-river work period as well as any flexibility that might occur seasonally in the summer work window.

**4.2.6 Potential Contaminant Release during Construction, Page 29****Comment**

The ROD should include a statement that acknowledges the limitations of silt curtains and sheet pile walls.

**EPA Response**

Water quality controls, including silt curtains and/or sheet pile wall enclosures will be required to minimize releases to the water column associated with the presence of contaminated sediments, NAPL, debris and other chemical or physical conditions. The ROD addresses limitations of these water quality control systems. Various water quality controls will be evaluated on location specific basis during remedial design, given the variability of subaqueous conditions within the harbor. Details regarding sediment dispersion control and location-specific engineered rigid control measures will be determined during remedial design. Refer *Final GASCO Oversight Report, November 2006*, for various limitations in effective implementation of silt curtain system.

**4.2.7 Dredge Residuals, Page 29****Comment**

The plan states that “A 12-inch sand layer is assumed to be placed daily in all dredge areas to control residuals and releases.” Daily placement of a residuals management layer is not practical and would have significant impact on the project schedule and costs with limited benefits. DEQ recommends placement of a single 12-inch dredge residuals management layer following dredging.

**EPA Response**

EPA agrees that residual management layers should be placed as soon as is practicable following dredging but likely not as often as on a daily basis.

**4.2.8 Buried Debris and Piling, Page 29****Comment**

The ROD should clarify whether debris removal will be required in capping areas and how debris may influence the technology assignment for dredging versus capping. In particular, there tends to be heavy debris in the intermediate and shallow water areas and along the river banks, which will hamper the efficacy of pre-dredging in these areas.

**EPA Response**

During remedial design, debris and other area-specific features will be evaluated. The decision tree in the ROD has been revised to clearly outline this process. Also, EPA agrees that maintaining flexibility in construction methods through the remedial design phase is an important consideration, particularly for nearshore areas near structures and area with debris.

**4.2.9 Fish Advisories and Educational Outreach, Page 32****Comment**

EPA should avoid issuing consumption advice with a time denominator greater than 1 month. For example, if the calculated meal recommendation is 6 meals in 10 years, the advisory should say no resident fish consumption. The main reason for this is clarity and usefulness of the information for the general public. Typical fishers are unlikely to keep track of their consumption of fish from a specific water body over a 10 year, or even 6 months, period. As a matter of practical risk communication, any recommendation that is more restrictive than 1 meal per month should be communicated as no fish consumption. The current fish advisory for Portland Harbor is zero meals per month for sensitive groups, especially pregnant and nursing women, and one meal per month for everyone else. Oregon Health Authority recognizes that the current recommendation is inconsistent with fish tissue data that have been collected and current fish advisory calculation methodologies. The current fish consumption advisory for Portland Harbor will be updated to recommend no consumption of resident fish. This adjustment will bring Oregon Health Authority's advisory into alignment with EPA's recommendation.

**EPA Response**

EPA agrees fish advisory information should be as clear as possible and an ICs implementation and assurance plan will lay out the approach for the development and implementation of ICs, including fish consumption advisories and timeframes with this in mind.

**4.2.10 River Banks, Page 36****Comment**

The Plan states that "The technology assignments for SMAs adjacent to identified contaminated river banks are extended to include those river banks." This is in conflict with the next sentence which states that "Where SMAs are projected onto the river bank, removal followed by capping is the assigned remedial technology." The ROD should clarify the technology assignment for river banks and should explain how river banks action will be integrated with ongoing source control efforts.

**EPA Response**

The updated technology assignment decision tree for decision making is included in the ROD. The ROD includes the flexibility for the remedial design to evaluate and select the appropriate remedial technologies. The remedial design will need to address site-specific factors such as highly toxic PTW, depth of excavation, on-site structures, site operations, habitat, and other site-specific features.

**4.2.11 Long-Term Effectiveness and Permanence, Pages 52 through 55****Comment**

The definitions of residual risk and post-construction risk are unclear. The ROD should clarify these terms and how the risks associated with each are calculated.

**EPA Response**

Residual risk is defined as the cancer risk or hazard index once the PRGs are achieved. Because not all selected PRGs are risk-based, the residual risk or HQ for individual COCs may be greater than the  $1 \times 10^{-6}$  cancer risk or HQ of 1 used to calculate risk-based PRGs. Also, the magnitude of residual risk for Portland Harbor is defined as the estimated residual risk based on the cleanup levels and is RAO specific.

Post-construction risks were calculated for RAOs 1, 2, 4, 5, 6 and 8 for each for each alternative carried through the detailed analysis. These evaluations required estimates of surface sediment concentrations averaged on the following spatial scales: rolling river mile concentrations averaged over 0.5 river miles for only the eastern and western nearshore river segments and Swan Island Lagoon, rolling river mile average concentrations for each river segment, SDU-scale SWACs, and a site-wide weighted average concentration for each COC. All post-construction risks are evaluated as only the contribution from the sediment.

Refer to Appendix J of 2016 feasibility study report (USEPA 2016b) for more details regarding how “Residual Risk and Post-Construction Risk” were estimated or calculated. Refer to Section 11 of the ROD for the summary of each alternative where they are evaluated to determine how, at the end of cleanup construction, each alternative compares to the residual risk and post-construction risk. Each alternative was evaluated to compare the estimated risks remaining at the end of cleanup construction, as well as when cleanup levels are achieved. The risk remaining once the cleanup level is achieved is called residual risk. Table 22 in Appendix II of the ROD provides the calculated risks at the end of construction for each alternative. Alternatives with smaller SMA footprints have higher risks post construction to human health and the environment, address less groundwater contamination, and include fewer contaminated river banks. Alternatives that have smaller cap/dredge footprints and rely more on MNR have more uncertainty that cleanup levels would be met.

**4.2.12 RAO 2, Page 51****Comment**

The interim target hazard index for infants is stated as 1,250 on a site-wide scale and 920 on a river mile scale. These targets are inconsistent with the feasibility study report. The infant interim target hazard index in the feasibility study report is 1320 site-wide and 450 on a river mile scale (see feasibility study report Page 4-79).

**EPA Response**

The interim targets based on the infant nursing exposure scenario were calculated based on the selected PRGs for RAO 2. Residual risk estimates were calculated as presented in Table J1-2 in Appendix J of the feasibility study report (USEPA 2016b). The interim targets were calculated by multiplying the residual risk estimates of 132 (site-wide) and 45 (RM and SDU scale) by 10. The residual risk estimates exceed 1 because many of the PRGs for RAO 2 are not risk-based but rather based on background. Cleanup levels for each RAO will be evaluated against empirical data collected under a robust monitoring plan for the Site.

**4.2.13 RAO 5, Page 51****Comment**

The interim target for RAO 5 is unclear. Although the text indicates that the interim target for RAO 5 is to address 50 percent of the benthic risk area, this is untrue. The Alternative I footprint addresses only 17 percent of the benthic risk area (225 acres, Table J2.4-1). Although not explained in the text, the

state understands that EPA's interim target is actually based on the area exceeding 10x the benthic risk PRGs. The basis for all interim targets should be clearly described in the text.

**EPA Response**

Refer LWG Dispute Issue 1b (Appendix A of this document). As shown in Table 22 of the ROD, EPA's selected remedy, Alternative F Modified, addresses 72 percent of the area with unacceptable benthic risks (the area that exceeds 10 times the benthic risk value). The Alternative F Modified achieves the interim target of 50 percent.

Alternative I addresses 64 percent of the area with unacceptable benthic risks (Figure 4.2-29 and Table 4.2-7), which achieves the interim target of 50 percent.

#### 4.2.14 Implementability, Page 56

**Comment**

The ROD should acknowledge potential impacts of construction on adjacent business and marine-based commerce and consider these impacts in the comparative alternatives evaluation. Alternatives which can be implemented in a shorter period of time will have a shorter duration of impacts.

**EPA Response**

Because the primary objective of the remedy must be to protect of human health and the environment, economic impacts to businesses are not considered in the CERCLA alternative evaluation and remedy selection process directly or specifically. However, EPA recognizes the goal to limit interference with commercial, industrial, and other uses of the river to the extent possible and will take into consideration those operations and constraints during remedial design. EPA will work with landowners and businesses to minimize economic impacts through the design and implementation of the remedial actions.

#### 4.2.15 Preferred Alternative, Page 64

**Comment**

The plan calls for placement of an impermeable cap layer (e.g., AquaBlok) beneath structures. This type of cap may be subject to failure and heaving due to tidal influences and surface water-groundwater exchange, resulting in some loss of its isolation capabilities. Other cap materials should be considered and evaluated during design for placement under structures.

**EPA Response**

As discussed in the first square bullet on Page 64 of the proposed plan (USEPA 2016c), AquaBlok™ was assumed to be a representative material for feasibility study evaluation and feasibility study cost purposes that could be used to reduce cap thickness under structures. However, EPA agrees that other comparable materials could achieve the objectives identified for AquaBlock™ as discussed on Page 64 of the proposed plan could be considered and evaluated during remedial design. The ROD includes "or similar" type language when referring to such proprietary technologies.

The ROD includes a flexible decision tree along with general capping design requirements to guide the assignment of capping technologies, based on specific characteristics within SMAs. The decision tree will be used during remedial design to define what actions should be taken under different environmental conditions and locations based on the most recent design data. Once the data and river factors are evaluated within the context of the decision tree, a final design for construction can be

completed. This design will then dictate the remedial construction. The decision tree is intended to provide clear direction on what actions should be taken under the different environmental conditions.

#### 4.2.16 Preferred Alternative, Page 65

##### Comment

Aquablok and Aquagate are proprietary products. The use of these products should not be a specific requirement and the ROD should clarify that alternative, comparable products may be used.

##### EPA Response

As discussed in the first square bullet on Page 64 of the proposed plan (USEPA 2016c), a reactive layer was discussed for use in addressing groundwater plumes where pore water exceeds PRGs. The representative materials discussed as an assumption for the feasibility study report (USEPA 2016b) for evaluation purposes was AquaGate and Aquablok™. However, EPA agrees that other comparable materials that could achieve the objectives of a reactive layer as discussed on Page 64 of the proposed plan could be considered and evaluated during remedial design. The ROD includes “or similar” type language when referring to such proprietary technologies.

### 4.3 Specific Issues with Figures and Tables

#### 4.3.1 General

##### Comment

The ROD should provide adequate depictions of the risk areas to be addressed by the remedy.

##### EPA Response

The feasibility study report (USEPA 2016b) has depictions of the RAO 5 risk areas addressed with each of the alternatives as shown in Figures 4.2-19, 4.2-21, 4.2-23, 4.2-25, 4.2-27, 4.2-29. A similar figure will be developed for the final chosen alternative and presented in the ROD. It should be pointed out that these areas will change as new data are gathered.

#### 4.3.2 Figure 6

##### Comment

The river banks identified as contaminated in this figure should be revised to be consistent with the areas identified in the Portland Harbor Upland Source Control Summary Report March 25, 2016.

##### EPA Response

See River Banks Theme 10: “The completeness of river bank contaminant delineation and the need for an action to address river bank soil will be evaluated during remedial design.”

#### 4.3.3 Figure 10a

##### Comment

This figure assumes that no PTW or RAL exceedances occur greater than 18 feet bml in FMD areas or 15 ft bml in the navigation channel. It is unclear whether these depths define the maximum dredge depths in these areas, or if dredging will extend to the full depth of PTW/RALs should new data indicate deeper exceedances.

##### EPA Response

Section 14.2.9.1 of the ROD states “If caps are required within the navigation channel and future maintenance dredge areas, work will be coordinated with USACE to ensure that the cap is compatible

with current and anticipated waterway use. Any proposed capping in the navigation channel and future maintenance dredge areas will consider the current and authorized channel depth, the potential for an increase to the currently authorized channel depth, future navigation and maintenance dredging, and an appropriate buffer depth to ensure the integrity of the cap.” Section 15.2.3 of the ROD further states “Contaminated sediments located in the navigation channel are assumed to be dredged and then a residuals management layer will be placed in the dredged area. The Willamette River currently has an authorized channel depth of -40 ft CRD. Prior to listing of the Portland Harbor Superfund Site on the NPL, the USACE proposed deepening the federally maintained navigation channel to -43 ft CRD.

Contamination at depths greater than the authorized depth of the navigation channel may be capped and those caps will be constructed below the authorized depth of dredging so as not to interfere with future dredging as well as to provide an overdredge allowance or buffer zone, as necessary, to protect the remedy from future dredge activities.”

#### 4.3.4 Figure 10b

##### **Comment**

The multi-criteria design matrix (feasibility study report Figure 2.4-16) is necessary to interpret the intermediate area technology assignments. This matrix should be included and discussed in the ROD. This discussion should include a summary of the weighting and scaling approach used for various elements and should also acknowledge the dependence of the evaluation on assumptions such as the choice of cutoff criteria and the scale, and use equal weighting of factors on the resulting matrix designation. Alternatively, and preferred by the state, is that a preference not be specified between dredging versus capping in intermediate areas.

##### **EPA Response**

The decision tree used in the feasibility study report (USEPA 2016b) is not used in the ROD. Instead a more simplified and flexible decision tree is used and should address the above question. See Section 2.24 of this responsiveness summary for a detailed response on the use of assignment criteria and how dredging and capping will be addressed.

#### 4.3.5 Figure 19c

##### **Comment**

Alternative I identifies dredging as the remedial technology for the portion of Terminal 4, Slip 3 which was capped as part of the T-4 Phase I Removal Action. The ROD should either amend the figure if the assigned technology is in error or explain why the cap should be removed.

##### **EPA Response**

There is a small cap at the head of Slip 3 as shown in the Phase 1 Removal Action (2008 Anchor QEA). The technology assignments presented in the feasibility study report (USEPA 2016b) are representational and do not determine the final applications. The state of currently capped areas will be taken into account during final remediation design.

##### **Comment**

Beach sample locations adjacent to the Mar-Com North and South Parcels<sup>7</sup> indicate that PCBs in excess of the Alternative I RAL extend into the cove area outside of the Alternative I footprint shown in the figure.

**EPA Response**

Only sediment samples were used in the site evaluation. River bank and beach samples were not included. Final technology assignments will be evaluated based on new data and sampling collected during the remedial design phase. There will be an opportunity to decide on whether or not to include additional sample data and how best to evaluate it.

**4.3.6 Table 11 – PRGs****Comment**

- The table title and headers should distinguish between PRGs (sediment) and target values which will be used as a measure of progress (surface water, groundwater, fish/shellfish tissue).
- The groundwater PRG value of 2.6 µg/L for TPH-Diesel should be clarified as applying to the aliphatic EC10-EC12 fraction of TPH.
- The fish tissue values apply to both fish and shellfish.

**EPA Response**

EPA has revised the RG table in the ROD to distinguish between cleanup levels for RGs for surface water, groundwater and river bank soil/sediment and target levels for fish tissue. Target levels for fish tissue are generally based on fish consumption because the shellfish consumption rates are much lower than the fish consumption rates. The exception to this is cPAHs which has fish tissue target level of 7.1 µg/kg, based on a shellfish consumption rate of 3.3 grams per day. EPA has also clarified that the RG for TPH diesel in sediment is 91 milligrams per kilogram (RAO 5) and the PRG for C10 – C12 aliphatic hydrocarbons is 2.6 micrograms per liter (RAO 8).

The groundwater PRG of 2.6 micrograms per liter should be for C10 – C12 Aliphatic hydrocarbons and not TPH diesel. There is a PRG of 91 milligrams per kilogram for TPH-Diesel in sediment (RAO 5).

The shellfish consumption rates are much lower than fish. Fish and shellfish were evaluated separately. In general, the RAO 2 PRGs are based on fish consumption. The exception to this is the cPAH PRG which was based on clam consumption.

## Section 5

# National Marine Fisheries Service Comments and Responses

## 5.1 General Comments on the Proposed Plan

### 5.1.1 Consider Impacts to Trust Resources

#### Comment

“NMFS is concerned with potential impacts of the proposed plan to our trust resources, specifically:

- a. Habitat modification in the Harbor, changes in prey availability, and bioavailability and bioaccumulation of COCs in the prey species of out-migrating juvenile salmon and steelhead are all important threats to these species.
- b. Marine mammal species, particularly southern resident killer whales, feed on salmon from the Columbia River system. Because of the bioaccumulative nature of many of the COCs addressed in the proposed plan, potential short-term increases in bioavailability of COCs in the Harbor represent a risk concern for these species.
- c. Southern DPS green sturgeon is particularly susceptible to short-term increases in bioavailability of COCs.
- d. Southern DPS eulachon in the Columbia River are susceptible to impacts to prey availability and increased bioavailability and bioaccumulation of COCs in their prey.
- e. An increase in the migration of COCs to the estuary represents a potential risk to Essential Fish Habitat (EFH) for coastal pelagic and groundfish species.”

#### EPA Response

EPA appreciates NMFS' comments on the proposed plan (USEPA 2016c) and draft Programmatic Biological Assessment. EPA will continue to coordinate with NMFS to evaluate impacts on listed species and designated critical habitat. The Programmatic Biological Assessment outlines the best management practices and other measures to be implemented to avoid or minimize impacts. Additional species noted above will be added to the next version of Programmatic Biological Assessment sent to NMFS for review.

### 5.1.2 Address Impacts of Disturbed Sediments on Salmon and Steelhead

#### Comment

“Direct disturbance of sediments in the Harbor, either through dredging or capping, are likely to adversely affect Endangered Species Act-listed salmon and steelhead, depending on where such activities occur in the channel profile. The river regions identified by EPA do not correspond to the ecological significance certain areas have to specific species. Specifically:

- Loss of active channel margin (ACM) and shallow water habitat (SWH) due to bank.
- Armoring, development, channelization, and fill within the historic ACM and floodplain are key factors limiting the recovery of some Endangered Species Act-listed species in the Lower Willamette River (LWR) and Harbor.
- ACM refers to the part of the river’s edge that occurs at the interface of unwetted shoreline and shallow water, and occurs from ordinary high water (OHW) to ordinary low water (OLW).
- SHW refers to areas from the water’s edge out to a maximum depth of 15 feet below OLW.
- This corresponds with part or all of the following river regions identified in the proposed plan: Intermediate Region, Shallow Region, and River Bank Region.
- The proposed plan is likely to result in significant disturbance of ACM and SWH areas because the proposed plan emphasizes dredging and capping in the Shallow Region and River Bank Region to avoid changes in river flood storage and to comply with no net rise requirements.

NMFS strongly recommends further consideration of the remedial actions proposed for ACM and SWH habitats, including limits on sediment disturbance and conversion of such habitat from submerged to submersible lands, e.g.:

- i. Reducing the repose of shorelines and removal of streambank fill to expand the floodway and active channel.
- ii. More stringent work area isolation measures when dredging in shallow water habitats.
- iii. Provision of more a substantial “beach mix” to provide a habitat layer to enhance recovery of this key habitat type, e.g., (1) a mix of screened and washed 2.5-inch minus gravels (no fines) mixed with sand; and (2) use of a carbon-amended “beach mix” for broader expanse of ENR areas.

Because of the very high value of these areas for the survival and recovery of Endangered Species Act-listed species, NMFS favors ENR treatments over MNR in these areas.”

### **EPA Response**

EPA acknowledges the ecological importance of ACM and SWH areas. To avoid or minimize impacts on ACM and SWH areas, the feasibility study report (USEPA 2016b) Appendix L describes the following measures:

- Following dredging in shallow water areas (0 to 20 feet from ordinary low water), backfill would be used to restore the existing (pre-dredging) elevation to avoid loss of shallow water habitat.
- To offset permanent and/or temporal loss of habitat functions from dredging and capping in shallow water areas and as on-site mitigation, following dredging and capping in shallow water areas, slope would be laid back or the slope otherwise lessened to as close the existing slope as practicable given site-specific conditions.
- To further offset permanent and/or temporal loss of habitat functions from dredging and capping on river banks and as on-site mitigation, after soil removal on river banks, river bank

slopes would be laid back to as close as a 5H:1V slope as practicable given site-specific conditions.

- Capping in shallow areas would specify dredging of an equivalent cap thickness prior to placement to allow for a net zero bathymetry change and avoid loss of shallow water habitat.
- Engineered beach mix layer consisting of rounded gravel typically 2.5 inches or less as well as sand would be applied to the uppermost layer of all caps and dredge leave surfaces in shallow areas. This layer would provide appropriate substrate habitat for colonization by benthic organisms. Beach mix would not be applied to leave surfaces consisting of sand unless required due to changes in hydrodynamic conditions following remedial activities to ensure the layer will be stable over time. In addition, if beach mix is placed over riprap armoring, monitoring would be required to determine whether the site-specific conditions are conducive to maintaining the beach mix habitat layer over the riprap. If monitoring, test plot pilot study, or site-specific modeling demonstrate that a sand/gravel surface can be maintained long term, this may be considered by EPA when determining if the compensatory mitigation proposed during remedial design is adequate. Coordination will be ongoing with the Services regarding treatment material compatibility with habitat.
- Vegetation would be incorporated into caps placed on river banks where possible such as in off-channel areas that are not prone to erosion and with less steep slopes.

EPA will coordinate with NMFS during remedial design to refine the selection of construction methods and the measures for protection of listed species and aquatic habitat.

### 5.1.3 Conduct Reach-Wide Sediment Sampling in Lower Willamette River

#### Comment

“Sediment sampling and characterization. Before starting remedial activities, NMFS recommends repeating the reach-wide sediment sampling for the LWR, originally conducted in 2008 and analysis of the data collected to:

- Ascertain if MNR is observable at the decadal timeframe.
- Better assess upstream contributions to the LWR.
- Improve our understanding of sediment and contaminant mobility.”

#### EPA Response

The remedial technology assignments described in the proposed plan (USEPA 2016c) were based on contaminant concentrations and physical conditions such as areas of erosion/deposition, infrastructure such as docks and piers, and land and waterway use. During remedial design, detailed area-specific studies will be conducted to determine existing baseline conditions, including levels of contamination and to design how the cleanup will be conducted before the construction begins. Baseline sampling will include areas upstream and downstream of the Site.

### 5.1.4 Address Concerns About the CDF

#### Comment

NMFS remains concerned about the inclusion of the confined disposal facility (CDF) in the proposed action, both from the standpoint of the loss of 15 acres of aquatic habitat (including 3+ acres of shallow water and off-channel habitat), and from the long-term disposition of the facility.

- How will wastes that do not meet disposal requirements for the CDF be separated from wastes that meet CDF disposal criteria, particularly for dredge units where such COCs may be adjacent, co-mingled, or layered?
- What seismic design requirements will be applied to the CDF, and to armored and engineered caps?
- If soluble contaminants will be placed in the CDF, what additional design considerations are necessary to isolate the CDF from the aquatic environment (e.g. slurry wall, impermeable lining, impermeable cover, a pump-and-treat system to remove these COCs)?
- On the other hand, if soluble contaminants will be excluded from the CDF, how will such COCs be adequately excluded from the waste stream identified for CDF placement?
- How will EPA ensure that any loss of ACM and SWH will be off-set?

#### EPA Response

A CDF is no longer being considered as part of the remedy.

### 5.1.5 Explain Treatment of ARARs

#### Comment

Please explain how EPA will determine which ARARs it will either attain or waive as part of the proposed remedy.

#### EPA Response

As stated in Section 2.1.1 of the feasibility study report (USEPA 2016b), EPA does not currently have a basis for waiving any ARARs. Any ARAR waivers would have to be supported by a technical impracticability analysis or other ARAR waiver basis and documented in a ROD amendment. Section 12.2 of the ROD identifies the ARARs that will be met.

### 5.1.6 Use Rock and Gravel Instead of AquaBlocks

#### Comment

The preferred alternative indicates a preference for AquaBlocks for use as a sediment cap because these structures achieve greater armor protection in a thinner profile depth. However, NMFS does not support use of AquaBlocks and prefers rock and gravel armor layers, even if doing so results in additional dredge depth.

#### EPA Response

AquaBlok® is a patented, composite-aggregate technology resembling small stones and typically comprised of a dense aggregate core, clay or clay-sized materials, and polymers. It is used as an impermeable material for remedial sediment caps, not for armor protection. NMFS may be referring to concrete block structures (such as those used at the McCormick and Baxter site) that could be used instead of rock or gravel armor. EPA agrees that rock and gravel armor layers would be preferable

over concrete block structures and will further coordinate substrate specifications with NMFS during design.

## 5.2 Comments on the Programmatic Biological Opinion

### 5.2.1 Define ACM and SWH

#### Comment

“The definition of ACM and SWH should be defined throughout the PBA as noted above. The definitions provided in this letter are consistent with what the Portland Harbor Trustee Council (PHTC) is considering as SWH for their restoration projects in Portland Harbor, and with the definitions that NMFS will use to analyze the effects of the proposed plan on Endangered Species Act-listed species.”

#### EPA Response

Comment noted. EPA will revise the PBA accordingly.

### 5.2.2 Ensure Material Placed for Habitat Purposes is Stable over Time

#### Comment

NMFS is concerned about the long-term stability of any “fish friendly” layers that may be placed over sediment in the Harbor as part of the proposed plan. The PBA should make clear that any sand or “beach mix” layer that is placed for habitat purposes must stable over time, including use of reduced slopes as necessary.

#### EPA Response

Comment noted. Stability of the beach mix layer will be evaluated during remedial design and subsequent monitoring.

### 5.2.3 Consider Beach Mix or Sand Covers as a Minimization Measure

#### Comment

“Beach mix” or sand covers should be considered as a minimization measure outside of shallow water habitat as well to reduce mitigation requirements in deeper water and bank areas.

#### EPA Response

Comment noted. Beach mix or sand covers will be considered as a minimization measure in deeper water and bank areas.

### 5.2.4 Define Criteria for Measuring MNR Success

#### Comment

In Section 2.3.2, please define the criteria that EPA will use to determine whether MNR is successful or not, and thus whether additional active clean-up will be required. This must include the number of years beyond the seven years of construction that will elapse before making this determination.

#### EPA Response

Following construction, there will be long-term monitoring until the cleanup levels and associated RAOs are achieved and beyond. A monitoring plan will be developed during remedial design and incorporated into the PBA. Data on contaminant levels will be used for multiple purposes, such as to determine if MNR is taking place as expected or if any additional actions are required to achieve the

cleanup goals on the planned timeline. EPA will coordinate with NMFS on the progress on achieving remedial cleanup levels and achieving RAOs over time and if any additional actions might be needed to achieve them. Impacts of any additional measures will be coordinated with NMFS and supplements provided for the Biological Assessment, if needed.

### 5.2.5 Address Concerns with Loss of Habitat and Structural Integrity

#### Comment

As noted above, NMFS remains concerned about the inclusion of the CDF in the proposed action, both from the standpoint of the loss of aquatic habitat and structural integrity in a large seismic event. If the CDF is constructed, it should meet all water quality criteria at the point of discharge.

#### EPA Response

A CDF is no longer being considered as part of the remedy. The PBA will be revised accordingly.

### 5.2.6 Provide Details of Safe Fish Handling

#### Comment

Since the collection of biota for tissue sampling for MNR will likely harm or injure some salmon and steelhead, we will need more details on this procedure in the PBA such as number of sampling design, procedures for safe fish handling.

#### EPA Response

Comment noted. A detailed fish sampling plan will be included in future monitoring plans. EPA will coordinate with NMFS as details of the monitoring plans are developed.

### 5.2.7 Fix Non-Lower Willamette River Issues in Avoidance and Minimization Measures Section

#### Comment

The impact avoidance and minimization measures section seems to include some measures that, as currently worded, do not appear to apply to the LWR.

#### EPA Response

Comment noted. The impact avoidance and minimization measures section will be revised to omit measures that do not apply to the LWR.

### 5.2.8 Work with NMFS to Develop a Refined List of Pile Removal Practices

#### Comment

Some methods of pile removal proposed in the PBA, such as clamshell extraction, may cause more adverse impacts than leaving the pile in place. Please work with us to develop a more refined list of pile removal BMPs to include in your final PBA.

#### EPA Response

Comment noted. EPA will work with NMFS to refine the list of pile removal BMPs in the PBA and remedial design documents.

### 5.2.9 Refine the Description of the Action Area

#### Comment

Please refine the description of the action area to include all areas where contaminants may disperse downstream, areas that may be used for compensatory mitigation projects, and areas that will be used as shipping facilities or affected by ship traffic or other actions necessary to transport contaminated sediment to its eventual landfill destination. Also, note that additional impact avoidance and minimization measures may be necessary for the safe upstream transportation and handling of contaminated sediments.

#### EPA Response

Comment noted. EPA will work with NMFS to refine the description of the action area per NMFS' comment and to consider impact avoidance and minimization measures necessary for the safe transportation and handling of contaminated sediments.

### 5.2.10 State That Mitigation Will Occur as Close to Impact Area as Possible

#### Comment

NMFS has not yet determined whether to approve compensatory mitigation projects outside of the Portland Harbor Site, either upstream in the Willamette River or downstream in the Columbia River. NMFS will strongly prefer mitigation to be as close to the impact area as possible, and would appreciate this being explicitly stated as a preference in the PBA as well.

#### EPA Response

Comment noted.

### 5.2.11 Describe Compensatory Mitigation Process

#### Comment

The Programmatic Biological Assessment should mention the likely option of credit purchases from approved mitigation banks as an alternative to applicants constructing their own compensatory mitigation projects. In addition, compensatory mitigation would not just involve converting upland to shallow water areas as is stated in the PBA in several places.

#### EPA Response

Comment noted. EPA will revise the Programmatic Biological Assessment to mention credit purchases from Clean Water Act 404 approved mitigation banks as an alternative to applicants constructing their own compensatory mitigation projects. EPA will coordinate with NMFS as specific compensatory mitigation projects are proposed but at this time are not prepared to eliminate any potential "enhancement" or "creation" mitigation projects that converting upland to shallow water may meet under the Clean Water Act.

### 5.2.12 Discuss Effects of All Contaminants that Would Impact Salmon and Steelhead

#### Comment

Why are the effects of only certain chemical groups on salmon and steelhead discussed in the PBA? Are these the only ones expected to be mobilized so that salmon and steelhead are exposed during the

proposed action? The Programmatic Biological Assessment should discuss effects of all contaminants that would likely impact salmon and steelhead during remedial actions.

**EPA Response**

As described in Section 5.1.1.1 of the Programmatic Biological Assessment, the BERA (Windward 2013) found that the potential acute exposure of contaminants during dredging at the Site is likely associated with the three chemical groups evaluated in the PBA: PAHs, PCBs, and DDx compounds. The revised Programmatic Biological Assessment will incorporate additional information, as needed, on the effects of these and other contaminants that could be mobilized and effect listed species.

### 5.2.13 Consider Impacts of Large Ship Wakes

**Comment**

Please consider the impact of large ship wakes as part of the determination of where caps will likely have to be armored, and where "beach mix" is likely to stay in place. Otherwise, EPA is likely to underestimate the amount of compensatory mitigation required for armored caps in the Harbor.

**EPA Response**

Comment noted. Remedial design investigation will consider the impact of large ship wakes as part of the determination of where caps will need armoring and how wakes would affect the stability of the beach mix layer.

### 5.2.14 Address Dispersion of Contaminants During Remedial Dredging

**Comment**

Please include any information available on the dispersion of contaminants during remedial dredging, e.g., studies that show the likely concentration, fate and transport of contaminants that will disperse downstream during clean-up operations.

**EPA Response**

Comment noted. The draft PBA included information on the dispersion of contaminants (see Section 5.1.1.1 of this responsiveness summary) and suspended sediment during dredging (see Section 5.1.1.2 of this responsiveness summary). The revised PBA will include additional information, if available, on the dispersion of contaminants during remedial dredging and other remedial activities.

### 5.2.15 Refine the Description of the Action Area

**Comment**

Table 5.3 and Section 5.4.2 state that the proposed action "would adversely modify" critical habitat for LCR coho salmon. Please note that the correct determination here is the same as for the other Endangered Species Act-listed species.

**EPA Response**

Comment noted. The PBA will be revised with the correct determination.

### 5.2.16 Consider Bioaccumulation Impacts in Killer Whales

**Comment**

For the killer whale effects determination, the PBA states that transport of contaminants from the Site to the LCR would be negligible so salmonid prey of killer whales would be unlikely to be exposed to resuspended contaminants. However, that does not acknowledge that some prey of killer whales

would likely be exposed to contaminants during the clean-up, and the fundamental role that bioaccumulation of contaminants in the killer whale's food web play in limiting its recovery.

**EPA Response**

Comment noted. The evaluation of killer whale effects will be revised to include consideration of prey that is exposed during the cleanup and the role of bioaccumulation of contaminants in limiting the recovery of the species.

**5.2.17 Consider Vessel Strikes on Whales****Comment**

Widespread dredging and capping will require the mobilization of equipment from outside the local area. Vessel strikes on whales by equipment moved from Seattle/San Francisco/Long Beach should be considered in the section on interrelated and interdependent actions.

**EPA Response**

Comment noted. The evaluation of killer whale effects will be revised to include consideration of vessel strikes by equipment from outside the local area.

**5.2.18 Discuss Capture of the Proposed Plan in the Biological Opinion****Comment**

Finally, we need to discuss how the proposed plan can be captured most effectively and efficiently in a biological opinion.

**EPA Response**

Comment noted. EPA looks forward to continued coordination with NMFS in development of the PBA and any supplements and biological opinions on remedial actions.

Re: Portland Harbor Superfund Site Final Feasibility Study Dispute Decision

Dear Sirs:

This memorandum resolves three disputes related to EPA's final Feasibility Study ("Final FS") for the Portland Harbor Superfund Site. The disputes were initiated by several but not all Respondents to the administrative order on consent entitled *In the Matter of: Portland Harbor Superfund Site, Administrative Settlement Agreement and Order on Consent for Remedial Investigation/Feasibility Study*, U.S. EPA Docket Number CERCLA-10-2001-0240 (the "AOC") and dated October 23, 2001<sup>1</sup>. Arkema, Inc., Chevron U.S.A., Inc., Evraz Inc., N.A. Gunderson L.L.C., NW Natural, TOC Holdings Co., and Union Pacific Railroad Company (collectively the "Lower Willamette Group" or "LWG"); Legacy Site Services ("LSS") the agent for Arkema, Inc.; and the Union Pacific Railroad ("UPRR") initiated the LWG, LSS, and UPRR disputes by letters of June 22, 2016. Specific responses to each issue raised in the disputes are included in Appendix A.

---

<sup>1</sup> The signatories to the RI/FS AOC include Atofina Chemical, Inc., Chevron USA, Inc., Gunderson, Inc., Northwest Gas, City of Portland, Port of Portland, Time Oil Co., Conoco Phillips Company (formerly Tosco Corporation), Union Pacific Company, and Oregon Steel Mills, Inc.

LWG requests the following determination:

1. EPA's June 2016 FS should not be used as the basis for a Record of Decision ("ROD") for the Portland Harbor Superfund Site.
2. The alternatives analysis in the LWG's 2012 FS provides an adequate basis for selecting a remedy at the Site.
3. LSS requests that EPA make several modifications to the Final FS as documented in its letter of dispute.
4. UPRR requests a determination that several elements of the Final FS fail to comply with the National Contingency Plan ("NCP"), 40 C.F.R. Part 300, and EPA's designation of principal threat waste ("PTW") at the Site.

By this memorandum I deny all relief requested in the June 22, 2016 letters of dispute. In so doing, I specifically determine that the EPA's FS is compliant with CERCLA and the NCP, and provides an appropriate basis for selecting a remedy in a ROD for the Portland Harbor Site.

#### Context

The FS disputes arise from EPA's decision of January 4, 2016 to finalize the FS for the Portland Harbor Superfund Site and to relieve the LWG of its obligation to complete performance of the FS. By letter of January 19, 2016, LWG disputed EPA's decisions regarding the FS and requested that EPA withdraw its letter. This dispute was resolved by an agreement of February 4, 2016 (the "February 4 Agreement") whereby LWG and EPA agreed, in relevant part, as follows:

1. The EPA will finalize the FS.
2. The LWG AOC signatories may dispute the Final FS produced by the EPA by submitting their dispute within 14 days of publication of the Proposed Plan.
3. The AOC dispute process would proceed directly to a formal determination by the Director of the Region 10 Office of Environmental Cleanup.
4. LWG's dispute statement will be placed in the administrative record and the dispute process will be conducted consistent with requirements for public participation for the proposed remedy decisions under CERCLA, the NCP, and federal law.

The EPA and LWG also anticipated that the determination resolving the dispute would be issued simultaneously with EPA's remedy decision after considering all public comments along with the disputed issues.

Prior to making this determination, I have reviewed materials I have received from the LWG, LSS, UPRR, and the EPA Portland Harbor Team that responded to the LWG, LSS and UPRR dispute

positions. These materials have also been placed in the administrative record that supports this Decision and in the Portland Harbor ROD Administrative Record.

### Scope of Dispute

The materials submitted and relied upon in the disputes are voluminous. EPA's position paper (Appendix A) which includes the LWG, LSS, and UPRR dispute positions, identifies and responds to over 50 issues. As an initial matter, I will streamline the dispute issue by addressing what issues are within the scope of the FS dispute. The February 4 Agreement allowed the LWG signatories to dispute the "Final FS." Issues related to EPA's decisions made prior to issuance of the Final FS (including those that have been resolved through the AOC's dispute resolution process or those relating to changes between EPA's draft 2015 FS and the Final FS) and the Proposed Plan are outside the scope of the February 4 Agreement and not subject to dispute.

In addition, a decision to exclude such issues from dispute is consistent with the AOC. This conclusion is supported by at least two sections of the AOC. The first is Section XII (Final RI/FS, Proposed Plan, Public Comment, Record of Decision and Administrative Record) of the AOC. In this section EPA, appropriately, retained the responsibility for preparing and releasing the Proposed Plan and Record of Decision. The second is Section XVIII (Dispute Resolution) of the AOC. Paragraph 1 of this section expressly limits disputes to activities or deliverables required under the AOC, prohibits disputes not initiated within 14 days of the disputed EPA decision, and renders a dispute resolution decision final (not subject to further review). Thus, the issues not related to the 2016 FS are dismissed without further discussion.

### Discussion

The LWG, LSS and UPRR collectively dispute nearly every aspect of the Final FS. They frame the issues within the rubrics of EPA's failure to comply with CERCLA, the NCP, and relevant EPA guidance; EPA's use of inadequate technical methodologies resulting in unsupportable determinations; or EPA's reliance on flawed data or assumptions, or conversely failure to rely on the right data or assumptions. Thus, and by way of illustration, the EPA is faulted for concluding that certain alternatives are not protective of human health and the environment or compliant with ARARs; exaggerating site contaminant risk, including those posed by eating fish; failing to recognize that upstream sediments are naturally covering up risks posed by contaminated sediment within the Site; ignoring, conversely, the potential for recontamination from upstream sources of contamination; determining incorrectly the types and amounts of PTW within the Site; underestimating the short term effects of dredging while overestimating the long-term benefits of cleanup, including erroneous assumptions about location and volume of waste subject to potential remedial action; relying on erroneous cost assumptions and underestimating the cost of remedy implementation; and ignoring the effect of source controls undertaken under the oversight of the Oregon Department of Environmental Quality ("ODEQ").

EPA's response addresses the dispute issues by clarifying misplaced suppositions that underlie Disputants' position, or by articulating a disagreement regarding the application of best professional judgment, or a combination of the two. EPA's response demonstrates that the EPA considered the relevant facts and drew logical conclusions from those relevant facts. Disputants may and do disagree with those conclusions, but EPA's conclusions are rationally related to the relevant facts and the product

of analysis based upon the EPA's experience of addressing widespread contamination at other sediment sites and sound scientific principles. Below are specific references to issues raised by the Disputants and the EPA's response which are illustrative of the information that supports my conclusion.

The LWG frames its first issue as follows: "EPA's conclusions that certain alternatives are not protective or fail to comply with ARARs are based upon evaluations that are inconsistent with the approved remedial investigation and baseline risk assessments and fail to apply appropriate risk management principles." In its response to this issue, the EPA addresses several sub-issues (LWG Dispute Issues 1a through 1s), and identifies where the LWG is mistaken, and where and why the EPA appropriately used its best professional judgment in a manner supportive of this decision. Some examples of EPA's responses to LWG Dispute Issue 1 include the following:

1. The EPA's response to LWG Dispute Issue 1a, which, among other things, describes why alternatives B and D are protective of human health<sup>2</sup> but are not protective of the environment; and unlike the Baseline Ecological Risk Assessment (BERA), LWG's proposed Comprehensive Benthic Risk Approach was disapproved by the EPA on December 18, 2012.
2. The EPA's response to LWG Dispute Issue 1b, which, among other things, describes how the EPA's approach to managing benthic risk "honors" data and information developed during the Remedial Investigation/Feasibility Study ("RI/FS"), and intends to protect local benthic populations.
3. The EPA's response to LWG Dispute Issue 1c, which, among other things, describes how EPA used surface weighted average concentrations (SWAC) in the Final FS. This approach addressed issues raised by EPA's National Remedy Review Board and EPA's Contaminated Sediment Technical Advisory Group. In addition, the approach EPA used in the Final FS provides a more realistic approach in managing risk than the approach proposed by the LWG in that the EPA's approach is consistent with the exposure of smaller range fish species that reside within the Site and takes into consideration the range within the Site these fish likely use.
4. The EPA's response to LWG Dispute Issue 1d, which, among other things, notes, in response to a complaint of the EPA's inappropriate reliance on aggregated data, that the EPA aggregated the same data as the LWG did in the draft FS it submitted to EPA in 2012, further describes the use of SWACs for evaluating alternatives during the Final FS, describes the use of interim goals as part of EPA's evaluation of long-term effectiveness by comparing post-construction risks to residual risks left if PRGs are met, and explains how site-specific considerations were sensibly used to develop remedial actions levels (RALs) to evaluate residual risk and allows the EPA to evaluate different arrays of cleanup actions and discern the relative cost-effectiveness each provided in risk reduction as part of the Final FS alternative analysis.
5. The EPA's response to the LWG Dispute 1m, which, among other things, describes how the EPA identified contaminants of concern (COCs) for surface water, informs why the identified surface water COC determinations are consistent with the CERCLA and the NCP, and explains why maximum contaminant levels (MCLs) established under the Safe Drinking Water Act are applied to pore water (both groundwater and surface water within the Site are potential sources of drinking water and pore water is representative of the pathway between the two).
6. The EPA's response to the LWG dispute 1q, which, among other things, explains why the EPA evaluated alternatives to address river bank contamination in the Final FS. In its explanation, the EPA notes the obvious, that contaminated river banks may be the source of a continuing release of

---

<sup>2</sup> The Portland Harbor Superfund Site ROD notes that alternative B and D may not be protective of human health since certain ARARs they may not attain are developed to be protective of human health.

hazardous substances into the waterway which may exacerbate existing contamination and re-contaminate remediated areas if not addressed, and describes the role of the ODEQ in EPA's decision to evaluate river bank contamination. The EPA also notes that it retains the authority to evaluate source control efforts undertaken under the oversight of ODEQ and that the Memorandum of Understanding between EPA and ODEQ does not preclude the EPA from exercising its authority.

7. The EPA's response to LWG Dispute Issue 1r, which among other things, describes the EPA's evaluation of post-construction equilibrium, and explains why, based on sediment trap data indicative of upstream sediment inputs and source control efforts, the EPA does not believe that remediated sediments will be re-contaminated.

The LWG's second issue argues that "EPA's June 2016 FS continues to lack complete and transparent evaluation of the long and short-term effectiveness of the alternatives, as well as the degree to which implementation of those alternatives will reduce the toxicity, mobility, or volume of hazardous substances, including through treatment of material it has labeled [PTW]." In response to the second issue, the EPA identifies and responds to numerous sub-issues, and in its response EPA, again, demonstrates that the LWG is either mistaken or that the EPA appropriately used its best professional judgment to address technical issues. Examples of responses include:

1. The Final FS relies on the conceptual site model developed in the RI report (which is not a subject of the Final FS disputes and was developed by LWG) and the Final FS provides the appropriate level of information related to the extent of contamination for the purpose of identifying and evaluating remedial alternatives. In addition, the EPA notes that the *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (2005), at pages 2-39 through 2-40, cautions against the use of models that cannot be calibrated and validated at the space and time scales associated with the questions the model must answer.
2. EPA also notes that the Disputants failed to develop, and have acknowledged their failure to develop, a calibrated and validated fate and transport model that could be used to evaluate post-cleanup effectiveness of different remedial alternatives.
3. EPA explains how its alternative analysis was both qualitative and quantitative.
4. EPA describes the role of cost-effectiveness in a feasibility study as the development and inclusion of information in a feasibility study that supports a cost-effectiveness determination when the remedy is selected, and how the Final FS includes the required analysis that supports a later determination of cost-effectiveness.
5. EPA describes the approach used for evaluating contaminant reductions in surface water that would result from implementation of the alternative remedial approaches, and explains why the assumption to subtract out upriver and downtown sources of contamination when evaluating alternative performance on reducing surface water contaminant concentrations is reasonable for the purpose of evaluating the effectiveness of different remedial approaches on post-cleanup surface water concentrations.
6. EPA acknowledges releases of dredged materials will occur during cleanup, estimates the released amount will equal approximately 1% of the dredged materials, and persuasively explains that this estimate is based on information developed during Phase 2 of the Hudson River project, and assumes use of best management practices that were developed for Phase 2 of the Hudson River project.

The Disputants raise and EPA responds to several issues related to cost assumptions used during the alternatives analysis. EPA's response includes, among other things, the following:

1. An explanation that the Final FS cost estimates were developed consistent with EPA guidance, *see A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* (July 2000), for the purpose of comparing remedial alternatives estimates and that the estimates EPA uses in the Final FS fit within the necessary +50 to -30 per cent range of actual costs.
2. EPA identifies cost components the Disputants believed were missing (e.g., multipliers that account for pre-design, initial condition assessment, and agency oversight, and the cost of water treatment associated with dredging).
3. EPA explains why economies of scale associated with a large cleanup likely result in lower assumed rates for certain categories of costs (e.g., contingencies, project management, project design, or the mobilization/demobilization cost multiplier).
4. EPA provides examples of when it used the same cost assumptions as those used to support the LWG 2012 draft FS (e.g., alternative specific costs for purchasing, installing and removing sheet pile walls as well as the unit cost allowance for environmental monitoring during offloading at a transload facility).
5. EPA explains the basis for assumptions that are relevant to cost and differ from those that the Disputants supported, e.g., dredging production rates, the discount rate used to calculate present value of the evaluated remedial alternatives, and the volume of PTW requiring treatment.

Each of the disputes raise issues related to EPA's treatment of PTW in the Final FS. The Disputants argue that EPA's approach to PTW is inconsistent with guidance because it designates as PTW areas with "relatively low concentrations of contaminants of concern" based primarily on EPA evaluation of risks posed by the consumption of fish caught at the Site, because it includes as PTW wastes that can be reliably contained, or because it incorrectly designates listed wastes. EPA responses on this subject articulate a well-reasoned application of professional judgment in its application of Site-specific considerations and relevant EPA guidance. EPA's responses include the following:

1. EPA notes the NCP at 40 C.F.R. § 300.430(a)(1)(iii)(B) specifies a preference for treating PTW whenever practical, and that the relevant EPA guidance, *see, A Guide to Principal Threat and Low-Level Threat Wastes* (Superfund Publication 9380.06FS, November 1991 at p. 2) provides that PTW "are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur."
2. EPA interprets, consistent with EPA practice, the above quoted language to create two categories of PTW. The first includes highly toxic source materials. The second encompasses source materials that are highly mobile that generally cannot be reliably contained or would present significant risk to human health or the environment should exposure occur.
3. EPA explains that its site-specific determination of highly toxic PTW at the Site includes several individual contaminants -- PCBs, cPAHs, DDx, and dioxins/furans (2,3,7,8-TCDD, 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, and 1,2,3,4,6,7,8-HxCDF) -- that above specified concentrations in sediment pose a  $1 \times 10^{-3}$  risk for cancer from eating fish caught within the Site and the toxicity values are based on information developed during the baseline human health risk assessment and its application of the food web model (FWM).

4. EPA evaluated several contaminants of concern for the purpose of determining whether they should be treated as PTW under the second prong of the PTW definition; and EPA made a site-specific determination that PTW also included non-aqueous phase liquid (NAPL) in the form of naphthalene associated with MGP waste and chlorobenzene, since naphthalene/MGP and chlorobenzene NAPL cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur.

Last of all, I will address concerns related to remedy implementation. These concerns are not within the scope of the disputes at issue but appear important to the Disputants and suggest that the Disputants mistakenly concluded that the Final FS identified the areas of contamination that will be subject to remediation and how each area would be remediated.

The Final FS relies on a large body of information developed during the RI/FS which provides an appropriate basis for identifying and evaluating remedial alternatives. However, and as noted by the EPA in its dispute response, the relied upon information was not developed with the intent to direct remedy implementation actions. Instead, the EPA used the information to support remedy selection by developing remedial alternatives for evaluation pursuant to CERCLA and the NCP's remedy selection criteria. In so doing, EPA, based on the best available information, made assumptions about the location of contamination and how it would be addressed. There is nothing unusual about EPA's approach in this instance. In almost every remedial cleanup the information developed during the RI/FS is supplemented by information that is developed post-ROD through remedial design studies, pilot or treatability studies, and remedy implementation.

This decision is issued concurrent with the Portland Harbor Superfund Site ROD. The Portland Harbor ROD, particularly in Section 14, explains where and how the remedy will be implemented by identifying post-ROD data gathering and monitoring activities, and describing factors that will be relevant to remedy implementation. I anticipate that the parties who perform post-ROD cleanup work will be involved in the development of post-ROD data gathering plans, monitoring plans and remedy implementation strategy.

The ROD identifies three phases of monitoring – baseline and remedial design data collection, construction monitoring, and long-term monitoring. The baseline and remedial design data collection discussion is most relevant to remedy implementation. This data collection effort will include, for example, the collection of surface sediment, sub-surface sediment, river bank, surface water, sediment pore water, groundwater, and fish tissue samples. In addition, and during the same period, data will be collected to refine the understanding of the Site bathymetry, inform flood-rise monitoring, identify NAPL, and update EPA's understanding of reasonably anticipated future uses within and along the waterway and ensure that implemented remedies are consistent with these uses. This new information will inform the implementation of the Selected Remedy decision tree and may result in implementation of different remedial technologies in different footprints than those mapped in the Final FS. For example, dredging and capping will be implemented in areas where the new information identifies exceedances of the RALs, and these areas may differ from those that were assumed to be dredged or capped in the Final FS.

The ROD recognizes that the Selected Remedy may need to be implemented in phases and/or work sequenced and identifies factors the EPA will consider to implement the remedy. These factors include, at a minimum, source control actions, recontamination potential, scope (size) of actions across the Site, impacts to river users and the community, seasonal weather impacts, fish windows, and the implementation approach proposed by parties who agree to implement the Selected Remedy. While no such decisions have been made, the Site may be divided into work areas for purposes of design and construction activities based on factors such as prioritization of significant source areas, logistics, efficiency, or other factors; and sequencing of cleanup work may consider factors such as potential impacts of upstream work on downstream areas, including but not limited to, the potential for resuspension of contaminants during construction, nature and extent of contamination, and integration of the cleanup actions into the overall Site remedy.

The ROD makes clear that the manner in which the Selected Remedy is implemented will be refined as additional information is developed during remedial design, is likely to differ from the assumptions used in the Final FS, and suggests that the implementation strategy will be flexible and practically based on the relevant information developed post-ROD.

In conclusion, for the above reasons, I deny all relief requested in the June 22, 2016 letters of dispute. In so doing, I specifically determine that the Final FS is compliant with CERCLA and the NCP, and provides an appropriate basis for selecting a remedy in a ROD for the Portland Harbor Site.

Sincerely,

Sheryl Billbrey, Director  
Office of Environmental Cleanup

Enclosure  
Appendix A: EPA's Response to Dispute Issues

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

I. INTRODUCTION

On September 28, 2001, ten parties entered into an Administrative Settlement and Order on Consent to perform the remedial investigation and feasibility study for the Portland Harbor Superfund Site (hereinafter referred to as the “RI/FS AOC”). [AR Doc # 711519] The Respondents to the RI/FS AOC call themselves the Lower Willamette Group (“LWG”). Section XVIII. of the RI/FS AOC provides a dispute resolution process for any disputes concerning “activities or deliverables required under the order.” On February 4, 2016, EPA and the LWG mutually agreed that it would be more effective and efficient if EPA finalized the Feasibility Study. [AR Doc # 100003435] EPA and the LWG also agreed that the LWG could dispute the final FS within 14 days of publication of the final FS along with the Proposed Plan. Specifically, the February 4 letter [Page 2] agreement stated:

The EPA will allow the LWG AOC signatories to dispute the final FS that the EPA produces and publishes along with the Proposed Plan. In making this agreement, if any LWG AOC signatories decide to dispute the final FS under Section XVIII of the AOC, the LWG signatories must submit their Dispute Statement within 14 days of the publication of the Proposed Plan. The Dispute Process under the AOC would be streamlined by proceeding directly to the formal determination phase wherein the Director’s decision is anticipated to be made simultaneously with the agency’s remedy decision after considering all public comments along with the disputed issues. In accepting this agreement, the LWG agrees that, because the dispute process will be conducted during the public comment period, the LWG’s Dispute Statement will be placed in the administrative record and the dispute process will be conducted consistent with requirements for public participation for the proposed remedy decisions under CERCLA the NCP, and federal law.

Section XII., Paragraph 1 of the AOC [Page 22] provides that EPA retains responsibility for preparation and release of the Proposed Plan and Record of Decision. The FS is a separate and distinct document from the Proposed Plan. Likewise, under the terms of the AOC, the Proposed Plan was not an “activity or deliverable” that the LWG was required to produce. Therefore, the scope of this dispute is limited to issues concerning the June 2016 FS [AR Doc # 840000 through 840019], not the Proposed Plan. Additionally, consistent with the agreements reached in the February 4 letter, EPA’s disapproval of the LWG’s 2012 FS also is not within the scope of this dispute.

Moreover, throughout the LWG’s dispute statement, they ask for an explanation or rationale for why EPA’s final FS was changed from an earlier draft FS, hereinafter the August 2015 FS. As stated above, the subject of the dispute process is only EPA’s final FS, so the responses below focus on the particular issues raised with the final FS and we do not explain every change made from earlier drafts unless needed to fully respond to a specific final FS issue.

EPA published the Proposed Plan and FS, along with the administrative record, on June 8, 2016. On June 22, 2016, seven out of the ten AOC signatories submitted three separate

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Dispute Statements.<sup>1</sup> [AR Doc # 100031247, 100031251, 100031255, 100031259, 100031265, 100031266, 100031275, 100031277, 100031278] The collective group of seven submitted a Dispute Statement, in which Arkema, Evraz, Gunderson, NW Natural, TOC Holdings, Inc. and Union Pacific attached additional issues in an Appendix to their dispute statement. LSS, Inc. (agent for Arkema, Inc.) and Union Pacific submitted separate Dispute Statements as well. Below are EPA's responses to all three Dispute Statements. We have organized the responses by each Dispute Statement, i.e., LWG Response, Arkema Response and Union Pacific Railroad Response. However, if an issue was already raised and discussed, EPA provides a reference to where the discussion is provided.

The LWG, including each individual Respondent to the RI/FS AOC, has had significant input and opportunities to comment on EPA's FS for the Portland Harbor Site. EPA began discussing its ideas and proposals for modifications to the LWG's 2012 draft FS since at least December 2012 when EPA notified the LWG that it could not approve the LWG's 2012 draft FS. [AR Doc # 100007299] EPA shared and discussed its draft modifications on FS Section 1 starting on July 8, 2014, and made changes based on the LWG's requested modifications and issues to that Section. [AR Doc # 100009736, 100010079, 100010083, 100010101, 100010298, 100010490, 100010848, 100010854, 100010876, 100011126, 500003669, 100015709] Likewise EPA provided and discussed modifications to Section 2 on February 23, 2015 and made changes to that chapter as a result of the LWG's requested modifications and issues to that Section. [AR Doc # 100013186, 100015799, 100015924, 100015925, 100013288, 100017731, 100015709] Sections 3 and 4 of the draft modified FS were shared on July 29 and August 18 2015, respectively, and the LWG had the opportunity and provided significant comments on those last two sections to Region 10. [AR Doc # 100017731, 100003852, 100016145, 100015709, 100003806] The LWG also had the opportunity to provide recommendations for the proposed remedy to the National Remedy Review Board and Contaminated Sediment Technical Advisory Group in which they also provided their comments on the draft modified FS. [AR Doc # 1412910] Over all of this time, EPA and LWG had meetings at both the technical staff level and senior management levels regarding the direction EPA was going in its modifications to the FS. Every step of the way, EPA considered the LWG's comments in producing the 2016 FS. EPA has been transparent and open with the direction and scope of the modifications that it determined was needed to the LWG's 2012 draft FS. The LWG has had significant opportunities to raise comments and issues. In addition to this dispute opportunity, the LWG collectively or as individual commenters had the opportunity and have taken advantage of their rights to submit public comments on the Proposed Plan and administrative record through the public participation process and comment period on the Proposed Plan.

After considering all of the Dispute Statements and responses, the fundamental conclusion is that EPA's 2016 FS contained appropriate remedial alternatives that were

---

<sup>1</sup> The seven LWG members are: Arkema, Inc., Chevron, U.S.A. Inc., Evraz, Inc. N.A., Gunderson LLC, NW Natural, TOC Holdings Co. and Union Pacific Railroad Company.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

evaluated consistent with the NCP and EPA guidance. The development and evaluation of the alternatives adequately reflected the scope and complexity of the remedial action and site problems being addressed. Some minor textual or technical errors or omissions were found while responding to some of the dispute issues or other public comments many of which have been corrected in response to comments; however, none of the errors or omissions were fundamental nor undermine the basis for the final remedy decision documented in the Record of Decision. The 2016 FS as supplemented by this Responsiveness Summary and all of the corrections, clarifications, and supplemental analysis contained herein along with remainder of the administrative record support the selected remedy documented in the Record of Decision.

## **II. LWG DISPUTE STATEMENT RESPONSE**

The LWG's dispute statement objected to EPA's modifications to the LWG 2012 draft FS and stated three bases for their objections to the 2016 FS, which are summarized below:

1. EPA's conclusions that alternatives B and D are not protective or fail to comply with ARARs is based upon methods that are inconsistent with the remedial investigation and baseline risk assessments. EPA's failure in the June 2016 FS to evaluate protectiveness in a manner consistent with the approved risk assessments and with sound risk management principles results in large areas being designated for active cleanup where risks are either not present or cannot be meaningfully reduced through a sediment cleanup.
2. EPA's June 2016 FS lacks a complete and transparent evaluation of the long- and short-term effectiveness and cost-effectiveness of its alternatives, as well as the degree to which those alternatives reduce the toxicity, mobility or volume of hazardous substances, including PTW, through treatment. EPA's 2016 FS also: (1) has inadequate cost estimates; and (2) does not have an evaluation of how long it will take each alternative to achieve cleanup levels. Therefore, a proper analysis of alternatives would not result in selection of Alternative I.
3. EPA's FS fails to articulate a framework and schedule for implementation by which each alternative can be compared. EPA's 2016 FS should describe what adjustments to the selected cleanup are possible or how adjustments would be determined. EPA should identify in its alternatives development and decision trees what refinements can be made through remedial design and implementation.

The LWG raised numerous issues in support of one or more of their objections; some of which were very general and others more specific. Responses to their issues are provided below, and demonstrate that EPA's 2016 FS appropriately evaluated protectiveness in a manner consistent with the NCP, including appropriately applying the conclusions from both the Baseline Human Health Risk Assessment ("BHHRA") [AR Doc # 713364] and Baseline Ecological Risk Assessment ("BERA") [AR Doc # 1432515 and 1432516], where appropriate. Likewise, EPA's 2016 FS complies with the NCP and is transparent about the long and short-term effectiveness of each alternative as well as how all of the

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

other seven NCP criteria were evaluated. Lastly, neither the NCP nor EPA guidance requires a FS to provide a framework and schedule for implementing each alternative, nor to describe what adjustments are possible in implementation. EPA's 2016 FS did, however, identify throughout the report various information, data and analysis that would be needed for remedial design.

The following provides each issue in italic text as discussed in detail in the dispute document, including footnotes and references when they added further technical support for dispute issue, and follows with EPA's position on each of the disputed issues in regular text. Since these three issues raised by LWG had many parts, EPA has provided numbering to allow reference between issues raised by the LWG and by individual LWG parties that have submitted dispute statements.

**LWG Dispute Issue 1**

*EPA's conclusions that certain alternatives are not protective or fail to comply with ARARs are based upon evaluations that are inconsistent with the approved remedial investigation and baseline risk assessments and fail to apply appropriate risk management principles.*

**LWG Dispute Issue 1a:**

*EPA has not explained why Alternatives B and D are not protective of the environment. EPA believes that all alternatives (except the "no action" alternative) are protective of human health. However, contrary to its August 2015 FS, EPA has now identified Alternatives B and D as not or possibly not protective of the environment.<sup>9</sup> As best we can tell, EPA has changed its conclusion about Alternatives B and D based largely on its revised approach to benthic risk.<sup>10</sup>*

*<sup>9</sup> In part, EPA bases its determination that Alternative B and D may not be protective of ecological risk on the fact that institutional controls do not effectively prevent exposure by ecological receptors. However, all alternatives rely to some extent on institutional controls, and this was also the case with all alternatives in the August 2015 FS.*

*<sup>10</sup> The LWG has previously commented that EPA should use the Comprehensive Benthic Risk Areas (CBRA) approach previously developed based upon the approved BERA to evaluate benthic risks consistent, and the NRRB commented that EPA should revisit the benthic approach for the final FS. National Remedy Review Board and Contaminated Sediments Technical Advisory Group Recommendations for the Portland Harbor Superfund Site (EPA, December 31, 2015), p. 4.*

**EPA Position:**

The evaluation of overall protection of human health and the environment for Alternatives B and D is discussed in Sections 4.2.2.1 and 4.2.3.1 of the 2016 FS. EPA concluded that these alternatives were protective of human health because institutional controls can be set in place to ensure protection until such time as cleanup levels are achieved. Since institutional controls cannot be placed to ensure protection of the environment, EPA concluded that these alternatives were unlikely to be protective of the

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

environment. The determination was not made solely based on benthic risk as purported by the Respondents but rather on a more broad-based evaluation consistent with EPA guidance as discussed in more detail below. As stated in Sections 4.2.2.1 and 4.2.3.1 of the 2016 FS, the determination of protectiveness is drawn from the evaluation of all the RAOs and the uncertainty analysis presented in Appendix I. Protection of the environment draws from RAOs 5, 6, 7, 8 and 9: RAO 6 had post-construction HQ of 34 for BEHP.

Based on recommendations from the NRRB/CSTAG (see NRRB/CSTAG comment on Remedy Performance, p. 5), EPA performed an uncertainty analysis of each alternative to determine the likelihood that the Alternative would significantly differ from the No Action alternative. This analysis was presented in Appendix I of the 2016 FS, and the conclusion was that Alternative B post-construction SWACs were statistically indistinguishable from the No Action alternative and that the post-construction SWACs for Alternative D were still within the margin of error relative to no action. Since the No Action alternative was deemed to not be protective, EPA reasons that Alternatives B and D are also not protective since Alternative B was statistically indistinguishable from the No Action alternative, and Alternative D was only slightly better for PAHs and PCBs (the SWAC from the DDx RAL for Alternative D were also statistically indistinguishable from the No Action alternative).

As stated in EPA's RI/FS Guidance (USEPA 1988), "The overall assessment of protection draws on the assessments conducted under other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs." EPA's assessment was that an insufficient amount of active remedy was conducted under these alternatives to ensure that the environment would be protected in a reasonable time frame, if at all (see discussion of long-term and short-term effectiveness in Sections 4.2.2.3, 4.2.2.5, 4.2.3.3, and 4.2.3.5 of the 2016 FS).

With regard to footnote 10, the Comprehensive Benthic Risk Approach (CBRA) developed by the LWG on their own initiative provided in the LWG's 2012 FS (Appendix P); it was not done as part of or consistent with the BERA as stated by the Respondents. EPA disapproved the LWG's 2012 FS, including the CBRA, in a letter dated December 18, 2012. [AR Doc # 100007297, 100007298, 100007299] Comment 1 attached to EPA's disapproval notice noted that the benthic risk evaluation provided in the LWG's 2012 FS would need outstanding issues to be resolved. EPA had started working with the LWG to resolve outstanding issues, but found that the approach was inconsistent with CERCLA, the NCP, and EPA policy and guidance in that it was based on bioassays and models which were not linked to hazardous substances released at the Site. The NRRB/CSTAG recommended that EPA's PRGs for benthic risk be consistent with the benthic SQVs in the BERA (See NRRB/CSTAG comments on Human Health and Ecological Risk, AR Doc # 100001536), but were silent on the approach to use to evaluate benthic risk as purported by Respondents.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

**LWG Dispute Issue 1b:**

*EPA made extensive changes to the benthic approach for this FS, but those changes are still inconsistent with the comprehensive benthic risk approach contained in the approved Baseline Ecological Risk Assessment (BERA). The FS states: “The protection of benthic species to [sic] contaminated sediment is evaluated using the benthic risk area defined by an order of magnitude greater than the RAO 5 PRGs. The post-construction interim target for RAO 5 was established at 50 percent reduction in the area posing unacceptable benthic risk.” So, instead of using the Comprehensive Benthic Risk Area (CBRA) approach previously developed collaboratively with EPA and the LWG using multiple lines of evidence, EPA now maps benthic PRG exceedance factors on a point-by-point basis and uses a 10 times exceedance factor to identify areas of concern. EPA then concludes that if 50% of this area is actively remediated, the alternative is “protective” on an interim basis. It is completely unclear how this new method is: 1) in any way more accurate or consistent with the BERA; and 2) more predictive of benthic risk or the effectiveness of the alternatives, as compared to simply using the previously developed CBRA, which are entirely consistent with the BERA.<sup>12</sup>*

*12 Further, benthic risk models do not honor the measured data. Although the LRM and FPM are model predictions using data from the toxicity tests conducted with site sediments, some of measured data is not honored. Any modeled risk for benthic invertebrates that ignores actual toxicity testing results needs to be assessed in weight-of-evidence and river-mile specific decision-making. The benthic risk footprints should not extend into areas shown to have a lack of toxicity based on actual laboratory toxicity tests. Though EPA states measured toxicity data were reviewed to evaluate correlation with model predictions (EPA June 2016 FS Appendix D, p D-31), the resulting areas are not consistent with the BERA.*

**EPA Position:**

See EPA’s position to LWG’s dispute issue 1a regarding the CBRA. The LWG’s dispute statement does not provide a clear or specific basis for why the CBRA should be used instead of the BERA and the 2016 FS alternatives evaluation approach. The rationale for the approach used in the 2016 FS is explained below.

In the BERA, impairments in survival and growth (expressed as biomass) were directly measured at nearly 300 locations in site-specific sediment toxicity tests with two benthic invertebrate species, approximately 20 percent of the total number of sediment samples collected for chemical analysis. The co-occurring sediment contaminant concentrations in sediments where toxicity was observed were used in the development of two site-specific predictive models of sediment toxicity, the floating percentile model and the logistic regression model. Contaminant concentrations predicted to be toxic from these two models, as well as the empirical data, were used to evaluate benthic risk on a point-by-point basis in the final BERA. The two models are also the source of many of the RAO 5 sediment PRGs for ecological risk. The PRGs for RAO 5 were the SQVs derived in the BERA and are thus consistent with the conclusion of the BERA.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

The comprehensive benthic risk area developed by EPA is shown in Figure 4.1-1 of the 2016 FS and is the cumulative footprint of all RAO 5 PRGs. Mapping of benthic risk areas based on a point-by-point PRG exceedance is justified due to the limited mobility of many of the benthic species. This means that some benthic species are exposed to contaminant concentrations posing unacceptable ecological risks (defined as the RAO 5 PRGs) for their entire lifetime. Additionally, benthic species are likely exposed to sediment contaminant concentrations for a sufficiently long exposure duration that results in contaminant bioaccumulation to concentrations (the RAO 6 PRGs) posing risks to aquatic-dependent wildlife species that prey on benthic species.

Under EPA's Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments – Interim Final (June 1997) adverse effects on populations can be inferred from measures related to impaired survival, reproduction and/or growth. A subsequent EPA Policy memorandum (Issuance of Final Guidance: Ecological Risk Assessment and Risk Management Principles for Superfund Sites, OSWER Directive 9285.7-28 P, October 7, 1999) states that ecological risk assessments are intended to protect local populations and communities of biota. Contaminant concentrations that are expected to protect local populations and communities can be estimated by extrapolating from effects on individuals and groups of individuals using a lines-of-evidence approach. This approach was extensively used to evaluate ecological risks at Portland Harbor. However, the conclusions of the BERA provide for which contaminants are posing unacceptable risk based on those lines-of-evidence (site-specific toxicity tests, bioaccumulation models, and species diversity studies; BERA Table 3-1). These are all based on empirical site data and these lines-of-evidence cannot be used to determine effects to the benthic population through means other than empirical testing post construction.

In the 2016 FS, PRGs are developed for those hazardous substances that are posing unacceptable risk at the Site. EPA adopted the site-specific SQVs from the BERA for RAO 5 consistent with the recommendations of the NRRB/CSTAG. The footprint of each PRG was evaluated against the L2/L3 exceedances from the bioassays and both predictive models to determine if the benthic risk coincided with the release of these contaminants. The maps presenting that information is presented in the 2016 FS, Appendix D11. EPA used best professional judgement to not address all benthic risk through dredging and capping and allow for some benthic risk to be addressed through MNR. However, in conducting the evaluation of alternatives, it is necessary to discuss the overall protectiveness. Since a model is not available to determine if these PRGs will be achieved in a reasonable time frame, EPA used best professional judgement to evaluate overall protectiveness for RAO 5 in the 2016 FS (Section 4.1-3, p.4-8) as:

The protection of benthic species to contaminated sediment is evaluated using the benthic risk area defined by an order of magnitude greater than the RAO 5 PRGs. The post-construction interim target for RAO 5 was established at 50 percent reduction in the area posing unacceptable benthic risk. This is acceptable because protection of the benthic community is based on a population rather than individual effects, and is considered a

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

target to which the benthic population as a whole can be stressed and still recover, in conjunction with the uncertainty associated with the predictive models used to develop these PRGs.

Thus, the 2016 FS used the same metric as all other RAOs in establishing an interim goal that was an order of magnitude greater than the PRGs. EPA's rationale in the 2016 FS that this was reasonable since there is uncertainty based on the conservativeness of the SQVs used in the models (see BERA Section 6.2.5). Since benthic risk is made on a population basis, EPA's best professional judgement was that the entire affected community of benthos did not need to be addressed through capping and dredging and made an assumption that if 50 percent was addressed through active remediation of the highest contaminant concentrations, the other 50 percent would be addressed through MNR for the lower contaminant concentrations. Since benthic effects from contaminated sediment are due to survival, reproduction and growth (not just survival), this approach would also ensure that the entire population was not diminished through active remediation (capping and dredging will affect the survival – or kill - benthic organisms where it occurs) and some of the population affected through reproduction and growth could recover more slowly through MNR.

**LWG Dispute Issue 1c:**

*EPA's conclusion that Alternatives B and D are not protective of the environment may also relate, at least in part, to EPA's decision to evaluate the performance of its alternatives based upon recalculated surface weighted average concentrations (SWACs) rather than those used in its August 2015 FS (used by EPA to estimate post-construction risks, detailed in EPA's Appendix J). The selection of a preferred alternative at a sediment CERCLA site is very sensitive to and dependent (i.e. "sensitively dependent") on the SWAC value of site; however, nothing in the June 2016 FS explains why EPA has changed its methodology for calculating SWACs between the August 2015 FS and the June 2016 FS, why EPA believes its current methodologies are superior to its prior methodologies, or even precisely what its current methodologies are.*

*The June 2016 FS appears to use these new SWACs to estimate pre- and post-construction risks for the alternatives. EPA presents an uncertainty analysis in Appendix I that evaluates different methods for estimating SWACs for pre-construction sediment surfaces. Using PCBs as an example, EPA presents SWAC estimates using four different methodologies that range between 79 and 205 micrograms per kilogram ( $\mu\text{g}/\text{kg}$ ). (The natural neighbor method used for Remedial Action Level (RAL) curves in Section 3 estimates a site-wide SWAC of 92  $\mu\text{g}/\text{kg}$ , which does not match any of the values in Appendix I). It is not clearly explained in the main text, but based on tables presented in Appendix J (see Table J2.3-1a), it appears that EPA uses a high-end site-wide SWAC estimate (208  $\mu\text{g}/\text{kg}$ , which is close to 205  $\mu\text{g}/\text{kg}$  but not the same) to represent current site conditions for RAO 2 (i.e., pre-construction risks; identified as post-construction risks for Alternative A). This results in EPA presenting pre-construction risks that are completely inconsistent with risks identified in the approved BLRAs<sup>13</sup>. The risks estimated for Alternative A (no action) should be the same as baseline risks. EPA also assumes that*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*postconstructed surfaces are “zero” (see ES-14). The net effect of these assumptions is that EPA poses technically unrealistic risk reduction estimates for all the alternatives. At the same time, EPA has not explained its use of the highest available estimate for pre-remediation SWACs and associated risks, which estimates are inconsistent with the BLRAs.*

*13 The site-wide fish consumption risks estimated in the BHHRA (summarized in Section 1.2.5.1) are higher than those presented for Alternative A in Table J2.3-1a. However, the risks for Alternative A appear to be based on some estimate of an arithmetic mean concentrations whereas the BHHRA risks are based on 95% UCL or maximum concentrations. The average PCB concentration in the BHHRA based on actual tissue data was 160 ug/kg in bass and 2,500 ug/kg in carp, which includes a single outlier sample of 19,000 ug/kg (the average without the outlier is 353 ug/kg). The modeled tissue concentrations used for Alternative A are 352 ug/kg for bass and 820 ug/kg for carp, which are approximately 2 times higher than the measured tissue concentrations (excluding the single carp outlier). The river mile risks for Alternative A cannot be compared directly with the BHHRA because the risks for Alternative A are calculated based on one-third transects of a rolling river mile (both sides of the river and navigation channel) whereas the BHHRA risks were for an entire (bank-to-bank river mile). However, the risks for Alternative A are generally higher than those in the BHHRA (potentially due to spatial scale issues). In the BHHRA, risks at RM 11 were  $1 \times 10^{-3}$  and all other risks were less than  $1 \times 10^{-3}$ . For Alternative A, EPA’s FS indicates there are several segments with risks of  $1 \times 10^{-3}$  or higher.*

**EPA Position:**

The 2015 draft FS and the 2016 FS both calculated SWACs on an SDU scale in the same manner. The 2015 draft FS did not calculate Site-wide SWACs; this was added to the 2016 FS in order to evaluate protectiveness to the RME based on Site-wide exposure consistent with the BHHRA. The Site-wide SWAC was developed consistent with the exposure of smaller range fish species rather than the methodology used by the LWG in their 2012 draft FS. Thus, EPA did not replace the evaluation, but supplemented it with additional analysis.

EPA evaluated the uncertainty associated with the calculated post-construction SWAC for each alternative as requested in the NRRB/CSTAG comments. The rationale for calculating Site-wide SWACs using alternative methodologies to reduce the bias introduced utilizing a non-random sample is explained in Appendix I of the 2016 FS. EPA is unclear to what Respondents’ definition of “the SWAC value of site” is referring, as a SWAC is merely a spatially weighted concentration. As presented in Section 4.1.1 of the 2016 FS, the comparative analysis of the various alternatives is evaluated on several relevant spatial scales, including Site-wide and on a river mile, or SDU scale.

The 2016 FS, Appendix I, Section I.4, recommends that “with biased sampling prevalent at Portland Harbor it is necessary to spatially weight the data in order reduce bias in the estimated mean and to properly characterize uncertainty bounds.” Therefore, as described

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

in Section J2.1 of the 2016 FS, SWACs were calculated for each of the 27 geographic areas based on the recommendations in Appendix I and the 95 percent upper confidence limit on the mean was calculated for each RAO 2 COC. These UCLs were used as inputs to the FWM to calculate Site-wide average tissue concentration consistent with the final BHHRA. [Appendix I has been updated to include Figure I-9 depicting the 27 geographic areas where the SWACs were calculated for this analysis.] The pre- and post-construction concentrations were then used as the input into the food web model to estimate exposure concentrations to calculate pre-and post-construction risks, consistent with the process used in the BHHRA (the BHHRA calculated the 95 percent upper confidence limit on the mean of concentrations in fish tissue). Use of the food web model to estimate post-construction tissue concentrations is consistent with the process the LWG used in its 2012 draft FS. It is also appropriate to use for estimating risks for the no-action alternative, as the same metric is then used for the comparative analysis. Using the LWG-calculated “site-wide” SWAC of 92 µg/kg for PCBs results in an estimated average tissue concentration of 232 µg/kg, which equates to an estimated risk of  $5 \times 10^{-4}$  from PCBs alone, which is not consistent with and much lower than the  $1 \times 10^{-2}$  risk estimate for PCBs presented in Table 5-74 of the BHHRA. Since the efficacy of each alternative can only be evaluated through the use of predictive tools, and since the results of the BHHRA can’t be replicated through use of the LWG-developed tools, comparing the baseline risks presented in the BHHRA to those estimated by the models would show an unrealistic decrease between the no action alternative and Alternative B.

Due to the lack of a defensible sediment transport model for the lower Willamette River, it was not possible to predict COC concentrations in remediated areas beyond t=0 with any degree of confidence. Assuming a clean residual or cap layer is sufficient for FS purposes and allows for use of a consistent metric of potential risk reduction in the comparative analysis of alternatives.

All risk-based PRGs presented in the 2016 FS utilize the exposure assumptions presented in the EPA-approved baseline risk assessments that are a part of the final RI report. Nonetheless, EPA is perplexed by the LWG’s current concern that the 2016 FS might be “inconsistent with the approved baseline risk assessments,” given that in their 2012 draft FS they abandoned the exposure assumptions from the risk assessments when developing remedial goals, and at that time they were totally comfortable using alternate assumptions. As stated in the 2012 FS (Appendix E, Section 1.1):

“...alternate scientifically valid assumptions from those required by EPA could have been used in the BHHRA and in the development of remediation goals (RGs) for protection of human health.”

**LWG Dispute Issue 1d:**

*EPA’s June 2016 FS improperly aggregates sediment data from 1997 through 2011 for the surface sediment characterization and is therefore significantly inaccurate. If EPA assumes a higher prerediation SWAC value that is inconsistent with the risk assessments and based on outdated data, then more aggressive clean up alternatives may*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*plot closer to the inflection (i.e. “knee”) of the utility curve. That inappropriate portrayal could lead a decision maker to select a remedy that requires more active remediation than is required to achieve cleanup goals. EPA’s use of a SWAC that is inconsistent with the risk assessments exaggerates the benefits of the larger alternatives and artificially drives remedy selection toward larger alternatives (e.g. E, F and I). If the SWAC value is set consistent with the approved risk assessments, the utility curve actually supports remedy selection toward Alternatives B, C and D.*

**EPA’s Position:**

The EPA 2016 FS uses the same “aggregated data” that the LWG used in their 2012 draft FS, except that data from the NW Natural and LSS early actions were also included. The LWG’s 2012 draft FS, Appendix Ha (pp 26-27) states: "Because somewhat limited data were collected at the beginning of the model simulation period, and because the sediment data from that time did not fully characterize sediment levels uniformly throughout the site, the entire FS sediment dataset, which includes sediment data collected between 1997 and 2010 has been deemed representative of current conditions in the site." Further, p.46 of the LWG's 2012 draft FS, Appendix Ha states that “assessment of temporal changes in these data is difficult because this was not and objective of the historical sediment sampling programs ... and as such, sediment data were generally examined qualitatively during model calibration.” Consequently, if aggregating the data was significantly inaccurate or fatally flawed, so was the LWG’s 2012 FS, which they claim incorporated “good science” and “provides an adequate basis for selecting a remedy.” Further, the data collected for the Site was the same data used in the baseline risk assessment and therefore is appropriate to use to determine the expected risk reduction from implementation of each of the alternatives developed in the 2016 FS.

The baseline risk assessments use actual fish tissue data, not sediment SWACs, to determine risk. SWACs are a tool developed for the 2016 FS to compare alternatives to the No Action alternative and are not used nor discussed anywhere in the BERA or BHHRA. In the BHHRA, direct contact exposures to sediment were evaluated by aggregating data by exposure areas and calculating the 95 percent UCL on the mean; sediment data was not used to assess the fish consumption pathway. In the BERA, sediment data was also used to calculate a UCL on the mean of data within various spatial scales of receptors, rather than SWACs. The spatial scales used in the EPA’s 2016 FS are consistent with those used in the risk assessments and the exposure assumptions are the same.

The RAL curves used to develop the remedial alternatives are not risk-based, although it is presumed that reductions in sediment concentrations will subsequently reduce risk since the exposure to contamination would be reduced by reducing the SWAC. The EPA RALs for PCBs, PAHs, and PeCDF are the same as the LWG's RALs for these contaminants in their 2012 FS and the curves are nearly identical (see Figures 3.4-1, 3.4-2, and 3.4-5, Tables 3.4-1, 3.4-2, and 3.4-3, and Appendix D5 of 2016 FS and Figures 4.3-1, Figure in Appendix Db p.89 of pdf, and Table 4.4-1 of the LWG's 2012 draft FS). The placement of the RALs on the curve are irrelevant to the selection of a remedy. How

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

the alternatives perform based on the nine criteria specified in the NCP are the basis of remedy selection.

*The FS fails to explain how the alternatives it has developed contribute to meaningful risk reduction in specific areas of the site. Protectiveness is a threshold criterion under CERCLA, but “protectiveness” does not support an EPA requirement for remedial action in the absence of identified unacceptable risk or failure to comply with an ARAR.<sup>14</sup> The LWG has previously commented that EPA’s August 2015 FS failed to follow the BLRAs or provide a clear description of risk management decisions, resulting in an FS that was inconsistent with the BLRAs in many respects. Many of those comments remain relevant to the June 2016 FS and, in general, we will not repeat them here.<sup>15</sup> However, several aspects of the June 2016 FS contain new or revised evaluations from the August 2015 draft that not only diverge without explanation from the approved risk assessments but lack any demonstration of their superiority to the analyses of the same and similar issues in EPA’s August 2015 FS.<sup>16</sup>*

**EPA Position:**

The phrase “meaningful risk reduction” in the LWG’s dispute is a subjective term and is nowhere defined in CERCLA, the NCP, EPA guidance or policy, nor by the LWG themselves. A discussion of risk reduction is provided in both the overall protection to human health and the environment and the long-term effectiveness discussions of each alternative in the 2016 FS. The discussion of long-term effectiveness discusses post construction risk for each alternative and compares it to the residual risk posed by the PRGs. The interim goals established in Section 4.1.3 of the 2016 FS were based on uncertainty in the PRGs and is used as a point at which EPA believes is acceptable risk for MNR to achieve PRGs in a reasonable time frame.

The 2016 FS is based on the baseline risk assessments and is consistent with the conclusions of those risk assessments. The 2016 FS is also consistent with the NCP and EPA guidance regarding development of PRGs for the Site.

*Issue 17: 17. Risk Inconsistency – EPA’s methods and results are often inconsistent with the BLRAs throughout the FS including Sections 2, 3, 4. This culminates in Section 4 with a residual risk assessment that departs significantly from the methods and findings of the BLRAs. The LWG has commented to EPA on numerous occasions (e.g., LWG 2014d, 2015a, 2015b) that EPA should include risk management steps in the FS consistent with guidance. These comments include that EPA should address only those potential risks for contaminants, media, and pathways that were clearly found to pose unacceptable risks in the BLRAs and that EPA should further focus on the subset of unacceptable risks that are required for selecting an effective and protective remedy using all of the FS criteria. Instead, EPA has departed from the BLRAs and applied virtually none of the risk management steps noted in guidance such as the 2005 sediment remediation guidance and EPA’s 11 Risk Management Principles Memorandum for, “making scientifically sound and nationally consistent risk management decisions at contaminated sediment sites.” The relevance of this guidance to risk management steps in the FS is reviewed in*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*detail in Sections 10.1 and 10.2 of the 2012 draft FS. In summary, EPA guidance (2005a) discusses “Risk Management Principles and Remedial Approaches” and clearly describes that the cleanup should use a “risk-based framework”; “select site-specific, project-specific, and sediment specific risk management approaches that will achieve risk-based goals”; and “ensure that sediment cleanup levels are clearly tied to risk management goals” (p. 1 – 5).*

*Specific issues related to EPA’s lack of consistency with the BLRAs, residual risk assessments, and lack of risk management include:*

- a. Per the LWG’s 2014 Section 2 comments (LWG 2014d) and consistent with law, EPA guidance, and precedents from other sediment sites as detailed in past comments:*
- i. RAOs, COCs, and PRGs should only be designated for contaminant exposure scenario pairs (ecological or human health receptors and pathways) for which the EPA-approved BLRAs identified potentially unacceptable risk from in-river media (e.g., not potential upland source media, and ARARs should not be used to develop PRGs for non-COCs).*
  - ii. PRGs should be established and applied for these COCs consistent with risk assessment methods (e.g., spatial scales) and only where sufficient technically valid information exists to do so.*
  - iii. The FS should focus on those COCs and PRGs that are technically practicable to achieve and for which acceptable risk levels can be reached through the sediment remedial action alternatives being evaluated in the FS.*
  - iv. COCs and PRGs should only be established if reasonably conservative risk management approaches indicate that a contaminant is significantly contributing to risk and that evaluation of remedial alternatives with respect to a PRG for a particular COC/exposure pathway pairing is required in order to select a protective remedy.*

**EPA Position:**

The Portland Harbor Site, as listed on the National Priorities List (NPL), includes an in-river and an upland portion. The 2016 FS focusses on the in-river portion of the Site and establishes RAOs that are protective for that portion of the Site. This includes protection of media such as surface water, pore water, and biota, in addition to sediments. It is clear that EPA may take a response action not only where there is a release, but where there is the potential threat of a release. 42 USC Section 9604(a). Further, the NCP and EPA guidance clearly state that other factors, such as ARARs, MCLGs and MCLs, and water quality criteria are to be used in developing PRGs and that risk-based levels are to be used where these PRGs are not available or risk cumulatively exceed  $10^{-4}$ . Thus, exceedance of a water quality criterion or an MCLG/MCL can be a basis for action in addition to the findings of a risk assessment.

CERCLA 104(a)(1) states "Whenever (A) any hazardous substance is released or there is a substantial threat of such a release into the environment, or (B) there is a release or substantial threat of release into the environment of any pollutant or contaminant which may present an imminent and substantial danger to the public health or welfare, the President is authorized to act, consistent with the national contingency plan, to remove or arrange for the removal of, and provide for remedial action relating to such hazardous substance, pollutant, or contaminant at any time (including its removal from any

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

contaminated natural resource), or take any other response measure consistent with the national contingency plan which the President deems necessary to protect the public health or welfare or the environment."

42 USC Section 9604(a)(1). The NCP [40 CFR Section 300.430(e)(2)] states that RAOs shall be developed considering (A) ARARs using factors of acceptable risk for systemic toxicants, cancer risks when ARARs not available, detection/quantitation limits, uncertainty, or other pertinent factors, (B) non-zero MCLGs, (C) MCLs, (D) when cumulative risk from ARARs is greater than  $10^{-4}$ , use factors in (A), (E) water quality criteria, (F) ACLs, (G) levels protective of ESA T&E species.

EPA policy *Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions* (OSWER Directive 9355.0-30, USEPA 1991) states that "For sites where the cumulative site risk to an individual based on reasonable maximum exposure for both current and future land use is less than  $10^{-4}$ , action generally is not warranted, but **may be warranted if a chemical specific standard that defines acceptable risk is violated** or unless there are noncarcinogenic effects or an adverse environmental impact that warrants action."

EPA's 1991 policy also states that "Where the **cumulative carcinogenic site risk** to an individual based on **reasonable maximum exposure** for both current and future land use is less than  $10^{-4}$  and the non-carcinogenic hazard quotient is less than 1, action generally is not warranted unless there are adverse environmental impacts." (emphasis added) Both the BHHRA and BERA conclude that there is unacceptable risk at the Site that warrant EPA action (cumulative risk greater than  $10^{-4}$  and HI or HQ greater than 1); thus, action is warranted at this Site.

Neither CERCLA, the NCP, nor EPA policy or guidance states that action may only be taken where risks are identified in the risk assessments. The NCP is clear that action may also be taken based on an exceedance of an MCLG/MCL or water quality criterion. Further, the risk assessments did not evaluate specific exposures in every area of the Site due to lack of data. The upland sources are not separate and distinct from the contamination in the river. The 2016 FS covers the in-river portion of the Site and thus the RAOs and PRGs must be developed to protect the media and pathways for which contamination is present. Since the RAOs and PRGs developed for this Site are based on the baseline risk assessments and ARARs, those areas of the Site which already achieve PRGs would not require action since the PRGs are already attained. EPA provides the basis for the establishment of PRGs for each RAO in Section 2 and Appendix B of the 2016 FS.

*v. Consistent with EPA background guidance (EPA 2002), PRGs should not be set below reasonably achievable anthropogenic background levels (this includes the concept of "equilibrium" as explained in LWG 2014g). The LWG's Section 2 comments (LWG 2014d) detail how each of these concepts is consistent with remediation regulations and guidance.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

**EPA Position:**

See EPA's position to LWG's dispute issue 1r.

*b. Similarly, RALs for each COC should be applied consistent with the exposure and potentially unacceptable risk areas defined for that COC in the BLRAs (e.g., RALs should not be applied where the exposure pathway or unacceptable risks for those COCs do not currently exist). This is consistent with the "risk-based framework" required by guidance, as cited above. The issue of RAL consistency with the BLRAs is also noted in the Comment 3.*

**EPA Position:**

As EPA has stated many times to the LWG, the RALs are not risk-based (with the exception of Alternative H, which uses the PRGs as RALs). The RALs are concentrations of focused COCs only, but are meant to cover all COCs posing risk to various receptors at various spatial scales. Thus, the RALs in combination, not individually, are meant to address all COCs, not just the specific focused COC. The RALs, therefore, apply everywhere within the Site where any PRGs are exceeded. In conducting the evaluation of the alternatives, EPA looked at how each alternative met the PRGs. This was conducted for each RAO and was specific to the COCs, PRGs, and spatial scales relevant to that RAO. Both risk assessments show that PAHs contribute to unacceptable risk at the Site, not just from direct contact, but also as a dietary component.

Further, the EPA guidance does not require, but recommends 11 principles which principle 5 is "Use an iterative approach in a risk-based framework." The 11 principles guidance describes this principle broadly to include approaches that incorporate testing of hypotheses and conclusions and foster re-evaluation as new information is gathered, any early or interim actions planned or implemented at the site that address threats from contaminated sediment, or whether the proposed sediment remedy will be part of a larger phased approach to the site as a whole. EPA discussed how this principle was addressed in the memo sent to the OSRTI Sediment Team on October 22, 2015, which is part of the OSRTI Sediment Team review concurrent with the NRRB review process. [**AR Doc # 100012830**]

As discussed in guidance, this principle is meant to provide an iterative approach as information becomes available. EPA has used this approach throughout the RI/FS process to screen out contaminants not detected in the RI, screen out contaminants not posing risk after completion of the baseline risk assessments, and further screened out some contaminants that were posing potential risk at the Site in the FS based on information presented in the 2016 FS, Table 2.2-2. [See also updated version attached to this dispute.] However, some questions remain and data needs to be collected for other contaminants.

As stated above, EPA will only require action where contaminants exceed PRGs in a particular media. If the PRGs are attained in a particular area of the Site, then action would not be required. The 11 principles are silent as to the use of RALs since these are

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

not a required tool at sediment or other CERCLA Sites. The OSRTI Sediment Team did not provide any comments to the Region that there were deficiencies in the memo.

*c. EPA presents a residual risk evaluation in Section 4 and indicates that the risks were calculated using methods consistent with the BLRAs. No details are provided on how the risk calculations were performed. Appendix H is entitled "Residual Risk Evaluation," but this appendix only contains a brief description of how time-zero SWACs were estimated on a rolling river mile basis. Additional information on the exposure assumptions, exposure point concentrations (for both sediment and tissue), and toxicity values is needed to evaluate consistency with the BLRAs. EPA's statement of consistency with BLRA methods is not enough to ensure that the methods are fully understandable or reproducible. Regardless, even based on the limited information presented, it is clear that EPA's methods are not consistent with the BLRAs in at least several respects. Examples include:*

- i. For human health sediment direct contact, time-zero SWACs were generated for shoreline areas (excluding the navigation channel) on a 1- river mile spatial scale, according to Appendix H. (However, the main text indicates instead that 0.5 river mile spatial scales were used. Also, Figure 4.2-1 suggests that EPA included the navigation channel in RAO 1 assessment, which would be incorrect.) Regardless, of how EPA actually did the assessment, sediment direct contact risks were evaluated in the BHHRA for shoreline half river miles, excluding the navigation channel.*
- ii. For human health fish consumption risks, SWACs were generated on a 1-river mile basis longitudinally split into the two shoreline areas and the navigation channel. However, in the BHHRA risks were evaluated by whole river miles with no longitudinal splitting for recreational fish consumption. Further, it is unclear which fish consumption scenario is actually being presented in the residual risk figures. If the subsistence fisher scenario is being presented, this was evaluated on a Site-wide basis in the BHHRA (not by river mile). The text on page 4-6 indicates that EPA calculated tissue concentrations from the SWAC estimates, but no tissue concentrations are presented. The text also indicates that these estimated tissue concentrations were compared to the PRGs for RAO 2. The LWG indicated in the Section 2 comments (LWG 2014b, 2015a, 2015b) disagreement with several aspects of EPA's tissue PRG calculations (and that such tissue levels should be classified as PRGs at all) because EPA was not consistent with the BHHRA methods.*
- iii. The human health residual risks for Alternative A are higher than the maximum risks calculated in the BHHRA, which indicates there are inconsistencies (residual risks should not be higher than baseline). The highest non-cancer risk for a breastfeeding infant in the BHHRA was 10,000. The residual risk assessment indicates the highest non-cancer risk for a breastfeeding infant would be 210,000.*
- iv. There is a significant disconnect between the BHHRA and residual risks for RAO 2 for dioxins/furans. For a breastfeeding infant, the highest hazard quotients for dioxin/furan TEQ calculated in the BHHRA were 10 on a Site-wide basis (tribal fish consumption, whole body diet) and 10 on a river-mile basis (recreational RME consumption, RM 7). Figure 4.2- 4c(1) indicates that the HQ from HxCDF alone (not the entire TEQ) is more than 14,000 for Alternative A. For a child, the highest hazard quotients for dioxin/furan*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*TEQ calculated in the BHHRA were also 10 on a Site-wide basis (tribal fish consumption, whole body diet) and 10 on a river-mile basis (recreational RME consumption, RM 7). Figure 4.2- 3f(1) shows a HQ greater than 30 for just HxCDF. The RfD has changed since the BHHRA was completed, but that does not account for the difference between the BHHRA and residual risks.*

**EPA Position:**

EPA's residual risk evaluation is discussed in Appendix J of the 2016 FS. The approach used is consistent with the baseline risk assessments. RAO 1 was evaluated in shoreline areas only, not in the navigation channel, and evaluated on a half-river mile scale, which is consistent with the exposures in the BHHRA. RAO 2 was evaluated on both a Site-wide scale using PRGs based on a consumption rate of 142 g/day and one-river mile (including SDU) scale using PRGs based on a consumption rate of 49 g/day. While the exposure assumptions for RAO 2 are consistent with the risk assessment, EPA agrees that in the BHHRA risk was evaluated to the recreational fisher averaging tissue data across the river and the post-construction risk evaluated in the 2016 FS was on a river mile scale in river mile zones (east, navigation channel, west, and Swan Island Lagoon).

It is not uncommon and is acceptable to aggregate the data differently than evaluated in the baseline risk assessment in order to conduct a feasibility study that is evaluating the effect of cleanup of contamination in the river. The river mile data for the risk assessment were collected based on the home range of certain fish species, not the fishing pattern of the receptor. The risk assessment used river mile data for smallmouth bass composited across the river based on Round 1 data collected in 2002-2004. In 2005, ODFW conducted a radio tracking survey of several species and found that smallmouth bass are most commonly found in nearshore areas within a 1 km range of where they were released (ODFW 2005). Future sampling was then conducted for individual fish on either side of the river, but was aggregated in the same manner as the Round 1 data so that the data would still be comparable. Further, only smallmouth bass was used to assess risk on a river mile scale since other fish species were composited over a minimum of three miles. The 2016 FS calculated residual risk for all four fish species evaluated in the BHHRA based on a one river mile scale in the nearshore zone consistent with the preferred fish habitat and the assumptions of "recreational" fishers evaluated in the BHHRA. The calculated tissue concentrations are provided in Appendix J Table J1-2.

The 2016 FS was not attempting to replicate the BHHRA. There will be differences in the risks based on the methodology and data used. The BHHRA used fish data to assess the risk for RAO 2. The 2016 FS is using sediment data to predict a fish tissue concentration using the FWM and does not account for contaminant concentrations in water since the focus of the cleanup is the contamination in the sediment. Further, not all contaminants posing risk in this pathway were used in the residual risk assessment due to the inability to correlate sediment concentrations with tissue concentrations for some contaminants. The non-cancer risk for a breastfeeding infant of 10,000 in the BHHRA is on a Site-wide scale. The 2016 FS calculates that this risk would be 3,333. The non-cancer risk for a breastfeeding infant calculated in the 2016 FS only shows risk for this pathway greater

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

than 10,000 at RM 7W for HxCDF, where the maximum risk is 253,347 (see Table J2.3-5c). The BHHRA showed risks for this pathway at RM 7 was 200 based predominantly on PCBs (Table 5-108). The disparity in these values is due to the aggregation of the data. As stated above, the fish data were averaged across the river and only included one of the four species used to assess risk in the risk assessment. Further, the risk assessment only uses smallmouth bass data to calculate risk on a river mile scale and the lack of data for lower trophic level fish which have higher tissue concentrations underestimates the risk and is acknowledged in the uncertainty section of the BHHRA (Section 6.1.1.10). The 2016 FS used the FWM, which allows evaluation of risk from consumption of all four species; thus, the calculated risks would not be directly comparable to the BHHRA. The 2016 FS also uses average sediment concentrations in river zones calculated on a one-river mile scale. The assumption then is that the fish are exposed to that concentration. Therefore, the analysis in the 2016 FS is based upon the representativeness of the data.

*v. Continued exclusion of the site use factor from the BHHRA for BaPEq RAO 1 PRG (106 µg/kg) results in concluding that not even Alternative G will result in SWACs meeting the PRG at time zero in east and west river miles (per EPA's Table 4.2-1). However, if the BHHRA site use factor is accurately applied to this PRG (424 µg/kg), Alternative A appears to achieve RAO 1 in all East RMs (according to EPA's Figure 4.2-7b).*

**EPA Position:**

A factor of 25 percent (which corresponds to a site use factor of 4) was used for direct contact to sediment in the BHHRA to account for the time spent fishing in any single area within the Site. Therefore, the total risk to the fisher is based on any four areas of the Site. Thus, the maximum direct contact risk to the fisher from the BHHRA is  $1 \times 10^{-4}$  and  $HI=3$ . The PRGs developed in the 2016 FS are meant to be applied Site-wide and are established at a  $1 \times 10^{-6}$  risk level or  $HI=1$ , consistent with the NCP and ARARs. While the application of site-use factor may be appropriate assess the risk within a specific area, PRGs are intended to be applied uniformly to each area because actual activity patterns are not known. When potential exposure at more than a single area is considered likely, use of a site-use factor is no longer protective. Further, applying the use factor as suggested by the Respondent would still result in areas in the east river miles exceeding PRGs (see 2016 FS Table J2.2-1c).

*vi. Residual risk figures should show and Section 4 should discuss human health risks compared to a  $10^{-4}$  threshold in addition to the  $10^{-6}$  threshold to fully evaluate the range of effectiveness. EPA's Section 2 presents PRGs calculated on both a  $10^{-4}$  and  $10^{-6}$  thresholds. EPA should evaluate alternatives in the entire acceptable risk range ( $10^{-4}$  to  $10^{-6}$ ) against the FS evaluation, not just variations of RALs all targeted at  $10^{-6}$  or lower risk.*

**EPA Position:**

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Residual risk is defined as the risk remaining once PRGs are achieved. Therefore, residual risk is calculated as the cumulative risk based on the selected PRGs. PRGs are calculated assuming a  $1 \times 10^{-6}$  risk or HQ of 1 and ARARs consistent with the NCP. The exceptions are where background concentration (based on EPA guidance on background) or analytical quantitation limits (per NCP) are greater than the risk-based PRGs or ARARs are not sufficiently protective. As discussed above, RALs are not established at risk levels but are established at levels greater than the PRGs. The 2016 FS does discuss the ability of each of the alternatives to achieve the  $10^{-4}$  carcinogenic risk level as an interim target post construction to ensure that even if PRGs are not achieved, the residual risk is within EPA's acceptable risk range.

*vii. For ecological sediment direct contact, SWACs were generated on a 0.2-mile basis with longitudinal splitting. This spatial scale may or may not be representative of the combined lines of evidence approach used in the BERA to assess benthic risks, given areas of benthic risk were defined for various sized clusters of sampling stations. Further, the hazard quotients presented in the figures appear to be generated by simply dividing the SWAC by the individual PRGs in Section 2, which are mostly based on generic literature Probable Effects Concentrations (PECs). The LWG has already commented on Section 2 (LWG 2014b, 2015a, 2015b) that use of the individual PECs is not consistent with the BERA determinations of benthic risks using multiple lines of evidence.*

**EPA Position:**

The purpose of the FS is to evaluate cleanup options, not establish risk. The BERA used several lines of evidence to evaluate risks to benthic receptors present at the site and concluded that contamination posed unacceptable risk. Therefore, cleanup goals are developed to ensure that the identified risks at the Site are addressed. The evaluation of residual risk is based on the risks remaining once PRGs are achieved. In the 2016 FS, RAO 5 was changed from direct contact to benthic risk. The COCs are based on the BERA recommendation to base the remedy on the ecologically significant COCs (see Section 11 of the BERA). The PRGs for this RAO were based on the BERA SQVs as recommended by the NRRB/CSTAG. The PRGs are mapped in the 2016 FS against the benthic stations to ensure that the contaminant was contributing to benthic risk and then aggregated to compose the comprehensive benthic risk area (see 2016 FS, Appendix D11).

*viii. For ecological bioaccumulation risks, SWACs were generated on a 1-river mile basis with longitudinal splitting. However, the receptors that appear to be used in the residual risk calculations were evaluated over various exposure spatial scales. For example, osprey egg assessment appears to be the receptor of choice for dioxin/furans and DDE, and osprey exposure was assessed in the BERA on a much larger spatial scale than 1 river mile. Thus, it is unclear how EPA's one spatial scale assessment can be consistent with all of these various BERA assessments. Further, the LWG has already commented for Section 2 that some of the receptors EPA focuses on for RAO 6 PRG development, and EPA presumably is focusing on for this residual risk assessment, are*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*inappropriate and inconsistent with the BERA for reasons detailed in those past comments (LWG 2014b, 2015a, 2015b).*

*ix. The statement in Section 4.1.6.1 that “ecological hazard quotients are calculated using the estimated sediment concentrations and the riskbased PRGs for RAOs 5 and 6, consistent with the process used in the BERA” is misleading in its claim that RAO 5 and 6 PRGs are risk-based. The assertion that this EPA process used to calculate ecological hazard quotients is consistent with the BERA is obviously wrong because ecological hazard quotients that EPA reports in Section 4.2.1 for alternative A (no action) are much higher than BERA HQs. The residual risk assessment is also apparently inconsistent with the BERA in its use of “ecological hazard indices,” although this is unclear because EPA has not defined the term.*

**EPA Position:**

The 2016 FS was not attempting to replicate the BERA. There will be differences in the risks based on the methodology and data used. The BERA used biota data to assess the risk for RAOs 5 and 6 and used discrete river mile boundaries within the Site based on ecological exposures to aggregate the data. The 2016 FS is using sediment data to predict a tissue concentration using the FWM or BSAFs/BSARs and used incremental boundaries based on the same relevant exposure spatial scale as the BERA. Further, not all contaminants posing risk via this pathway were evaluated in the residual risk assessment due to the inability to correlate sediment concentrations with tissue concentrations. The disparity in HQs in the BERA and those in the residual risk estimate is due to the aggregation of the data and the models used to predict tissue concentrations. Further, the Respondents have not identified which ecological hazard quotients they believe are “much higher” than the BERA HQs. No “ecological hazard indices” are used in the 2016 FS.

*x. The residual ecological risk assessment is inconsistent with the BERA in asserting that riverbank soil poses risk. No analysis is provided to back up this assertion and no analysis of riverbank soils (as defined in the RI) were assessed in the BERA.*

**EPA Position:**

EPA agrees that the BERA did not assess risk from exposure to river bank soil in the BERA. The 2016 FS does not conduct a residual ecological risk assessment. The 2016 FS conducts an evaluation of residual risk under long-term effectiveness as required by the NCP and EPA guidance. The river bank soil/sediment poses a risk of recontaminating the sediment, which is where exposure occurs. As stated on p. 2-8 of the 2016 FS:

RAO 9 – River Banks: Reduce migration of COCs in river banks to sediment and surface water such that levels are acceptable in sediment and surface water for human health and ecological exposures. Reducing concentrations, exposure to, and the bioavailability of the COCs in river banks will reduce risk and recontamination at the Site. Ongoing source control efforts will provide additional risk and recontamination reduction.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*xi. Despite EPA providing few method details, these aspects of EPA's residual risk methods can be shown to be inconsistent with the BLRAs. This suggests it is highly likely that other details of the methods, if they were known, would also be inconsistent with the BLRA methods.*

**EPA Position:**

The methodology used to evaluate residual risk is provided in Appendix J of the 2016 FS.

*The fact that EPA finds the B and D RALs themselves (as well as a new "PTW" RAL) protective in certain areas of the site demonstrates that, as the LWG has previously commented, 17 EPA's approach does not narrowly tailor required cleanup activities to actual site risks identified through the risk assessments. EPA has selected some cleanup criteria that may be applicable to certain locations (or facies) and applied them inappropriately in others. For example, the use of TPAH RALs within the navigation channel is technically inappropriate because the BLRAs did not identify potentially unacceptable risk from this class of chemicals (beyond the extent to which benthic risk identified in the BERA may correlate with PAHs) except in nearshore areas where direct contact or shellfish harvesting might potentially occur. EPA's application of E RALs in some but not all parts of SDU 3.5E results in the identification of a Sediment Management Area for PeCDD where the current SDU 3.5 SWAC already meets the most conservative PeCDD PRG of 0.0002 ppb for RAO2 (fish consumption on a river mile basis). 18 In addition, the differential application of PAH RALs results in unjustified differential postconstruction risk. A larger remedial footprint results from the Alternative I using a 35,000 ug/kg TPAH RAL near outfall OF53A in SDU2E, whereas PAH-driven remedial actions in some other parts of the river have smaller footprints using a TPAH RAL of 69,000 ug/kg. The rationale for more extensive cleanup for PAH near OF53A and its net benefit is not explained.*

**EPA Position:**

First, the LWG's issue appears to inflate the role of the RALs versus the PRGs. The RALs are not cleanup criteria as the LWG categorizes them but rather different removal (dredging or capping) concentration levels of the focused COCs for alternatives analysis of risk reduction. Since RALs are not risk-based, it is reasonable to evaluate specific SDU characteristics, particularly the driver COCs to determine what level of active cleanup would result in the most cost-effective risk reduction.

In conducting the detailed evaluation of alternatives on smaller spatial scales in 2015, EPA realized that some areas of the river could require less aggressive active cleanup (more ENR/MNR) while other areas required more aggressive active cleanup (more capping/dredging). Different RALs were selected in various areas of the Site for Alternative I due to the attainment of PRGs based on specific RAOs in some areas upon completion of construction at the applicable spatial scale of the PRG. The basis for Alternative I using the RALs from Alternative B plus PTW concentrations were that only Alternative B was needed to achieve the cumulative risk interim goal in SDU 6NAV for RAO 2 (see Table 4.2-1); however, all PTW needs to be addressed to ensure the mobile

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

source material is reliably contained. The fact that EPA seeks to identify that some RALs would achieve a more protective post-construction risk reduction in some areas of the Site while others were necessary in other parts of the Site shows that EPA's approach does narrowly tailor the required cleanup activities to actual Site risks that the LWG argues should be done.

*Issue 3. Remedial Action Levels – The LWG disagrees with EPA's dioxin/furan, TPAH, and DDX RALs for reasons discussed below. Also, the problematic absence of any evaluation of benthic risks as part of alternative development in Section 3 is discussed in Comment 3d.*

*a. Dioxin/Furan RALs – The LWG does not agree that dioxin/furan RALs are necessary to define SMAs or select an effective remedy for the Site. EPA's Table 3.7-1 shows that the percent reduction in time-zero Surface-area Weighted Average Concentrations (SWACs) calculated by EPA for three dioxin congeners. The TCDD and PeCDD SWAC reductions for Alternative G are in the 60- to 70-percent range, which is a relatively low percent reduction as compared to the other RAL chemicals in the table. In contrast, the SWAC reduction for PeCDF starts at 89 percent for Alternative B and ends at 97 percent for Alternative G, which indicates that the range of RALs provides no meaningful differentiation in SWAC reduction for this congener. EPA has indicated (orally on August 27, 2015) that this is due to the paucity of data on detected dioxin/furan at the Site. However, the low data density and high non-detect frequency for the dioxin/furan dataset should be a reason to reconsider the value of dioxin/furan RALs, rather than a reason to explain the poor performance of such RALs. The insignificance of these SWAC reductions is more clearly illustrated by comparing the dioxin/furan SWACs achieved to EPA's own dioxin/furan PRGs by calculation of a SWAC exceedance factor—a factor above the PRG. This can be illustrated by comparing SWAC exceedance factors with and without EPA's proposed dioxin/furan RALs as shown in the tables below. The tables show that a RAL set that includes dioxin/furan RALs does not get the remedy meaningfully closer to acceptable risk levels as represented by EPA's PRGs. Details of this analysis can be provided. (EPA indicated orally on August 27, 2015, that EPA does not evaluate Site-wide SWACs, only SWACs on a rolling river mile basis. This is clearly incorrect given that the evaluation of each alternative in Section 4 starts with a presentation of Site-wide time-zero SWACs. Also, ~~EPA's own dioxin/furan PRGs are based on the osprey egg endpoint, which is assessed on a Site-wide spatial scale in the BERA.~~ [Sentence stricken per LWG request – see Attachment 1, 2015-10-08 FS Section 3 and 4 LWG Significant Issue Clarifications, 3<sup>rd</sup> bullet] Thus, the Site-wide spatial scale is actually the most relevant scale for an analysis of dioxin/furan RALs.) For example, for PeCDD, Alternative F without dioxin/furan RALs achieves SWACs 310 times greater than EPA's PeCDD PRG, while adding the dioxin/furan RALs achieves SWACs for this same alternative that are still 256 times above the same PRG. (Also, conducting this evaluation on a rolling river mile basis would not change this conclusion. Specific rolling river miles would range much further above the PRG than this Site-wide assessment.) Similarly, the addition of the dioxin/furan RALs only slightly reduces the SWAC exceedance factors for PeCDF and TCDD across all alternatives, and none of the alternatives are estimated to achieve SWACs that are below those PRGs.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*5 Per EPA's website*

*(<http://www.epa.gov/superfund/health/contaminants/dioxin/dioxinsoil.html>): "For example, the PRG calculated using the new RfD of 0.7 pg/kg-day (picogram per kilogram-day) and EPA non-adjusted exposure factors would be 50 parts per trillion (ppt) toxicity equivalence (TEQ) for residential soil and 664 ppt TEQ for commercial/industrial soil."*

*SWAC Exceedance Factor above the PRGs – without EPA's Dioxin/Furan RALs  
Alternative PeCDD PeCDF TCDD*

<b>Alternative</b>	<b>PeCDD</b>	<b>PeCDF</b>	<b>TCDD</b>
B	409	2.3	9.4
C	407	2.3	9.4
D	401	2.3	9.3
E	360	1.8	6.7
F	310	1.7	6.0

*SWAC Exceedance Factor above the PRGs – with EPA's Dioxin/Furan RALs  
Alternative PeCDD PeCDF TCDD*

<b>Alternative</b>	<b>PeCDD</b>	<b>PeCDF</b>	<b>TCDD</b>
B	354	2.1	6.6
C	341	2.1	6.5
D	314	2.0	6.3
E	293	1.4	5.8
F	256	1.3	5.5

*Also, for all of the dioxin/furan RALs EPA uses the exact same RAL numeric value to represent more than one alternative. For example, for TCDD, EPA proposes using the same RAL value of 0.002 µg/kg for Alternatives B, C, and D and the same RAL value of 0.0006 µg/kg for Alternative E, F, and G. This approach substantially constrains the alternatives from providing any meaningful changes in SWAC reduction or the SMA shapes and areas defined. Essentially, EPA is only providing three alternatives with regards to dioxin/furans. This appears to conflict with EPA's approach where the RALs (as opposed to technology assignments discussed in Comment 1) are the only real difference among alternatives. Thus, in the case of dioxin/furans, the alternatives have no variation in technology assignments and very little meaningful variation in term of RALs as well.*

**EPA Position:**

Section 5.2.3.1 of the RI Report states that the PCDD/F data set is limited (about one-fifth the size of other contaminant data sets) and cautions in making conclusions regarding the spatial patterns of the composition of total PCDD/Fs in sediment. Thus, EPA acknowledges there are limitations in how the RALs perform based on the current data. Based on existing data and the risk assessments, dioxins/furans pose the second greatest risk within the site to both human and ecological receptors. As such, the risks from this contaminant group must be addressed at the Site. The RALs for other focused

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

COCs do not sufficiently cover the dioxins/furans posing risk from exposure to sediment. However, the dioxin/furan sediment data collected by the Respondents is sparse and large areas of the Site were not sampled for dioxin/furans; thus, not characterized. The lack of data is not a basis for excluding these contaminants from the cleanup options presented in the 2016 FS. EPA explains in Section 3.4.1.2 of the 2016 FS the basis for some of the dioxin/furan RALs being the same in more than one alternative. Furthermore, the alternatives are developed as a combination of RALs, not individual RALs, and while the alternatives may not differ with respect to some of the dioxins/furans, they do differ with respect to other contaminants.

The 2016 FS only applies RALs where those concentrations are exceeded in sediment based on the RI data. As EPA has stated above, RALs are applied in combination to develop SMAs that cover all COCs in sediment greater than PRGs. EPA's applications of the E RALs in SDU 3.5E results in an estimated 1,2,3,7,8-PeCDD sediment concentration of 0.000125 µg/kg (see Table J2.3-7 in the 2016 FS). The 1,2,3,7,8-PeCDD PRG for RAO 2 is 0.0002 µg/kg (see 2016 FS Table 2.2-1). While the 1,2,3,7,8-PeCDD PRG is achieved post-construction for this alternative, other COCs are not. As shown in the 2016 FS, Table J2.3-8b, the residual risk for Alternative E in SDU 3.5E is  $1 \times 10^{-4}$ .

The 2016 FS developed dioxin/furan PRGs based on the relevant spatial scale for the RAO. Some of these are Site-wide, while others are at smaller spatial scales. However, in selecting PRGs for each of the RAOs, the most protective PRG is selected and applied at all relevant spatial scales.

*b. TPAH RALs – Per discussions at the 2014 FS technical meetings, the LWG disagrees that TPAH RALs should be used instead of cPAH RALs (expressed as BaPEq). BaPEq is consistent with the methods and results of the BHHRA, which were assessed in terms of total cancer risk from cPAHs on a BaPEq basis. Following the risk-based approach called for in the guidance,6 RALs should be consistent with the methods and findings of the BLRAs to ensure that sediment remedies are “risk-based” (i.e., result in effective risk reduction). Further, EPA’s latest Section 2 human health PAH PRGs are all expressed as BaPEq. Therefore, use of BaPEq RALs allows for a direct comparison on a consistent basis between the RALs and the PRGs, whereas TPAH RALs do not. Further, the use of BaPEq RALs for human health and Comprehensive Benthic Risk Areas (CBRAs)7 for ecological risks addresses all of the PAH-related potentially unacceptable risks found in the BLRAs. Also, the BaPEq RALs should only be applied to human health exposure areas outside the navigation channel consistent with the risk-based approach called for in the guidance. The cPAH risks related to sediment direct contact and shellfish consumption exposures occur only outside the navigation channel (along the shoreline), and as a result, BaPEq RALs associated with these potential risks should be applied in these areas only. The only remaining human health potential unacceptable risk identified in the BHHRA was for the fish consumption scenario, which was determined using cPAH concentration data in fish tissue. There is no valid relationship between cPAH fish tissue and sediment concentrations at the Site, or any other sediments site, due to the rapid metabolism of PAHs by vertebrate fish (see LWG 2014d, 2015a, 2015b for additional*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*details and references). Carcinogenic PAHs represent less than 1% of the cumulative risks to people eating fish and are, therefore, not a good reason to expand the remedy by hundreds of millions of dollars on the basis of a technically inappropriate PRG, given that there is no reasonable expectation that such an expansion could have any meaningful impact at all on the overall fish consumption risk. Because the BaPEq RALs can only be linked to effective risk reduction along the shoreline (using the BHHRA findings and the resulting appropriate PRGs for sediment direct contact and shellfish consumption), these RALs should only be applied along the shoreline outside of the navigation channel.*

*6 EPA guidance (2005a) discusses “Risk Management Principles and Remedial Approaches” and clearly describes that the cleanup should use a “risk-based framework”; “select site-specific, project-specific, and sediment specific risk management approaches that will achieve risk-based goals”; and “ensure that sediment cleanup levels are clearly tied to risk management goals” (p. 1 – 5).*

*7 See Comment 15 for more details on the LWG’s position regarding benthic risk and EPA’s removal of the CBRAs from the revised FS.*

**EPA Position:**

Polycyclic aromatic hydrocarbons (PAHs) are a group of over 100 different individual PAH compounds (ATSDR). Total PAHs were evaluated in the BERA and include the combination of 17 individual PAH compounds. The conclusions of the BERA was that total PAHs were ecologically significant at the Site (see BERA Table 11-5). There is nothing in the BERA that states that there is no risk from PAHs in the navigation channel. There is also nothing in the BERA that states that there is no exposure or risk to aquatic organisms in the navigation channel. To the contrary, the BERA identifies PAHs as a contaminant contributing to risk in almost every species evaluated in the BERA. The BHHRA only evaluated those individual PAHs which are cancer causing (16 individual PAH compounds). The BHHRA concludes that PAHs contribute to risk from consumption of fish in addition to risks from consuming shellfish and direct contact. The RALs are not risk based and are applied to all areas of the Site where they are exceeded. The evaluation of the alternatives evaluates those contaminants that are posing risk for each RAO by comparing the appropriate post construction contaminant concentrations to the PRGs for each RAO at the appropriate spatial scale in the Site. Residual risk and post construction risk for RAO 1 was not evaluated in the navigation channel since EPA agrees that this RAO is not applicable to that area of the Site; however, all other RAOs are and were evaluated in the navigation channel. RAOs 1 and 2 evaluate post construction cPAH concentrations to cPAH PRGs while RAO 6 evaluates post construction total PAH concentrations to total PAH PRGs. Additionally, there is no difference between the cPAH RALs developed by the LWG in the 2012 FS and the total PAH RALs used by EPA in the 2016 FS. EPA simply took the cPAH RALs developed by the LWG and converted them to total PAH using the regression analysis of the cPAHs at the site to total PAHs in sample pairs (see 2016 FS, Appendix D5).

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

The application of RALs in various parts of the river will result in differential post construction concentrations risks based on the remaining concentrations of different COCs in the area being evaluated. The basis for selecting E RALs for SDU 2E in Alternative I is based on the resulting residual risk from all COCs, not just PAHs. PCBs is the driving the risk in this area of the Site. As stated above, the RALs act in combination, not independently, in development of the alternatives. EPA is applying different alternatives (which are combinations of RALs) for Alternative I, not different individual RALs, in various parts of the river. The only area where D RALs was selected in Alternative I is SDU 6W. This area has a much greater SMA footprint from PAHs that SDU 2E since the PAHs are driving the risk in this area of the Site.

*c. DDx RALs – Although the LWG agrees with the use of DDx RALs as a general concept<sup>8</sup> instead of individual DDD, DDE, and DDT RALs in the 2012 draft FS, the LWG disagrees with the upper end of the RAL curve selected by EPA. There is little differentiation in the areas mapped using EPA’s B, C, and D RALs. For example, according to EPA’s Table 3.3-4, within the RM 7W area, the acreages defined by EPA’s DDx RALs for Alternatives B, C, and D are 10, 12, and 15 acres, respectively. EPA further indicates these RALs achieve Site-wide SWACs of 21, 20, and 19 ppb, respectively. Thus, this range of RALs represents virtually no substantial difference in areas remediated or risk reduction likely achieved. Instead, EPA should use DDx RALs of 8000, 1000, and 500 µg/kg for Alternatives B, C, and D, respectively. This RAL set would provide a wider differentiation between the active remediation acres and resulting SWACs achieved across these three alternatives. In addition, the LWG has the following specific concerns about EPA’s DDx RAL analysis:*

*i. Table 3.3-4 presents an inappropriate comparison of DDx RALs to a SWAC derived for a localized area of RM 6.6 to 7.8. EPA does not explain the basis for evaluating DDx across this area rather than an area that is consistent with the spatial scale evaluated in the BLRAs most related to appropriately calculated DDx PRGs. As noted above, RALs should be developed consistent with the BLRAs to be consistent with FS guidance.*

*ii. The LWG’s original position in 2011 was to use DDE RALs as a surrogate for DDD and DDT (and as a result, for total DDx). However, EPA expressed concerns in 2011 and again in 2014 FS technical discussions that the DDE RALs, by themselves, might not sufficiently bound areas of elevated DDD and DDT sediment concentrations. No supporting technical basis was provided by EPA for this concern, and none is provided in Sections 3 and 4. The determination of bounding COCs for RAL development is an evaluation that requires best professional judgment that must be clearly explained. In addition, the 2012 LWG draft FS indicates that potentially unacceptable risks associated with DDx are based only on the most conservative fish consumption pathway and are localized to RM 7, where DDx contributes only 3% of the cumulative potentially unacceptable risks. Given that EPA does not explain the reasons for the conversion from separate RALs to one combined set of DDx RALs, the LWG’s proposal above may not fully resolve the LWG’s concerns regarding EPA’s DDx RAL approach.*

*d. Comprehensive Benthic Risk Areas – EPA makes no mention of the CBRAs in the FS Section 3 text or how those risks are addressed through the proposed RALs and SMAs.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*See Comments 15 and 17 for more information regarding the LWG's position on benthic risk and need for consistency with the risk assessments.*

*8 However, the LWG does not necessarily agree with how EPA made the conversion from separate RALs to a combined DDx RAL or with the EPA's DDx RAL values as noted further below in this comment.*

**EPA Position:**

While the Respondents did not disagree with the use of DDx RALs, they are disputing the RALs used by EPA for Alternatives B, C, and D. EPA used the following RALs in the 2016 FS:

**Table 3.4-4**  
**DDx RALs with Resulting SWACs and Acres**  
Portland Harbor Superfund Site  
Portland, Oregon

Alternative	DDx				
	RAL (µg/kg)	RM7W		Site Wide	
		SWAC (µg/kg)	Acres	SWAC (µg/kg)	Acres
B	650	100	10	22	11
C	550	85	12	21	13
D	450	65	15	20	16
E	300	37	20	18	22
F	160	22	25	16	33
G	40	10	35	11	114
H	6.1	6	64	6	1,130

The Respondents argue that EPA should use DDx RALs of 8,000, 1,000, and 500 µg/kg for Alternatives B, C, and D, respectively, and that this RAL set would provide a wider differentiation between the active remediation acres and resulting SWACs achieved across these three alternatives. The current Site-wide SWAC for DDx is 52 µg/kg and the current RM 7W SWAC is 640 µg/kg. The suggested RALs from the Respondent would equate to the following SWACs and acres remediate:

Site-wide SWAC:

Alt	Rals	postSWAC	Acres
B	8000	38.72	1.22
C	5000	34.74	1.95
D	500	20.42	14.05

RM7W SWAC:

Alt	Rals	postSWAC	Acres
B	8000	373.9	1.22
C	5000	306.3	1.95

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

D      500    74.5            13.39

As the above analysis demonstrates, this contaminant is very localized in one area of the Site – RM 7W, as shown by the acres addressed by RALs. Table 3.4-4 and Figure 4.3-12 in the 2016 FS also shows this. Further, the LWG acknowledge this in their 2012 FS [**AR Doc # 706171**, Section 4.1, p. 4-4]:

Sum-DDE, particularly due to relatively localized potentially unacceptable risks near RM 7 to human health via fish consumptions (either smallmouth bass or large home range fish).

Sum-DDD due to relatively localized potentially unacceptable risks near RM 7.

Sum-DDT due to relatively localized potentially unacceptable risks near RM 7.

The B and C RALs only address contamination at RM 7W (as shown by the acreage Site-wide being the same as those at 7W). Very little area (1-2 acres) would be addressed using these RALs and the Respondents do not provide a basis for why selecting RALs at these concentrations would be meaningful in reaching the PRG of 6.1 µg/kg. Based on the uncertainty evaluation in the 2016 FS, Appendix I, the RALs suggested by Respondents for Alternatives B and C would not be statistically discernable from the no action alternative based on the variability of the data. Therefore, there would not be any “meaningful risk reduction” through selection of these RALs. Further, RALs are developed to address contaminant concentrations in the Site and are not based on risk – only PRGs are based on risk. However, the evaluation of the application of the RALs in reducing risk is conducted on spatial scales consistent with the baseline risk assessments.

EPA has had several discussions with the LWG and have provided comments regarding the use of DDE RALs dating back to June 2011. [**AR Doc # 100015899 and 100007242**] In all the discussions and comments provided by EPA between 2001 and 2015, EPA did not merely raise concerns but also provided technical information to support EPA’s determination that DDE RALs do not sufficiently address all risk from DDD, DDE, and DDT. EPA also provided a document presenting maps of RAL options to the LWG as early as July 27, 2011. [**AR Doc # 100033475, 663228, 663260**] Further, on August 11, 2011, EPA directed the LWG to use DDx RALs in the 2012 draft FS and the LWG did not dispute this direction at that time. [**AR Doc # 663242 and 663285**] The LWG never provided any information on why using DDE RALs as a surrogate for DDD and DDT is appropriate or reasonable. Both the BHHRA and BERA address risk to receptors as DDx; only the exposure to surface water used DDE, DDD, and DDT and bird egg assessments used DDE. The basis for using DDx is that it is directly comparable to the risks in the river and the only reason EPA developed RALs individually for DDD, DDE, and DDT were so the LWG could model them in their fate and transport model. The FS is a technical document that has the sole purpose of developing and evaluating alternatives and is not a document that is used to discuss the differences between the EPA and LWG

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

FS documents. EPA has had many discussion with the LWG over issues with their 2012 FS and have incorporated EPA's final determination on those in the 2016 FS.

*e. EPA indicates in Section 3 that the RALs were selected using RAL curves and considering the zone of maximum incremental SWAC reduction, the zone of marginal incremental SWAC reduction, the knee of the curve, and spatial distribution of the RAL points on the curve. The LWG generally agrees with these RAL selection criteria, which are similar to those stated in the 2012 draft FS. However, a cursory review of the RAL curves presented indicates a wide difference in the RAL points chosen along these curves across the various chemicals. Considering the EPA stated selection criteria either individually or together, there is no discernable consistency in the RAL points selected on the curve for one chemical to the points on the curve selected for another chemical. Thus, the stated selection criteria do not appear to be followed.*

**EPA Position:**

In the 2016 FS, there is no selection criteria for the RALs (refer to Appendix D1), as stated by the Respondents. EPA notes that there are points on the curves that are considered (the zone of maximum incremental SWAC reduction, the zone of marginal incremental SWAC reduction, the knee of the curve, and spatial distribution of the RAL points on the curve) but does not use these as rigorous selection criteria. The PCB and PAH RALs were selected by the LWG and carried forward into the 2016 FS. The DDX RALs are based on localized contamination and, therefore, the selection of RALs had to be carefully selected to ensure a broad range of footprints could be evaluated. The 2016 FS clearly describes the methodology for selecting the dioxin/furan RALs and why those differed from selection of the other RALs.

*Issue 15. Inappropriate Benthic Risk Analysis – EPA does not mention benthic community risks in the Section 3 RAL, SDU, or SMA development text (as noted in Comment 3). EPA must develop and evaluate alternatives that fully consider benthic risks using methods that are consistent with the BERA. Although EPA conducts an extensive SDU analysis to assess whether the selected RALs bound other risk pathways, EPA does not discuss the extent to which these RALs are expected to bound and address benthic community risks. In contrast, the 2012 draft FS included a detailed evaluation of and determination of benthic risk SMAs using the CBRA approach, as required by EPA at the time.*

*Then in Section 4, EPA evaluates the alternatives for their ability to adequately address benthic community risks. EPA concludes that all the alternatives do not address through active remediation a “substantial” portion of the benthic community risks. For example, EPA states for Alternative G, “There are a substantial number of locations where unacceptable benthic risk (identified via bioassays or predicted via the Logistic Regression Model [LRM]) are not encompassed by the areas of construction as shown on Figure 4.2-11.” EPA states that the remaining benthic risks will be addressed through MNR. While it is reasonable to address low-level risks through MNR (including benthic risks), EPA has constructed alternatives that ignore benthic risk and then demerits those*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*same alternatives in the effectiveness evaluation for failing to adequately address benthic risks.*

*EPA's benthic risk approach is particularly inconsistent given that EPA made multiple changes to the RALs between the draft and revised FS because EPA deemed the 2012 draft FS RALs for PAHs, DDE, and dioxin/furans as "not protective." This decision resulted in extensive work to recalculate all the SMAs and alternative quantities and costs. EPA does not attempt to explain in Section 4 whether EPA could have avoided all of this rework and instead similarly decided that MNR would address relatively low-level risks for PAHs, DDX, and dioxin/furans that EPA deemed were not directly addressed by the 2012 draft FS RALs. There are some important additional technical issues with EPA's benthic risk approach as follows:*

*a. EPA's method for defining benthic risks requires additional explanation. EPA provides one figure series (Figure 4.2-11 and Figures 4.2-14 through 17) and two statements regarding the methods used: 1) "Identified via bioassays or predicted via the LRM"; and 2) "Additionally, benthic risk is evaluated by determining the percentage of measured or predicted benthic toxicity points addressed by the construction of the alternative." The term "toxicity points" is new and not defined. Consequently, these results are not reproducible and the subsequent, related conclusions appear unsupported.*

*b. From examination of the cited figures, it appears that EPA used any instance of a Level 2 or Level 3 bioassay hit and any exceedance of the LRM benthic screening levels to determine that "benthic risk" was present at any given sampling station. The BERA is clear that individual benthic toxicity lines of evidence are insufficient to fully characterize benthic risks at the Site.*

*14 EPA guidance states:*

*"As a general policy and in order to operate a unified Superfund program, EPA generally uses the results of the baseline risk assessment to establish the basis for taking a remedial action using either Section 104 or 106 authority. \*\*\* If the baseline risk assessment and the comparison of exposure concentrations to chemical-specific standards indicates that there is no unacceptable risk to human health or the environment and that no remedial action is warranted, then the CERCLA Section 121 cleanup standards for selection of a Superfund remedy, including the requirement to meet applicable or relevant and appropriate requirements (ARARs), are not triggered."*

*In other words, where the baseline risk assessment concludes that a human or ecological receptor will not be exposed to potentially unacceptable risk by a contaminant present in a given media, there is no basis for taking remedial action. Where no remedial action is warranted, development or refinement of preliminary or final remediation goals is unnecessary. Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions, p.3 (OSWER Directive 9355.0-30, April 22, 1991).*

*15 See, LWG, List of Significant Issues with EPA's Revised FS Sections 3 and 4 (September 8, 2015), Issue 17 at pp. 44-48. (included within Attachment 1). The LWG's comments on the August 2015 FS are included as Attachment 1 and incorporated by reference.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*16 For example, the uncertainty analysis in Appendix I concludes that Alternative B is statistically indistinguishable from the no action alternative. This disagrees with figures in Section 4.2 that shows that the biggest drop in HQ and cancer risk is from the no action alternative to Alternative B as compared to the other alternatives.*

*17 See, LWG, List of Significant Issues with EPA's Revised FS Sections 3 and 4 (September 8, 2015), Issue 3 at pp. 9-13 (included within Attachment 1).*

*18 See, e.g., Table 4.2-1 of EPA's August 2015 FS.*

**EPA Position:**

EPA developed a comprehensive benthic risk area based on the PRGs for RAO 5 in the 2016 FS. This area is presented in Figure 4.4-1 and development of it is presented in Appendix D11. Section 3 of the 2016 FS discusses the development of the alternatives; evaluation of the alternatives, including how risks are addressed through the proposed RALs and SMAs, is discussed in Section 4. EPA did not use benthic risk as a basis for development of alternatives as EPA did not develop RALs for all other COCs. The focused COCs were chosen based on their coverage of other COCs, including those for RAO 5. None of the alternatives address all the risks at the Site through construction, with the exception of Alternative H. In the evaluation of alternatives in Section 4, EPA discusses those risks that are not addressed by the construction of the alternatives so that it is clear how much risk was addressed and how much remains to be addressed through MNR. EPA does not “demerit” or characterize this evaluation as a “failure” for any of the alternatives.

**LWG Dispute Issue 1e:**

*Other EPA revisions and changes between the August 2015 and June 2016 drafts of the FS that diverge without explanation from the RI and BLRA (and from each other) include:*

*On page 1-24, EPA identifies 66 COCs posing unacceptable ecological risks and determines that 20 of these COCs “pose risks ecologically high enough to consider development of a remedial action.” EPA presents no details of how this risk management decision was made and or how it is consistent with the Baseline Ecological Risk Assessment (BERA).*

**EPA Position:**

The BERA, in Section 11.4, presents Contaminants of Ecological Significance and concludes:

“All contaminants posing potentially unacceptable risk at the end of the BERA were recommended to be carried forward to the FS. Those classified as posing ecologically significant risk in Table 11-5 are recommended for consideration in developing and evaluating remedial action alternatives in the 2016 FS based on the pathways and factors considered in the BERA. Contaminants posing potentially unacceptable risk at the end of the BERA that are not listed in Table 11-5 are recommended for comparison with projected post-remedial action conditions to confirm that alternatives developed for the

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

ecologically significant contaminants would be protective for risks of low ecological significance.”

Therefore, this risk management decision was carried forward from the recommendation made in the BERA and is therefore consistent with the BERA. EPA made risk management decisions in Section 2 of the 2016 FS as to which COCs would be evaluated further in the 2016 FS (see Table 2.2-2).

**LWG Dispute Issue 1f:**

*The 2,4' and 4,4'-DDD, -DDE, -DDT (DDx) PRG for RAO 6 decreased substantially and is now based on sculpin tissue residue instead of sandpiper.*

**EPA Position:**

The DDx PRG for RAO 6 is based on the sculpin tissue residue (760 µg/kg) rather than the spotted sandpiper (2,849 µg/kg). As discussed by EPA in Section 2.2.2.2 of the 2016 FS (p. 2-11), the lowest PRGs was selected for each COC to ensure protection of all species.

**LWG Dispute Issue 1g:**

*EPA's proposed background values are still based on inappropriately derived upstream bedded sediment statistics that are unlikely to represent achievable cleanup levels for the site as they do not account for anthropogenic influences, which are known in the scientific literature to exist throughout the Willamette basin.<sup>19</sup> The FS also does not present background concentrations for surface water and does not present sediment background concentrations for all chemicals with sediment Preliminary Remediation Goals (PRGs).*

**EPA Position:**

Background calculations for sediment were developed as part of the Remedial Investigation Report, not the Feasibility Study, except for dioxins/furans. Under the RI/FS AOC, the LWG formally disputed EPA's directions on the statistical approach for calculating background. On March 24, 2015, EPA's Director of the Environmental Cleanup Office made a final decision on the methodology and statistical approach for calculating background and directed the LWG to calculate background for 23 contaminants using the methodology. [AR Doc # 500011627] We understand the LWG may continue to disagree with the methodology, but that issue is no longer subject to dispute under the RI/FS AOC. Since the RI report calculated background for dioxins/furans as total PCDD/Fs and TEQ and EPA was using dioxin/furan congeners for the analysis in the 2016 FS (see 2016 FS Appendix B2), EPA calculated the background concentrations for the congeners of concern to: (1) develop PRGs, and (2) conduct the evaluation of the alternatives in the 2016 FS (see Appendix B of the 2016 FS). EPA used the same methodology to calculate background concentrations for dioxin/furan congeners of concern as was used in the RI and consistent with the EPA Director's final dispute decision.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Neither the RI nor the 2016 FS presented background concentrations for all COCs in sediment because the RI report concluded that there were insufficient detections to determine background concentrations for 2,3,7,8-TCDD eq, aldrin, dieldrin, DDT, Lindane, and TBT. The exception is TPH-diesel in which a background concentration was calculated in the RI Report, Appendix H, but was inadvertently omitted from Table 2.2-9 in the 2016 FS. The background concentration is 61 mg/kg, which would not change the selection of the PRG, which is 91 mg/kg, since the risk-based number is greater than background.

EPA did not present background concentrations for surface water in the 2016 FS since there was insufficient data to statistically compute a background concentration (i.e., there was only one year where 3 seasonal data points were collected). Further, since surface water PRGs are based on ARARs, EPA would need to waive the ARAR, which means that significant information would be needed to show that achieving the ARAR is technically impracticable.

**LWG Dispute Issue 1h:**

*Sediment PRGs for RAO2 and RAO6 as well as riverbank PRGs for RAO9 for the five PCDD/Fs congeners are now all based on background concentrations. Background PCDD/F concentrations for individual congeners are presented in Appendix B, Table B2-4 of EPA's FS. The background values, however, are based on limited and poor quality data (with elevated detection limits) and involve taking the 95 UCL of detection limits for congener datasets based on all non-detects. In fact, only one congener has sufficient data (1,2,3,4,7,8-HxCDF) to calculate a background value and even that is limited (13 of 31 samples were non-detects). Thus, most of the background "values" are based on a 95% UCL of the detection limits rather than actual detections of contaminants. The background values are skewed quite low compared to those calculated for other urban watersheds and are of similar uncertain statistical validity.*

**EPA Position:**

The LWG now states that its upstream dioxin data is limited and of poor quality, yet when it submitted its draft RI report it represented that the data was sufficient and submitted background values for EPA to approve. LWG presented background statistics for 1,2,3,4,7,8-HxCDF, 1,2,3,6,7,8-HxCDD, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, 2,3,7,8-TDD, and 2,3,7,8-TCF in its 2011 draft RI report, essential using the same limited and poor quality data with elevated detection limits. Of these, the frequency of detection is greater than 50 percent for only 1,2,3,6,7,8-HxCDD, and is as low as 4 percent for 2,3,7,8-TCDF. Yet the LWG calculated a 95 percent upper predictive limit and a 95 percent upper confidence limit on the mean of the data for each dioxin/furan.

EPA determined that it was not appropriate to calculate upper confidence limits (UCLs) on the mean and upper predictive limits (UPLs) on data with such low frequency of detection, thus, background presented in the 2016 FS for these analytes was established as the 95th percentile of the detection limits. Because the background data set represented

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

“real life” data, EPA chose to establish background based on an upper limit of achievable detection limits.

**LWG Dispute Issue 1i:**

*And while EPA’s explanation of its development of its preferred Alternative I appropriately recognizes that Portland Harbor is a large and complex site where location-specific issues are important, EPA’s June 2016 FS continues not to resolve a number of the LWG’s prior questions about how EPA’s alternatives contribute to meaningful risk reduction at the site consistent with CERCLA and the NCP:*

*EPA’s calculation of PAH PRGs (and use of such PRGs for calculating post-construction risk) for minor or non-existent PAH fish consumption risk are not explained and not supported by the risk assessments.*

**EPA Position:**

According to information presented in the final BHHRA, fish consumption risks solely from PAHs are  $8 \times 10^{-6}$  for tribal consumers (assuming a site-wide averaged concentration and a 175 g/day consumption rate) and  $2 \times 10^{-5}$  at RM 5 assuming a consumption rate of 49 g/day. While these do not approach the  $1 \times 10^{-2}$  site-wide risk estimates, EPA, unlike the LWG, does not consider these risk estimates “minor or non-existent.”

The LWG has long maintained such risks are impossible, noting in the Bioaccumulation Modeling Report (2009 and 2015) that “fish metabolize PAHs.” LWG further claims (p.163 of Attachment 1 to the dispute statement) that “The LWG has previously pointed out to EPA that there is no relationship between concentrations of BaP in sediment and vertebrate fish at the Site or anywhere else, given that it is well documented that fish metabolize PAHs to a greater extent than invertebrates, and that “fish have been shown to rapidly metabolize 99 percent of PAH compounds within 24 hours of uptake,” thus “because fish metabolize PAH compounds so efficiently, fish tissue concentrations of PAH compounds have been deemed a poor means of assessing PAH exposure.”

EPA disagrees that fish tissue concentrations are a poor means of assessing PAH exposure. In fact, direct measures of contaminant concentrations in the actual media to which receptors are directly exposed is an excellent means of assessing exposure. The LWG has repeatedly made these same claims based on selective citations of literature for several years in direct contradiction of the data the LWG itself collected and its own evaluation presented to EPA in the BHHRA. A simple literature search returned documentation that PAHs do in fact bioaccumulate in fish. For example, Rose et. al. (2012) concluded that “PAHs were found in fish of all ages therefore this result suggests that fishes are exposed to and accumulate PAHs from the early stage of their lives through different developmental stages up to maturity and that sources of PAHs are present and available to fish in Lagos Lagoon due to regular discharges from several sources.”

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

**LWG Dispute Issue 1j:**

*EPA's calculation of PAH PRGs for direct contact are not explained and are not supported by the risk assessments.*

**EPA Position:**

PRGs for direct contact exposure (including PAHs) are clearly explained in 2016 FS Appendix B, Section B3.1.1. Because PAHs were evaluated only for carcinogenic effects for RAO 1, Equations B3-2 through 7 are relevant for calculating the PRGs. As noted, exposure values are summarized in Table B3-1, and unless otherwise noted, the source for each value is provided in Tables 3-21 through 3-25 in the BHHRA. As such, identical exposure assumptions were used when calculating the PRGs. The BHHRA evaluated risk due to exposure at specific, individual areas, and as noted in Section 3.5.8.6, a factor of 25 percent was used to account for the time spent fishing in a single area within the Site, which corresponds to a "site-use factor" of 4. While the application of site-use factor may be appropriate to assess the risk within a specific area, PRGs are intended to be applied to all beach and nearshore areas of the Site. Thus, if a receptor were to only be exposed to a single area, then a site-use factor would be appropriate, but when potential exposure at more than a single area is considered likely, use of a site-use factor is no longer protective. Due to the distribution of the contamination and the multiple uses and exposure points within the Site, EPA determined that it would not be protective to use a site-use factor.

**LWG Dispute Issue 1k:**

*There continues to be an issue with EPA's modeled dioxin/furan tissue concentrations. In the BHHRA, the site-wide risk from the total TEQ based on the 95%UCL or maximum concentration for actual tissue data was  $2 \times 10^{-4}$ . For Alternative A, the site-wide risk from 1,2,3,4,7,8-HxCDF alone based on an average concentration is  $6 \times 10^{-4}$ . There is no way that the risk from an individual congener can be higher than the total TEQ, and EPA's methodology therefore drastically overestimates the risk in a way that cannot be supported scientifically. The FWM is used by EPA to back-calculate concentrations of chemicals of concern (COCs) in sediment associated with acceptable, risk-based human health and ecological concentrations in fish tissue as calculated using the baseline risk assessment. This influences sediment PRGs and hence RAOs, so uncertainty originating with the FWM cascades, having compounding effects on the evaluation of remedy alternatives, and could result in additional remediation costs with no meaningful gains in risk reduction. We identify the following shortcomings with EPA's application of the FWM at the Site:*

*A comprehensive and detailed Conceptual Site Model (CSM) for the Site in total, and for the relationship between COC sediment and fish tissue concentrations specifically, has not been presented by EPA. This means that EPA's chief assumptions for the FWM related to steady-state conditions (in a flowing water body), the completeness of the site characterization dataset, regional contributions of COCs, and the apparent relationship between sediment and fish concentrations cannot be collectively synthesized in terms of their overall coherence and veracity.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Based on an examination of the empirical data for the Site, no statistical relationship is observed between sediment and fish tissue concentrations for DDX and PCDD/Fs at the concentrations relevant to risk decision making. This means that the FWM - which assumes such a relationship exists – is not reliable and that the conclusions reached on its basis are fundamentally flawed.*

*Good modeling practice was not used by EPA for the FWM, and in particular sufficient model documentation detailing the work does not exist. Adequate model documentation is one of several criteria used by EPA and other international regulators for determining the acceptability of a model for regulatory decision making (USEPA 2009, EFSA, 2014, Grimm et al., 2014).<sup>21</sup>*

**EPA Position:**

The calculated 95 percent UCL on the mean of the 27 individual 1,2,3,4,7,8-HxCDF SWACs shown in Appendix I of the 2016 FS is 0.26 µg/kg. Using the food web model the LWG calibrated for this COC, the estimated average tissue concentration is 0.046 µg/kg, which equates to a  $6 \times 10^{-4}$  risk, as shown in Table J2.3-1a of the 2016 FS. The discrepancy noted is likely due to limitations associated with extrapolating limited dioxin/furan sediment data site-wide, particularly when combined with the limited tissue data set. Respondents' assertion that the methodology is not "supported scientifically" represents a repudiation of the analytical tools they developed, and is otherwise simply a declarative statement unsupported by fact.

**LWG Dispute Issue 11:**

*The Food Web Model (FWM) used to calculate sediment PRGs from tissue PRGs was calibrated using PCB data. However, the model provided unachievable results for PCBs (zero listed in EPA FS Table 2.2-5 table). Predicting sediment PRGs using this model has even greater uncertainty for other compounds (e.g. DDX). This uncertainty effects the use of the model in the near field potentially more dramatically than at a site wide basis which is particularly evident where the sediment SWAC values are uncertain by an order of magnitude. Assessing model performance along the continuum of concentrations and scales of application (site-wide or near field) to assess the goodness of fit is necessary to evaluate whether model performance is acceptable, especially in areas of uncertainty in SWAC concentration at the low concentration range driving PRG derivations.*

**EPA Position:**

Respondent's dispute position appears to contradict their own voluminous record submitted to EPA supporting the use of a food web model for PRG development. The LWG's initial evaluation [AR Doc # 100004067] stated:

The primary goal of food web modeling for the remedial investigation/feasibility study is to develop a predictive relationship between chemical concentrations in sediment, water, and tissue that can be used to derive preliminary sediment cleanup goals for chemicals that are present in fish tissue at concentrations associated with unacceptable risk.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

LWG submitted a Draft Bioaccumulation Modeling Report to EPA in 2009, and again in 2015 with updated calibration for specific dioxin/furan congeners. [AR Doc # 500012795 and 100003827] In each submittal, the LWG stated:

With the Round 3 sampling program, which generated substantially more tissue and water chemistry data than were previously available, there are sufficient data to use the Arnot and Gobas model for other organochlorine pesticides besides DDTs. Using data from Rounds 1-3 sampling efforts, the Arnot and Gobas model was used for all organochlorine pesticide, PCB, and polychlorinated dibenzo-p-dioxin (PCDD)/polychlorinated dibenzofuran (PCDF) COCs.

In the LWG's April 23, 2015 responses to EPA's response to comments on Section 2 of the draft FS (submitted on p. 207 of respondent's Attachment to their dispute statement), they stated:

...the LWG agrees with the validity of the bioaccumulation model for use in calculating PRGs for the project (i.e., LWG is not challenging the accuracy of the model).

Further, the assumption of steady-state conditions is addressed in Appendix C of both the LWG 2009 and 2015 versions of the Bioaccumulation Modeling Report, which states:

Because of a lack of adequate time-dependent data for the Portland Harbor Study Area, the model has been simplified to assume steady-state conditions for the purposes of this application.

The LWG's Draft Bioaccumulation Modeling Report ultimately concludes:

Further, the mechanistic model can be used to estimate beyond the range of available data (e.g., to predict tissue COC concentrations lower than were found in collected fish samples). The Arnot and Gobas model explicitly accounts for the kinetics of chemical uptake and loss/dilution based on a mechanistic understanding of these processes. Because it is mechanistic, the model is appropriate for extrapolating beyond the empirically observed conditions in Portland Harbor, for example to project possible future conditions, to explore different assumptions about source terms (e.g., sediment versus lateral and upstream sources), or to calculate PRGs that fall outside the range of observed sediment concentrations. The fact that the Arnot and Gobas model is mechanistic also means that it can be calibrated to the data for a subset of chemicals and aquatic species and then "validated" with the data for other combinations of chemicals and species.

The mechanistic model was applied successfully for total PCBs, select dioxin/furan congeners, and pesticides including total DDx. For all chemicals, the model met or exceeded the stated objectives outlined in this document (i.e., SPAF < 3 for smallmouth bass and < 10 for other species). The calibrated model had SPAFs < 2 for smallmouth

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

bass for all modeled chemicals and generally < 5 for other species-chemical combinations (Section 5.4.1 and Section 6.3). Additionally, the model has been shown to perform well across a variety of chemical types (pesticides, PCBs, and dioxins), species (fish and invertebrates), KOWs, and spatial scales (Study Area-wide and smaller).

In conclusion, the bioaccumulation modeling presented in this report is suitable and reliable for calculating sediment PRGs for the Lower Willamette River.

EPA notified the LWG on November 18, 2014, that the food web model supplied to EPA in 2009 was approved. [AR Doc # 100005458] Thus, it is not clear why respondents' now claim that the food web model is not valid for calculating PRGs, when their 2012 Draft FS (Appendix Da, Attachment 1) states:

For the calculation of PRGs for sediment based on contaminant concentrations in tissue, the relationships between contaminant concentrations in sediment and tissue were evaluated using either the food web model (FWM) or through development of biota-sediment accumulation factors (BSAFs) or biota-sediment accumulation regressions.

Documentation of the Arnot and Gobas bioaccumulation model and its calibration, presented in Appendix B of the 2016 FS is adapted wholly from the report(s) submitted to EPA by the LWG. As noted, these submittals repeatedly assert that the food web model performs well for COCs other than PCBs (including DDX and specific dioxin/furan congeners), is suitable for calculating PRGs in sediment that are beyond the range of observed concentrations, and performs well at varying spatial scales. Absent a claim that information previously submitted to EPA in the numerous submittals referenced here were either erroneous or deliberately misleading, respondents provide no additional information that the food web model as developed by the LWG is not suitable to derive PRGs.

**LWG Dispute Issue 1m:**

*Section 2.2.1 of the FS, under ARAR-based COCs, states “contaminants that were detected in upland media (storm water and groundwater) that may potentially migrate to the river at concentrations that would exceed the Safe Drinking Water Act MCLs and national or State of Oregon water quality criteria were also designated as ARAR-based COCs.” This results in inclusion of PRGs for constituents not identified as a risk in the BHHRA. Further, it is inconsistent with EPA and DEQ rules to apply MCLs to porewater.*<sup>22</sup>

**EPA Position:**

Regarding identification of COCs as a general matter, EPA considered comments received from the LWG and others on this issue in developing the 2016 FS and modified its approach, particularly, with identifying human health surface water COCs. After reviewing the quoted text in Section 2.2.1 and reviewing the referenced Tables, EPA understands why there is confusion about how COCs were identified. Some text in the

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

2016 FS in Section 2.2.1 and the referenced Tables did not get updated to account for the changes in approach used in the June 2016 FS.

All COCs for RAO 3 are risk-based. The risk is mainly due to exceedances of contaminants in fish tissue; except for chromium and MCPP where the risk was based on the drinking water pathway. The BHHRA risk for the drinking water pathway was based on exceedances of Regional Screening Levels. [See Amended Tables 2.2-2 and 2.2-3a and 3b attached to this dispute].

For RAO 3, the PRG for MCPP was based on the RSL value, which is consistent with the BHHRA. However, EPA selected the MCL for chromium as the PRG rather than the RSL for hexavalent chromium. All other PRG values are based on national or State of Oregon water quality criteria (MCLs were all greater values and were not selected). Because the food web model assumed that surface water meets water quality standards in deriving the needed reductions in sediment concentrations to achieve protective fish tissue concentrations [2016 FS Appendix B1], surface water for the contaminants in fish tissue needs to achieve water quality standards (which is the basis for the PRGs for RAO 3).

The COCs for RAO 4 are all based on the identification of COCs in groundwater plumes (see Section 1 of the 2016 FS) and are based on MCLs and EPA RSLs for tap water. EPA RSLs were only used when an MCL was not available for a specific contaminant. The quoted text from the “ARARs-based COCs” was incorrect in stating that upland storm water data that exceeded an MCL or State water quality standard was used to identify ARAR-based COCs. The text should read:

National or State of Oregon water quality criteria, MCLs, and EPA RSLs for tap water were used to establish PRGs for RAOs 3 and 4. These values are presented in Tables 2.2-6 and 2.2-7. RSLs are only used when MCLs or other ARARs are not available for a specific contaminant.

EPA disagrees with the LWG’s long-standing position that exceedances of MCLs either in surface water or groundwater discharging to the river have no application to the Portland Harbor site. CERCLA Section 121(d) requires: (1) that any remedial action selected shall attain a degree of cleanup of hazardous substances, pollutants, and contaminants released into the environment and control of further releases at a minimum which assures the protection of human health and the environment; and (2) for any hazardous substance that will remain onsite, such remedial action shall require a level or standard of control which at least attains Maximum Contaminant Level Goals established under the SDWA, and water quality criteria established under Section 304 or 303 of the CWA. 42 U.S.C. Section 9621(d)(A)). The NCP provides that “[r]emediation goals shall establish acceptable exposure levels that are protective of human health and the environment and shall be developed by considering the following: [A] [ARARs] . . . [B] . . . [MCLGs] . . . [E] Water quality criteria established under sections 303 and 304 of the Clean Water Act . . .” 40 CFR Section 300.430(e)(2)(i)(A), (B), and (E).

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

CERCLA and the NCP are clear that MCLs are to be achieved in contaminated groundwater and surface water at a site when relevant and appropriate under the circumstances of the release. MCLs are relevant and appropriate under the circumstances of the release at Portland Harbor because the designated uses of the lower Willamette River include drinking water supply. (Designated Uses for the Willamette Basin specified for the Willamette Basin at OAR 340-041-340 and 340-041-0345.) Likewise, all groundwater of the state, including the groundwater adjacent to and under the lower Willamette River, are to be protected for the beneficial use of domestic drinking water supply. (OAR 340-040-0020(3)), which is as stringent or more stringent than the “EPA Guidelines for Ground-Water Classification” (December, 1986) (See 55 FR 8732, March 9, 1990). Releases of hazardous substances have occurred to groundwater that is discharging to or under the river within the Site or has the potential to discharge to the river which exceed applicable promulgated water quality standards and relevant and appropriate Safe Drinking Water Act standards for groundwater and surface water cleanup. Therefore, it was appropriate for EPA’s 2016 FS to identify COCs and set PRGs based on MCLs for groundwater and surface water at the Portland Harbor Site. The LWG claims MCLs should not be applied to pore water. However, under the circumstances at this site, both groundwater and surface water are potential drinking water resources, and discharges of contaminants to the river represents one continuous pathway. Therefore, there is no basis to distinguish pore water from groundwater or surface water in regard to where compliance with the ARAR should be met.

**LWG Dispute Issue 1n:**

*EPA continues to identify Regional Screening Levels (RSLs) as PRGs. For example, RAO 4 incorporates the tap water RSL for Manganese. That current manganese RSL is derived from outdated toxicity evaluation without clear adverse effects. A more recent and credible source of toxicity information (ATSDR 2012) concludes that an oral threshold value for manganese cannot be derived. Use of outdated and poorly supported toxicity criteria is inconsistent with EPA guidance.*

**EPA Position:**

The RSL for manganese was calculated using the oral reference dose (RfD) developed by EPA’s Office of Research and Development and posted in its Integrated Risk Information System (IRIS) database. Consistent with EPA guidance (EPA 2003), the toxicity values developed by the IRIS program represent Tier 1 values. This guidance states that “in general, if health assessment information is available in the Integrated Risk Information System for the contaminant under evaluation, risk assessors normally need not search further for additional sources of information.” ATSDR minimal risk levels represent Tier 3 values in the recommended hierarchy. Further, respondents’ assertion that the evaluation is “without clear adverse effects” mischaracterizes the information provided in both the IRIS and ATSDR assessments of oral and inhalation toxicity of manganese. While acknowledging that manganese is essential in the function of several enzymes, IRIS notes that “several disease states in humans have been associated with both deficiencies and excess intake of manganese.” Epidemiological data evaluated “raises

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

significant concerns about possible adverse neurological effects at doses not far from the range of essentially.” Thus, given its role as an essential nutrient and the ubiquitous nature of manganese intake in the general population, development of the RfD focuses on what is known to be a safe oral intake of manganese for the general population, which is consistent with the definition of the RfD. Further, while respondents note that ATSDR chose not to derive an oral MRL for manganese, they fail to note that it recommend use of an “interim guidance value” of 0.16 mg/kg-day to be used for ATSDR public health assessments of oral exposure to inorganic forms of manganese. The ATSDR recommendation is essentially the same as the 0.14 mg/kg-day RfD from IRIS.

**LWG Dispute Issue 1o:**

*EPA’s FS states, “Compliance with ARARs is determined by whether an alternative will meet all of the chemical-specific, action-specific, and location-specific ARARs and/or those that are to be considered (TBC) identified in Tables 2.1-1 through 2.1-3.” Table 2.1-1 identifies EPA Regional Screening Levels for groundwater as TBC values. “TBCs are not ARARs ... but may be considered and used as appropriate, where necessary to ensure protectiveness.”*

**EPA Position:**

The FS statement and the CERCLA Compliance with other Laws Manual are not inconsistent. A more complete quote from the CERCLA Compliance with Other Laws Manual indicates that chemical-specific TBCs can be surrogates for ARARs when needed to ensure protectiveness:

TBCs are not ARARs, but chemical-specific TBC values such as health advisories and reference doses will be used in the absence of ARARs or where ARARs are not sufficiently protective to develop cleanup goals (see discussion of risk assessment in Section 1.2.3.1 below). In addition, other TBC materials such as guidance or policy documents developed to implement regulations may be considered and used as appropriate, where necessary to ensure protectiveness.

It is not inconsistent with the NCP to evaluate whether remedial alternatives will achieve chemical-specific, numeric TBCs identified in the 2016 FS as PRGs. “Overall protection of human health and the environment draws on the assessments of other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs.” [40 CFR 300.430(e)(9)(iii)(A)]. Nonetheless, only PRGs based on ARARs were the basis for EPA’s determination in the 2016 FS that Alternatives B and D would not meet the second threshold criteria. The ARARs analysis of the alternatives was based on the mass balance analysis contained in Appendix K to the 2016 FS. The Appendix K analysis only looked at COCs that were in sediment and their effect on surface water using a mass balance approach. All of the PRGs for RAO 3 analyzed in Appendix K are based on national recommended ambient water quality criteria developed under the CWA or Oregon’s water quality standards, no TBCs. MCPP (which is the only PRG for RAO 3 based on the RSL TBC) was not evaluated in Appendix K because there

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

are no sediment exceedances. Therefore, the determination that Alternative B and D would not meet all ARARs did not use TBCs.

**LWG Dispute Issue 1p:**

*EPA establishes a PRG for total chromium; however, only hexavalent chromium was identified in the human health risk assessment as potentially posing unacceptable risk.*

**EPA Position:**

Hexavalent chromium was identified as posing unacceptable risk via use of surface water as a drinking water source for both the RME and CTE evaluations. The risk assessment used the EPA RSL of 0.035 µg/L. Consistent with the NCP [40 CFR 300.430(e)(2)(i)(B) and (C)], the PRG for a drinking water source was set at the MCL, which is for chromium. The MCL for chromium is 100 µg/L. As stated in the 2016 FS, RSLs were only used where MCLs were not available. The risk management decision in the 2016 FS was that use of the MCL was sufficient to protect for risks from hexavalent chromium. It is noted that if a risk-based PRG for hexavalent chromium were derived it would be four orders of magnitude lower than the MCL.

**LWG Dispute Issue 1q:**

*The RI and BLRAs do not provide information or a foundation for establishing cleanup goals or remedial actions for source control. The LWG has previously commented that EPA should not establish PRGs or RAOs for source control media that were not assessed in the BLRAs or RI.*

*The June 2016 FS uses a new rationale for including riverbanks in the FS. “Since river bank contaminations (sic) are directly linked to the sediment bed and receptors through proximity and source and migration pathways, the known areas of contamination are included here and elsewhere in the FS. Including these areas supports the evaluation of and selection of alternatives in case it is determined that river bank contamination is best suited for remediation in conjunction with in-river activities.” This new rationale does not address the LWG’s prior stated concerns.*

*The FS references an attached riverbank database, but the database was not included. Consequently, the Disputing Respondents continue to have no way to verify any of EPA’s FS decisions regarding remediation of the river banks. Regardless, prior LWG issues with EPA’s source control approach remain. These issues include that PRGs should not be established based on exposure pathways being evaluated in upland source control evaluations under DEQ oversight, and that none of these upland media were evaluated in the BLRAs or Remedial Investigation (RI). EPA’s use of sediment PRGs for riverbanks, even on areas rarely inundated and without considering attenuation, is technically inappropriate. Delineations of groundwater plumes and riverbanks, and a zero post-construction restoration time frame are arbitrary. There is a total lack of data and analysis as to what risk considerations are driving the specific remedial actions delineated (and therefore how this will be refined in the design phase when further data/analysis is available) and what specific remedial actions will be implemented in*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*which areas driven by those risks. This arbitrary delineation is then carried forward into the evaluation of alternatives and given weight for assessing the relative effectiveness of alternatives. Further, the last-minute incorporation of riverbanks in the FS, when they have not been fully delineated, is counter to EPA policy and guidance.*

*In February 2001, a Memorandum of Understanding related to the Site was executed among EPA, Oregon DEQ and several state, federal and Tribal natural resource trustees. That MOU provided that EPA would be the lead agency for investigating and cleaning up contamination in the river sediment and DEQ, using state cleanup authority, was designated as the lead agency for identifying and controlling upland sources adjacent to or near the river. Pursuant to that MOU, the Portland Harbor Joint Source Control Strategy was finalized by EPA and DEQ in December 2005. Since that time, many owners and operators of facilities along the river, including several of the Disputing Respondents, have been actively involved with DEQ, planning and implementing source control measures. In the FS, EPA has ignored many of those fully or partially completed actions and identified groundwater and riverbank concerns that in some instances simply don't exist anymore, and in others are sites where property owners have agreed upon remedies to be implemented under DEQ oversight at or before the time of the in-water remedy. There is no reason for EPA to now both ignore and undermine those efforts by inserting RAO 9 into the FS, ignoring completely the DEQ Upland Source Control Update Summary Report most recently updated by DEQ in March 2016.*

*Several site-specific examples of errors arising from EPA's determination to select remedies for riverbanks without any foundation in the RI or risk assessments are set forth in the Appendix, attached and incorporated herein. To take a representative example, the FS does not account for upland work already performed by NW Natural at the Gasco facility pursuant to its DEQ Voluntary Agreement and in close coordination with EPA, the result of which leads to EPA to include presumptive excavation with presumptive cover material along the entire Gasco Sediments Site riverbank in all alternatives. This presumptive riverbank remedy is not supported by technical rationale, prevents meaningful comparison of the performance of technologies and limits the evaluation of multiple technologies that may perform equally effectively, is inconsistent with the range of technology assignments evaluated along different portions of the Gasco Sediments Site riverbank in the May 2012 Gasco Engineering Evaluation/Cost Analysis, and does not account for known impacts that will occur to existing upland structures and potential future upland source control structures. Similarly, The FS ignores that Gunderson has implemented permanent riverbank source control measures at some riverbank areas that are identified by EPA as needing remediation under the oversight of the Oregon DEQ and in accordance with the requirements set out in the DEQ-EPA Portland Harbor Joint Source Control Strategy. Gunderson has also completed interim source control measures under DEQ oversight at the remainder of the riverbank areas that are identified by EPA in the FS and agreed that additional permanent measures will be implemented concurrent with the adjacent in water remedy. And the FS ignores the riverbank remedial action implemented by Evraz at its Rivergate property, a remedial action based on a*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*source control decision made by the Oregon Department of Environmental Quality and concurred with by EPA.*

**EPA Position:**

The LWG did not provide any legal or technical basis for its position that EPA should not address river banks as part of the in-river response action. The LWG argues the river banks are a different media that was not evaluated in the risk assessments, thus, EPA cannot or should not address them. Although soils may be a different “media” from sediment as a general matter, the LWG’s argument ignores the site-specific facts at this Site. The baseline risk assessments determined there was unacceptable risk to human health and the environment from multiple contaminants found in surface water, sediment, groundwater and tissue. Many of those same contaminants, plus other contaminants that have been found to exceed ARARs in groundwater, are detected the river bank soils (both surface and subsurface) exceeding the PRGs for sediment, groundwater and/or surface water. The data gathered by ODEQ on the river banks is in the administrative record (See Appendix A to the 2016 FS). Maps 3.4-14a-h in the 2016 FS illustrates that the contamination in the river banks is immediately adjacent to and at most locations likely a mere extension of the contamination in the river. Currently the contamination in the river banks is uncontrolled and either is migrating or has the potential to migrate to the river. There are tidal fluctuations twice daily, submerging portions of the river bank throughout the day potentially exposing aquatic receptors to the river bank contamination. Furthermore, the river water levels rise and fall seasonally, thus, again submerging different portions of the river bank throughout the year. Other forces, sheet flow, gravity, or upland land uses, can lead to river bank soils eroding into the river. CERCLA and the NCP provide EPA with broad authority to take response action on releases or threatened releases of hazardous substances to the environment. The river banks as well as all upland sources are within the boundaries of the Portland Harbor Superfund Site. There is sufficient information and foundation in the 2016 FS and administrative record to support EPA taking action on river banks as part of the in-river portion of the site.

The 2001 MOU between EPA, ODEQ, Tribes and Federal and State Trustee agencies established the framework for roles and responsibilities for addressing the Portland Harbor Superfund Site. [AR Doc # 1128679] The MOU is an administrative tool and framework for coordination between all of the government agencies involve with the site. Section IV. A.1. of the MOU provides that DEQ is designated Lead Agency for the upland portion of the Site. EPA will be the Support Agency. The MOU further provided that “DEQ may elect for any reason to ask EPA to assume the Lead Agency role for any discrete facility(s) or portion(s) of the upland portion of the Site at any time.” Furthermore, Section VII.D. states that: “The Parties recognize that each Party reserves all rights, powers, and remedies now or hereafter existing in law or in equity, by statute, treaty, or otherwise. Nothing in this Agreement is or shall be construed to be a waiver of the sovereignty of a signatory Party. This Agreement is intended solely for the purposes of facilitating inter-governmental cooperation between the Parties, and creates no rights in third parties or the right to judicial review.” EPA retains all of its authorities to address any portion of the Portland Harbor site.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

The inclusion of river banks was not last minute. In fact, DEQ requested we address some river banks as far back as 2012. **[AR Doc # 100013966 and 100013967]** Riverbanks were included in the 2015 version of the FS that the LWG was provided to comment on. The LWG was provided drafts of EPA's Section 1 of the FS, which identified river banks in early 2014. EPA identified contaminated river banks adjacent to in-river SMAs in coordination with ODEQ, who is the support agency for this Site and oversaw the collection of the river bank data. EPA sought ODEQ's input on the information presented in Section 1 of the 2016 FS. **[AR Doc # 100009725, 100009726, 100005299, 100005300, 100005518, 100005534 and 100005537]**

Furthermore, the SMAs are based on RALs, not PRGs, and were extended from in-river sediment to those river banks that were identified as contaminated since it is likely that those river banks are sources of the sediment contamination and are equally, and likely more, contaminated than the in-river sediment. The LWG provides no evidence contamination in river banks would significantly attenuate prior to exposure to in-river receptors or migration to the completely submerged portion of the river. To the contrary, known facts are that the contaminants being evaluated do not readily degrade and there is no deposition occurring on riverbanks or most SMAs adjacent to the riverbanks. Further, if there are concentrations in the river banks that exceed sediment PRGs, then they have the potential to erode and recontaminate the sediment. The delineation of groundwater, river banks, and sediment are all based on limited data and EPA agrees that refinement of these areas will need to be conducted in remedial design.

Source control actions are interim actions conducted under DEQ authority are not final CERCLA actions. EPA will evaluate the effectiveness of any source control actions conducted under DEQ authority with final remedy objectives and making the determination as to whether further action is warranted if significant risk of recontamination is found. Where early source control actions meet the requirements of the ROD, then EPA will not require further action to be taken in those areas. EPA cannot make such a determination in the FS, as it predates the ROD, but EPA did assume that all sources, other than river banks and groundwater plumes extending beyond an upland control measure, are controlled in the 2016 FS for purposes of determining what amount of sediment cleanup would be required to be protective of human health and the environment. Therefore, contaminated riverbanks that could recontaminate the in-river cleanup and upland groundwater plumes that are beyond the upland control point need to be addressed by the in-river remedy.

**LWG Dispute Issue 1r:**

*The Feasibility Study is the appropriate point for EPA to bring in risk management principles. EPA's sediment guidance directs that cleanup objectives "should reflect objectives that are achievable from the site cleanup." The FS should therefore focus on those chemicals and cleanup levels that are technically practicable to be reached through a sediment remedy based on site-specific considerations.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Equilibrium. A sediment remedy must include evaluating what is deposited within the Study Area, both physically and chemically (i.e., potential future bedded sediment equilibrium). EPA has not conducted such an evaluation. The assumption that background sediment concentrations are the same as equilibrium is invalid. The cleanup goal for PCBs of 9 parts per billion (ppb) based on EPA's calculation of background concentrations is not achievable or sustainable by existing technology nor by nature itself. Experience gained at other sediment remediation projects conducted nationally and in Region 10 strongly argue that background should not be used to establish cleanup goals when likely ongoing contaminant inputs from upland sources within the Site and upriver of the Site exceed EPA's calculation of background. The LWG provided EPA an evaluation of equilibrium concentrations for the Site. Equilibrium is the only reliable indicator of future concentrations that can be achieved.*

*Perhaps the most important certainty at the Site is that the Lower Willamette River flows from south to north. As part of the flow, the river carries sediments which are deposited within the Site. Equilibrium is controlled in large part by concentrations of contaminants in the incoming sediments from upstream. This creates a bounding condition such that no amount of active remediation within the Site can achieve or sustain concentrations lower than that of the equilibrium level. Based on relevant empirical data collected by the LWG, no sediment remedy is likely to achieve PCBs lower than 20 ppb in the foreseeable future.*

*Realistic Exposures. As described in the Sediment Guidance: "A risk management process should be used to select a remedy designed to reduce the key human and ecological risks effectively." One of the fundamental flaws in the FS is the absence of any explicit, documented risk management. The term "risk management" is never used in the June 2016 FS or the Proposed Plan. Risk management in the Superfund program requires the consideration of the advantages and disadvantage of cleanup alternatives and balancing of trade-offs. This analysis includes an evaluation of the uncertainties at the Site, including uncertainties in the reliability of the exposure data used to identify the risks. One of the key factors in decision-making is: "[t]he likelihood of the exposure actually occurring should be considered when deciding the appropriate level of remediation, to the degree that this likelihood can be determined." At Portland Harbor, the risk assessments, particularly for human health, are built on a cascade of unrealistic and improbably conservative assumptions regarding exposure and durations. Unacceptable risks to various consumers of fish are based on questionable assumptions of how many resident fish people eat, from which areas of the river, how the fish are cooked, and for how many years any one person eats them. The assumptions are not placed in an overall estimate that is conservative but within a realistic range of exposure, as required by the NCP. EPA's description of this risk – people should eat no more than 6 fish meals every 10 years – is not well explained in terms of the exposure assumptions supporting the risk and those locations within the Site that actually pose an unacceptable risk for consumption of resident fish. Further, the assumptions are not comparable to assumptions used at other large sediment sites.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*And, most important, EPA's June 2016 FS fails to document how the risk assumptions have been considered when evaluating alternatives. Nowhere in EPA's FS are the exposure assumptions with respect to risks from fish consumption expressly stated. Rather, the FS simply describes astronomical risks at the Site and the extraordinary measures needed to address such largely illusory risks. The absence of such information in EPA's FS demonstrates that an important element of risk management -- the reliability of the exposure assumptions -- has not been sufficiently considered.*

*Finally, the FS does not identify which areas of the Site currently pose the highest risk and should be prioritized for remediation. At a 10-mile Site that, according to EPA's FS, encompasses nearly 300 acres requiring active remediation and likely close to 20 years to perform, it would seem necessary and prudent to establish a basis for prioritizing and sequencing the cleanup of the higher risk areas. EPA's failure to do so shows that it is not effectively managing the actual risk.*

**EPA Position:**

EPA guidance does not require an evaluation of equilibrium; however, EPA did evaluate equilibrium at post construction. EPA endorses the concept of equilibrium, however, the necessary information (sediment trend data) is not available to conduct an equilibrium evaluation in the long-term. EPA has developed background concentrations consistent with EPA policy and guidance. EPA has further looked at the sediment traps deployed in the upriver reach, which corroborate the values developed from the upriver sediment. The scatter plots of PCBs from the RI Report (Figure 5.2-1) shows that there are concentrations within the site that are already at or approaching the calculated background concentration of 9 µg/kg. EPA has been coordinating with DEQ on source control actions in the downtown reach and upland areas of the Site to ensure that sources will be sufficiently controlled that they will not recontaminate the Site. Therefore, there is no information available that indicates that background concentrations would not be achievable. Further, the lower Willamette River does not flow with certainty from south to north. There are several instances where the river flow reverses, which is an important aspect of the CSM and has been acknowledged by the Respondents (see LWG draft RI 2011, **AR Doc # 10006009**). The equilibrium evaluation conducted by LWG included sources that are being controlled under DEQ authority; thus, EPA deems that evaluation not relevant to current Site conditions.

Appropriate risk management was applied in the 2016 FS. The fact that there is no overt "risk management" section in the 2016 FS, or that EPA arrived at different conclusions than did the LWG in their 2012 draft FS, Appendix E (which was rejected by EPA), does not mean that such information was not considered in the development of the remedial alternatives in the 2016 FS, not the least of which was to assign MNR to the vast majority of the site in areas where contaminant concentrations – and thus the relative risk – are lower than within the SMAs.

EPA is well aware of the LWG's objections to the risk assessment, including assumptions regarding fish consumption, on which they previously invoked the formal dispute process

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

under the AOC. Respondents are referred to the final dispute decision for resolution regarding these issues. [AR Doc # 715198 and 715199] We do note the contradiction here with other sections of the LWG's FS dispute that argue that analyses presented in the 2016 FS need to be consistent with the approved risk assessments. But here respondents request that the approved risk assessments be discarded or simply ignored in the name of "risk management," Respondents' did in their draft 2012 FS, leading to their conclusion that "there is sufficient scientifically valid evidence that baseline conditions might already meet the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) threshold criterion for overall protection of human health and the environment." And while the purpose of the FS is not to once again recreate the risk assessments, exposure assumptions for all pathways are provided in Table B3-1 of the 2016 FS, areas of the Site that pose unacceptable risk (defined as sediment concentrations exceeding risk-based PRGs) are presented in Figure 2.2-2 of the 2016 FS. Finally, Section 3.4.1 of the 2016 FS defines SMAs as "areas with the most widespread contaminants that pose the highest risks," which are targeted for remediation through constructed remedial technologies.

**LWG Dispute Issue 1s:**

*EPA does not explain its conclusion that Alternative B alone fails to comply with ARARs. Although EPA's August 2015 FS found that all alternatives met ARARs, this FS concludes that Alternative B would not meet certain water quality criteria. It is unclear how EPA reaches this conclusion only as to Alternative B, since EPA states elsewhere that it lacks information to evaluate the effectiveness of meeting these criteria for any of the alternatives under consideration.*

*Information in the RI demonstrates that surface water quality criteria for some COCs (e.g., PCBs and D/F) will never be met by any sediment cleanup at the Site because of upstream concentrations. EPA notes on page ES-17 of the FS, "It is expected that MNR in conjunction with ICs and source control, including control of upriver sources, is necessary to achieve surface water RAOs."*

*Similarly, MCLs are likely not achievable throughout the spatial extent of some groundwater plumes along the shoreline or out under the river, and achievement of such criteria are not necessary to design and implement groundwater and sediment remedies that are protective of all reasonable and likely future uses of groundwater. EPA should either determine that MCLs are not applicable, relevant or appropriate because MCLs do not apply to the groundwater in this context, or it should waive these water quality criteria ARARs now. MCLs are not applicable, relevant or appropriately applied to groundwater here because the Oregon statute designates the Lower Willamette River as a potential public and private water supply only following adequate pretreatment and because the federal Safe Drinking Water Act under which MCLs are developed designates that drinking water is appropriately sampled at the point of distribution.*

**EPA Position:**

The 2016 FS Section 4.2.2.2, pp 4-20 to 4-21 states:

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Exceedances of water quality criteria for protection of human health from contaminated sediment within the Site would continue for PCBs, cPAHs, and 2,3,7,8-TCDD eq at the completion of construction. There is insufficient surface water data to evaluate the effectiveness of this alternative in meeting the aquatic life water quality criteria for BEHP, PAHs and TBT. All other chemical specific ARARs are achieved with this alternative. Ethylbenzene from contaminated groundwater is expected to be addressed to achieve RAO 8 through implementation of source control measures. However, Alternative B only addresses 16 percent of the sediments impacted by groundwater. Alternative B, in conjunction with adequate upland and upriver source control measures, would not achieve numeric human health and aquatic life water quality criteria and drinking water MCLGs and MCLs. Long-term monitoring and maintenance of engineering controls, pore water, and surface water assist in evaluating the ability of this alternative to achieve chemical specific ARARs.

In conducting the analysis of achieving water quality ARARs from sediment remedial actions in the Site, EPA separated the upriver and downtown contributions of contaminants from the Site contribution of contaminants (see Appendix K and Figures 4.2-8a and f for PCB and dioxin/furan evaluation, respectively). EPA states in all alternatives (including Alternative B) that it lacks the information to conduct an analysis on smaller spatial scales and for RAO 7 PRGs. However, an analysis was conducted for RAO 3 PRGs on a site-wide scale. EPA's analysis shows that Alternative B does not sufficiently reduce the load of contamination from sediment to surface water such that water quality ARARs could be achieved.

See EPA position on LWG dispute issue 1g regarding background for surface water.

Please see EPA position on LWG dispute issue 1g for the legal bases and site-specific reasons why MCLs are relevant and appropriate to releases at this Site. There has been no information or analysis provided to the EPA to date that supports a waiver of MCLs at this site. It is EPA's expectation that DEQ's upland source control actions will adequately address groundwater contamination (the plumes). EPA's RAOs are focused on containing and reducing migration of COCs from groundwater to surface water and biologically active areas of sediment. Should groundwater not be addressed adequately under DEQ's actions, EPA may, at a future time, determine if action is warranted under CERCLA to further address groundwater contamination. [Section 2.2 of the 2016 FS] Likewise, if during remedy implementation it is discovered and demonstrated that achieving MCLs is not technical practicable a waiver of that ARAR may be found necessary. [Section 2.1.2 of the 2016 FS]

**LWG Dispute Issue 2**

***EPA's June 2016 FS continues to lack complete and transparent evaluation of the long and short-term effectiveness and cost of its alternatives, as well as of the degree to which those alternatives reduce the toxicity, mobility or volume of hazardous substances through treatment, including treatment of PTW.***

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

**LWG Dispute Issue 2a:**

*EPA's inadequate conceptual site model does not provide a foundation for a thoughtful comparative evaluation of alternatives. The June 2016 FS does not sufficiently describe the relevant Site features, baseline risks, role of sources, fate and transport, and site uses and other important factors necessary to understand the potential cost effectiveness of various remedial technologies or EPA alternatives. Information on contaminant fate and extent is completely missing from the CSM discussion. In fact, the site has been characterized by EPA based on aggregated sediment data without regard to time dependent changes that reflect the kinetics of rate and extent operating in this system. It is not possible to accomplish a valid alternatives evaluation without an adequate operationalized theory and model of the site. The LWG previously commented that EPA's August 2015 draft FS needed a more balanced presentation of all sources in Section 1 (groundwater, riverbank, and stormwater). Again, this FS neglects to include a discussion of stormwater sources to the Site.*

*In the June 2016 FS, EPA added sites and edited the discussion of riverbanks and groundwater in Section 1. Based upon our preliminary review, the identification and presentation of these sites contains multiple errors set forth in the attached Appendix. For example, PCBs are listed as a riverbank contaminant at Arkema, but have only been detected in a small number of samples below the applicable screening levels (with one exception for a conservative bioaccumulative SLV). Further, the June 2016 FS neglects to include a discussion of upland source controls that have been implemented and the performance of those source controls in the remedial evaluations, such as the riverbank remedial action that has been completed at the Evraz Rivergate site under DEQ oversight and with EPA concurrence. The Time Oil groundwater plume identified in section 1.2.3.4 is fully controlled and meets JSCS values for all constituents other than potentially arsenic, which does not appear to be associated with site-related groundwater contamination.*

**EPA Position:**

The conceptual site model is presented in the RI Report. The 2016 FS provides the relevant information required per EPA guidance [*Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (1988), *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (2005)]. The Respondents do not provide enough specificity as to the information absent regarding relevant Site features, baseline risks, fate and transport, and other Site uses. EPA describes contaminated media and the extent of contamination, but does not describe sources or source control in the 2016 FS Report. EPA provided a link to the DEQ source control report, which discusses in great detail the current status of source control and since that is not part of the action being taken, that level of detail did not need to be discussed in the 2016 FS. EPA's assumption in the 2016 FS was that all sources would be controlled. EPA used the information available to describe the fate and extent of the contamination in the Site.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

EPA's *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (2005) recommends that modeling be conducted at large complex sediment sites, but does not require the use of a specific model. Further, the guidance states:

These modeling efforts typically require large quantities of site-specific data. Where numerical models are used, verification, calibration, and validation typically should be performed to yield a scientifically defensible modeling study.

and

...it is important that both calibration and validation be conducted at the space and time scales associated with the questions the model must answer.

The LWG in their 2012 draft FS states:

Appendix Ha (pp 26-27): "Because somewhat limited data were collected at the beginning of the model simulation period, and because the sediment data from that time did not fully characterize sediment levels uniformly throughout the site, the entire FS sediment dataset, which includes sediment data collected between 1997 and 2010 has been deemed representative of current conditions in the site."

Appendix Ha (p 46) that is say that "assessment of temporal changes in these data is difficult because this was not and objective of the historical sediment sampling programs ... and as such, sediment data were generally examined qualitatively during model calibration."

Thus, Respondents themselves have acknowledged that the data necessary to develop a predictive model does not exists and that any model developed would have great uncertainty in predicting the outcomes of any alternative developed for the Site.

As stated above in EPA's response to LWG's issue 1q, early source control actions conducted under DEQ authority are not final CERCLA actions. The MOU puts DEQ in the lead and EPA has not approved the interim measures taken to date. Before beginning construction of the remedy, EPA will evaluate the effectiveness of source control actions conducted under DEQ authority with final cleanup objections to assess the likelihood of recontamination before taking in-river action. With respect to riverbanks identified in the ROD that are to be addressed, EPA anticipates that during remedial design that any early source control measures that have been taken will be evaluated to determine if further action under the ROD is warranted.

**LWG Dispute Issue 2b:**

*EPA's alternatives evaluation is incomplete and almost entirely qualitative. EPA's June 2016 FS does not provide quantitative long-term effectiveness estimates, provides only very limited quantitative short-term effectiveness estimates, and attempts no cost-effectiveness evaluation.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

**EPA Position:**

As discussed in the 2016 FS Section 4.1.5, long-term effectiveness and permanence refers to the expected residual risk and the ability of an alternative to maintain reliable protection of human health and the environment over time, once PRGs are achieved. Quantitative residual risk estimates are developed in the 2016 FS Appendix J Section J1 and presented in Table J1-1.

The evaluation of alternatives includes both quantitative and qualitative analysis of long-term and short-term effectiveness. The 2016 FS has provided quantitative estimates of residual risk for long-term effectiveness. The 2016 FS provides a quantitative evaluation of the remaining risks post-construction and qualitatively evaluates the time to achieve cleanup goals. The LWG provided no regulatory or guidance references that require a rigorous quantified analysis as they suggest EPA's FS should have done. EPA's *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (1988) states that the following factors are to be evaluated for short-term effectiveness:

Table 6-3. Short-Term Effectiveness

Analysis Factor	Basis for Evaluation During Detailed Analysis
Protection of community during remedial actions	! What are the risks to the community during remedial actions that must be addressed?
	! How will the risks to the community be addressed and mitigated?
	! What risks remain to the community that cannot be readily controlled?
Protection of workers during remedial actions	! What are the risks to the workers that must be addressed?
	! What risks remain to the workers that cannot be readily controlled?
	! How will the risks to the workers be addressed and mitigated?
Environmental impacts	! What environmental impacts are expected with the construction and implementation of the alternative?
	! What are the available mitigation measures to be used and what is their reliability to minimize potential impacts?
	! What are the impacts that cannot be avoided should the alternative be implemented?
Time until remedial response objectives are achieved	! How long until protection against the threats being addressed by the specific action is achieved?
	! How long until any remaining site threats will be addressed?
	! How long until remedial response objectives are achieved?

The guidance does not require the analysis be quantified. The quantitative and qualitative evaluations conducted in the 2016 FS are sufficient for an FS-level analysis.

A cost-effectiveness evaluation is not a requirement for a FS per the NCP and is not suggested in the RI/FS guidance. What is required and what was done is an individual and comparative analysis of the individual balancing criteria (long-term effectiveness and permanence, short-term effectiveness, and cost (in addition to reduction of T/M/V through treatment) that are ultimately used to make a cost-effectiveness determination. The cost-effectiveness determination is made as part of remedy identification and selection through the preferred remedy in the Proposed Plan and then the final remedy documented in the ROD (this is discussed in EPA's *The Role of Cost in the Superfund*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Remedy Selection process, EPA 540/F-96/018, Sept 1996). Thus, EPA was not remiss in not including a cost effectiveness evaluation in the 2016 FS.*

*EPA fails to explain its technical analyses, many of which appear to contain significant errors. Many of the new analyses EPA added to this FS appear to be technically incorrect and based on broad generalities, such as the surface water analysis approach included in Appendix K. This analysis appears to assume that surface water column concentrations will decrease by the same percentage as surface sediment SWACs, which ignores other inputs that will not change when sediments are remediated such as stormwater, groundwater, and upstream inputs.*

**EPA Position:**

The surface water analysis approach included in Appendix K of the 2016 FS only evaluated contaminants in sediment that exceed ARARs in the water column. The analysis assumes that the surface water in the Site will decrease by the same percentage as the sediment SWACs. This analysis was only conducted on a Site-wide scale since there was insufficient data to conduct an analysis on a smaller scale. In order to account for the relationship between Site sediment and surface water concentrations, EPA subtracted out the contribution from upriver and downtown sources in the water column in conducting this analysis; thus, did not ignore other inputs to the Site. Since EPA further assumed in the 2016 FS that all upland sources to the river would be controlled, the only remaining input to the surface water is contaminated sediment. EPA disagrees that stormwater, groundwater and upstream inputs will not change since DEQ has been working with entities to control upland and upriver sources to the Site throughout the RI/FS process and will continue these efforts post-ROD.

*Abbreviated short-term effectiveness evaluation. The June 2016 FS continues to inadequately address short-term effectiveness, particularly for an FS with alternatives that may require decades to complete. The FS makes no attempt to quantify impacts to the community, construction workers, and the environment except based on construction duration.*

**EPA Position:**

See EPA Position to UPRR's dispute issue 5.

*EPA's June 2016 FS does contain a limited evaluation of dredge release impacts. As the LWG has previously commented, guidance strongly recommends a comprehensive and quantitative evaluation of dredge release impacts. The June 2016 FS has a somewhat enhanced discussion of dredge residuals and releases, but no new quantitative evaluations were added. The June 2016 FS does not present a comprehensive and quantitative evaluation of dredging releases, the impacts on short-term effectiveness during dredging, and the associated increases in both human health and ecological risks. EPA continues to cite the findings of one project (Hudson River Phase 2) as the basis for its assumption that contaminant releases during dredging in Portland Harbor will be only 1% of the total contaminant mass dredged (as compared to the 3% recommended by*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*the LWG). EPA further uses this one project to support the concept that most of the releases greater than 1% can be eliminated by quickly covering dredge residuals, which is not fully supported. EPA implies elsewhere that residual covers should be applied on a daily basis, a requirement without precedent for a project of this scale. However, the impacts of such an approach on costs and duration of the alternatives are not quantified or further evaluated.*

*Issue 9. Dredge Releases Only Qualitatively Evaluated – EPA discusses dredge release issues in several paragraphs in Section 3 and evaluates them qualitatively in the Section 4, but neither Sections 3 nor 4 contain any quantitative assessment of potential dredge releases associated with the alternatives. Dredging releases are a well-recognized issue related to the short-term effectiveness of sediment removal that increases both human health and ecological risks. It is one of the main contributors to construction phase environmental impacts, particularly for alternatives that involve substantial dredging, such as those proposed by EPA. Per guidance (EPA 2005a), a comprehensive and quantitative evaluation of those impacts is required:*

- *“Generally, the project manager should assess all causes of resuspension and realistically predict likely contaminant releases during a dredging operation.”*
- *“To the extent possible, the project manager should estimate total dredging losses on a site-specific basis and consider them in the comparison of alternatives during the feasibility study.”*
- *“Dredging residuals have been underestimated at some sites, even when obvious complicating factors are not present.”*
- *“Project managers should be aware that most engineering measures implemented to reduce resuspension also reduce dredging efficiency. Estimates of production rates, cost, and project time frame should take these measures into account.”*
- *“The strategy for the project manager should be to minimize the resuspension levels generated by any specific dredge type, while also ensuring that the project can be implemented in a reasonable time frame.”*

*The LWG disagrees with several aspects of EPA’s limited analysis of dredge releases.*

*a. EPA uses limited qualitative evaluations of the range of release rates that can be expected for typical environmental dredging projects and the role of postresidual covers in reducing release rates. In a memorandum provided in 2013 (which are not cited in the revised FS) EPA relies on two recent projects (Lower Duwamish Boeing Plant 2 Early Action Area dredging and the Hudson River Phase 2 dredging) to support the contention that 1 percent overall releases are likely across Portland Harbor. The 1 percent release rate for the Boeing project is not supportable from the actual project data. EPA ignores the six case studies presented in Table 6.2-12 of the 2012 draft FS constructed from 2004 to 2009, all of which are based on detailed site specific data collection as summarized in the table. Thus, EPA is establishing a 1-percent release rate based on one project (Hudson River Phase 2) that appears to be one of the lowest release rates documented to date. Further, EPA is applying this optimistic release rate from a site that is entirely different both chemically and physically from the Portland Harbor Site, which includes 10 river miles of highly varying physical and chemical conditions. The 2012 draft FS provides summaries of six case studies from within the last 10 years with observed*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*average total release rates in the 3% range, and the LWG still believes this is a more realistic assumption for the revised FS. More details supporting the LWG's disagreements on this subject can be provided.*

*b. EPA describes on page 3-19 relatively detailed requirements for determining dredge completion and post-dredge sampling of the residuals, which in this particular case appears far too detailed for an FS-level discussion and does not appear to help determine the characteristics of the alternatives presented in Section 3. As described under Comment 1, EPA should leave such specific determinations to a performance-based ROD approach supported by a sitespecific engineering assessment in RD.*

**EPA Position:**

EPA's *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (2005), Section 6.5.5 "Predicting and Minimizing Sediment Resuspension and Contaminant Release and Transport During Dredging" states:

Some contaminant release and transport during dredging is inevitable and should be factored into the alternatives evaluation and planned for in the remedy design. Releases can be minimized by choice of dredging equipment, dredging less area, and/or using certain operational procedures (e.g., slowing the dredge clamshell descent just before impact with the sediment bed).

The 2016 FS explicitly states that some contaminant release is inevitable in the alternative assembly and evaluation (see Sections 3.4.8.5, 3.4.8.6, 3.4.8.10). The discussion focuses on technological and operational procedures for lessening release and resuspension.

EPA's *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (2005), Section 6.5.5 "Predicting and Minimizing Sediment Resuspension and Contaminant Release and Transport During Dredging" further states:

To compare various remedies for a site, to the extent possible, the project manager should attempt to estimate the downstream mass transport and the degree of increase (if any) in downstream surface water and surface sediment contaminant concentrations. However, at present, no fully verified empirical or predictive tools are available to quantify the predicted releases accurately.

The 2016 FS release estimate emphasizes results from Phase 2 of the Hudson River dredging because it was a recent (2011-2015), large, multi-year dredge project, with site and operational characteristics similar to the dredging proposed in the feasibility study (contaminated sediment removal in a large, riverine environment with multiple mechanical dredges using barge transport). Hudson River Phase 2 dredging operations incorporated lessons learned from Phase 1 dredging and based recommendations from the Hudson River Peer Review Panel. Thus, the project represents state-of-the-art approaches for managing dredge releases while maintaining (or increasing) productivity. The Peer Review Report states, "The repeated dredge passes and prolonged exposure of sediments

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

in the certification units (CU) resulted in increased PCB resuspension and release.” To minimize resuspension and release, the Panel recommended to improve depth of contamination estimating procedures and to:

“Establish BMPs to limit sediment resuspension and release.

Perform confirmation sampling in each 1-acre sub-CU as soon as possible after attainment of the DoC Elevation in 95 percent or more of the area is confirmed by EPA.

Place a 3-6 inch sand cover over sub-CU as soon as possible after confirmation samples are collected (before PCB analytical results are obtained).

Use PCB analytical results of composited surface samples to determine whether an area will be backfilled or capped and install final layers accordingly.”

Per these recommendations, the 2016 FS also emphasizes BMPs to limit sediment resuspension and release and placement of residual sand cover to lessen releases.

Further, on September 10, 2013, EPA provided the LWG with a memo from USACE regarding dredge residuals. [AR Doc ID # 500001131 and 500001132] EPA used this analysis and the recommendations from USACE in developing the 2016 FS.

There is nothing in the 2016 FS on page 3-19 that discusses dredge residuals; thus, EPA is unclear as to the disputed issue raised by Respondents. EPA believes that the analysis conducted in the 2016 is appropriate level of analysis necessary for this Site. EPA does not have a “performance-based ROD approach” as purported by Respondents (See EPA’s *A Guide To Preparing Superfund Proposed Plans, Records Of Decision, And Other Remedy Selection Decision Documents* (OSWER 9200.1-23P).

*EPA assumes that construction and use of sheet pile barrier walls as dredge water quality control measures based on the presence of NAPL in water depths less than 50 feet (see Appendix O) will support the short term effectiveness of all alternatives. The FS still fails to incorporate the time to install sheet pile walls in each alternative’s duration or lower production dredging within the confined space and does not evaluate the cost effectiveness of sheet piles in general. The costs EPA uses (\$2,750 per linear foot) would not be sufficient for water depths approaching 50 feet; these depths would require a much more expensive cofferdam type system. EPA also continues to show figures that depict sheet piling in greater than 50 feet of actual water depth, which is technically infeasible. (There continue to be mistakes in EPA’s mapping of the appropriate water depths.) These figures also imply that sheet piles will be installed in the navigation channel, which would infeasibly obstruct vessel traffic. Sheet pile would also impact ongoing water dependent operations and nearshore fish migration. EPA does not consider the inability to remove contaminated material within the crenulations of the*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*containment barrier and does not evaluate whether sheet piles in the navigation channel could be permitted by USACE.*

**EPA Position:**

Sheet piles are a representative engineered rigid control measure identified and evaluated for sediment dispersion control in the 2016 FS. However, that representative approach does not preclude other types of rigid control measures for consideration during remedial design. As stated in Appendix O, EPA agrees that depth can limit the use of suitable engineered options for controlling releases, and deep water depths can preclude the use of sheet piles. EPA assumes that engineered rigid containment will be utilized when NAPL was present in water depths less than 50 feet.

Engineered rigid control measures were evaluated holistically within the 2016 FS for their use in reducing or eliminating short-term releases of contaminants during construction and not on a location-specific basis. Thus, the 2016 FS does not present figures indicating design level logistical details regarding location and depth of engineered rigid control measures. Location-specific evaluations for feasibility of sheet pile versus other types of engineered rigid control measures, including placement within the navigation channel, were beyond the scope of evaluation of this 2016 FS. Details regarding sediment dispersion control and location-specific engineered rigid control measures will be determined during remedial design which is the appropriate time for those types of evaluations.

Alternative-specific costs for purchasing, installing and removing sheet pile walls are presented in Appendix G. The unit costs were developed by Anchor QEA in the draft 2012 FS on a horizontal linear foot basis. Quantities for sheet pile lengths used in the detailed alternative cost estimates and presented in the 2016 FS Appendix D Table D2.j (in horizontal linear feet) were holistically estimated for each alternative by encircling all PTW dredge and/or capped areas with silt curtains assumed for the remainder of dredged and/or capped areas.

Figure 3.4-33 of the 2016 FS presents areas of NAPL presence and Site bathymetry identifying water levels at the 50 feet MLLW. EPA acknowledges that the legend of Figure 3.4-33 should indicate that the darker shaded areas identify water depths greater than 50 feet MLLW, and the lighter shaded areas identify water depths less than 50 feet MLLW.

Remedial activities with the potential to restrict navigation in the harbor channel will be coordinated with the USACE during remedial design, including efforts to minimize sediment dispersion in areas where NAPL extends into the navigation channel. The Rivers and Harbors Act prohibits obstructions to navigation, but does not speak specifically to temporary obstructions, and CERCLA otherwise requires remedies to be protective of human health and the environment, and other federal statutes require measures to reduce impacts to ESA species or the aquatic environment as well. It was assumed in the 2016 FS that the review for compliance with the substantive requirements

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

of the relevant ARARs will occur during remedial design. However, permits and related administrative approvals, as implied by LWG, are not required for onsite CERCLA remedial actions and would not necessarily prevent implementation of these measures.

*Long-term effectiveness evaluations are qualitative and not grounded in scientific method. Rather than quantitatively evaluating long-term effectiveness (all evaluations are based on a time zero SWAC), EPA has added a new approach of evaluating alternatives using “interim targets,” which are basically ten times above the PRGs, and then EPA compares post-construction risks to these interim targets for evaluating the “overall protection of human health and the environment” for each alternative. EPA hypothesizes that if alternatives meet these interim targets, it is reasonable to assume the PRGs will be met through subsequent natural recovery in 30 years. It is confusing for EPA to claim they cannot quantitatively estimate MNR and then decide that MNR will work in 30 years. EPA also estimates “residual risk” as the estimated risk if all PRGs are met (i.e., risk at PRGs). EPA evaluated long-term effectiveness using a “magnitude of risk” defined per EPA page 4-10 as the ratio of the post construction risk to the residual risk. EPA does not explain why this analysis is technically superior to either the LWG’s effectiveness evaluations or its own prior evaluations in the August 2015 FS. Alternative I does not meet some of these interim targets, yet EPA still picks this alternative as the preferred alternative which seems logically inconsistent. Figure 4.2-6 shows that none of the alternatives even come close to the ten times PRG levels. The same is true with Figure 4.2-4 (except Alternative G) and with Figure 4.2-2 (except Alternatives F and G). These methodologies fail to evaluate remedy effectiveness on appropriate spatial scales (fish consumption and ecological exposure), they fail to assess near shore deposition, and they fail to acknowledge the time frame and feasibility of achieving PRGs given upgradient concentrations and remedial action time frames. EPA in fact states that Alternative H “achieves PRGs at the end of construction,” which is incorrect, because the very low PRGs for many COCs are not achievable through active construction.*

**EPA Position:**

Long-term effectiveness evaluation is quantitative and grounded in scientific method. Long-term effectiveness risk remaining at the site after response objectives have been met. Thus, the remaining risks are the risks from any contamination remaining on-site after PRGs are achieved. Those risks include the risks at the PRGs and the risk of exposure of any contamination that is confined in the Site. In the evaluation of long-term effectiveness, the residual risk for each RAO is provided on various spatial scales relevant to the exposure scenarios established in the BRAs. The Respondents provide no supporting documentation as to why they believe the spatial scales are inconsistent with BRAs. EPA also provided the magnitude of the post-construction risk to show how much risk was addressed through construction and how much would be addressed through MNR. EPA did not use interim targets in evaluating long-term effectiveness; interim targets were only used for the discussion of overall protectiveness. EPA established the interim targets as levels of risk that would be acceptable should RGs not be achieved in a reasonable time frame (within 30 years) and are based on uncertainty in the risk estimates. Since long-term effectiveness is conducted after the PRGs have been achieved,

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

there is no need to evaluate near shore deposition or time-frames and feasibility to achieve PRGs. These are issues discussed in short-term effectiveness. EPA appreciates the opinion of the Respondents that PRGs for many COCs are not achievable through construction, but they have not provided any scientific evidence to support their opinion.

Respondents miss the point of using the interim metrics in the 2016 FS. In the absence of a predictive model for MNR, EPA had to have a way to compare the effectiveness of the alternatives. The interim measures were not meant as absolute measures, but the closer you were to achieving them, the more likely the use of MNR would achieve PRGs in a reasonable timeframe. Figure 4.2-6 of the 2016 FS presents post-construction infant HI. As stated in Section 4.1.2 of the 2016 FS, the interim metric was ten times residual HI of 132 (or 1,320), not ten times PRG levels. This interim metric is clearly achieved by all the alternatives. Respondent is correct in their assessment of Figures 4.2-4 and 4.2-2 and EPA came to the same conclusion in Section 4.3 of the 2016 FS. These three figures all represent RAO 2, which is the fish consumption pathway, and was conducted site-wide consistent with the BHHRA. These figure do not represent residual risk for other RAOs; those are found in other figures and tables presented in Section 4 of the 2016 FS.

It is not the place of the FS to discuss why a technical analysis conducted in one FS was superior or another analysis conducted was inferior. The FS provides the technical analysis selected by EPA, whether it was developed by LWG or by EPA. EPA could not use the LWG's analysis of effectiveness in their 2012 FS for the following reasons:

PRGs are not consistent with the final baseline risk assessments

PRGs were not developed for all COCs posing risk

The residual risk evaluation uses the QEAFATE model, which EPA cited many deficiencies and did not approve

The evaluation did not calculate risk, but only compared residual sediment concentrations to PRGs

Residual risk was not quantified

Background values used were inconsistent with the 2015 dispute decision.

EPA did not select a remedy in the FS; remedy selection is conducted first in the Proposed Plan and then considering public comments and finally documented in the ROD. Therefore, the basis of EPA selecting a remedy is not a subject of this dispute.

*The Monitored Natural Recovery (MNR) evaluation is insufficient to support the alternatives evaluation. The FS continues to omit key components of an MNR evaluation as required by guidance including: 1) an adequate CSM; 2) appropriate evaluation of multiple lines of empirical evidence; and 3) a quantitative evaluation of natural recovery*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*and the associated long-term (i.e., after “time zero”) outcomes of the alternatives. New concerns with the June 2016 FS include:*

*EPA added new information on bathymetry changes and fish tissue. In Section 3.6.1.3, EPA’s updated evaluation of fish tissue concentrations over time completely ignores 2002 data without any explanation, and incorrectly evaluates data from 2007, 2011, and 2012. EPA should not combine temporally disparate data to establish baseline conditions.*

**EPA Position:**

EPA guidance *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (USEPA 2005) Section 4.4 discusses the evaluation of MNR. The key components of an MNR evaluation that the LWG claims is required by guidance is not found in this guidance document. The information LWG claims is omitted from the 2016 FS is discussed below:

- 1) An adequate CSM. The assertion that there is an inadequate CSM is both subjective and confusing. The RI, over the course of thousands of pages develops and presents the CSM. The feasibility study conducts additional analyses of the RI and other data in the context of remedial alternative development and evaluation.
- 2) Appropriate evaluation of multiple lines of empirical evidence. A full evaluation of multiple lines of empirical evidence for natural recovery is provided in Appendix D.8 of the 2016 FS.

A quantitative evaluation of natural recovery and the associated long-term (i.e., after “time zero”) outcomes of the alternatives. Outcomes greater than t=0 are not quantitatively evaluated using, for example, large, complex linked hydrodynamic, sediment transport, contaminant transport, and foodweb bioaccumulation modeling based on additional models of the effect of remediation because the results are not quantitatively accurate and absolute or relative comparisons among quantitatively inaccurate outcomes, is not helpful. Such evaluations are not “required by Guidance.” However, quantitative evaluations of empirical data (trends in sediment deposition and fish tissue concentrations), where available, were undertaken. An evaluation of temporal trends (of any media) requires consistent collection methodology over the evaluated time period. The data also need to be able to indicate the processes that are being evaluated.

The 2002 fish tissue effort collected and composited individual fish from both sides of the river. The 2007 fish tissue effort composited samples from only one side of the river; thus, it is not appropriate to compare those data to the 2002 data. While the 2002 data may be relevant for risk assessment purposes (assuming a fisherman eats fish from both sides of the river), it obscures known site/source signatures that are on one side of the river. Evaluating trends of a group of fish collected and composited from both sides of the river is counter to the CSM and what is known about the localization and transport of contamination, so the 2002 data were not further used to evaluate changes in

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

contamination. The 2011 and 2012 samples were analyzed as individuals and are not biased by the compositing issue. EPA did not “combine temporally disparate data.” EPA analyzed the data for 2007, 2011, and 2012 for changes over time to see whether a natural recovery trend in fish tissue concentrations could be discerned.

*EPA states that, “a minimum deposition rate of 2.5 cm/year was assumed as the criteria [sic] for effective MNR.” This criterion is obviously not used by EPA in the FS because the FS assumes MNR as the applicable technology for all areas outside SMAs (as opposed to applying MNR in just areas exceeding the minimum deposition rate). While deposition is a mechanism of natural recovery, there are other mechanisms occurring at this site. These mechanisms include biotic and abiotic transformations that remain unevaluated leaving the CSM incomplete. Further, the assumption of 2.5 cm/year as a criterion for natural recovery in the absence of a coherent CSM is without justification or merit. EPA has added some text that implies effectiveness is related to “mass removal” of contaminants. Page ES-15 states the advantage of Alternative H is that “it removes more contamination.” Guidance is clear that mass removal is not an appropriate way to evaluate sediment remediation alternatives; rather the evaluation must address reduction in risk.*

**EPA Position:**

EPA disagrees that the bathymetry data clearly show that net deposition occurs over large portions of the lower Willamette River during the overall multi-year period (2002 to 2009). In the LWG’s 2012 draft FS, Section 2.1.2, p.2-3 states:

Over the period from July 2003 to January 2009, the Study Area was 88 percent depositional or showed no substantial change.

EPA disagrees that areas that score neutral (no substantial change) are depositional since there is no accumulation of sediment in those areas of the Site. This line of evidence was used in the analysis of MNR in the 2016 FS (see Appendix D8), and the conclusion was that very little area of the site is depositional and the majority of the Site is neutral (transitional).

Regarding the statement “Therefore, a minimum deposition rate of 2.5 cm/year was assumed as the criteria for effective MNR.”, the referenced text is in Section 3.6.1.2 “Sediment Deposition Rate,” where the sediment deposition rate is positioned as one natural recovery line of evidence. The 2016 FS, Section 3.6.1, clearly states:

For the purposes of the FS, it is expected physical isolation through natural deposition of cleaner material and dispersion and mixing are the primary mechanisms for natural recovery at the Site.

Further, this criteria was not the only criteria used in the analysis in Appendix D8. Thus, the sentence in question should have stated:

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Therefore a deposition rate of 2.5 cm/yr was used to indicate whether areas were depositional.

The 2016 FS (p. 134) describes mechanisms of natural recovery as: “Natural recovery typically uses ongoing, naturally occurring processes to contain, destroy, or reduce the bioavailability or toxicity of contaminants in sediment. These processes may include physical (sedimentation or dispersion), biological (biodegradation), and chemical (sorption and oxidation) mechanisms that act together to reduce the risks posed by contaminants.” The CSM in the RI acknowledges that biological and chemical mechanisms occur in the Site as does the 2016 FS; thus, the CSM is complete. However, the LWG used literature values in the RI report (section 6) to discuss degradation rates. The LWG did not collect data to quantitatively evaluate these mechanisms.

The evaluation that included the 2.5 cm/year criterion was useful in further developing the CSM (which is described in the RI), concluding that:

The survey pairs range from generally erosional, to stable, to depositional between sequential survey pairs. This figure illustrates the dynamic nature of the sediment bed and the uncertainty associated with the conclusion that elevation changes between two surveys progressed evenly over time. This type of sediment bed behavior may also influence natural recovery: the process of burial would be interrupted during erosive periods, but dispersion would increase, if contaminated sediment was eroded.... This analysis indicates that most of the Site is in dynamic equilibrium where both erosion and deposition occur. In many areas of the Site, the determination of deposition and the assertion that burial is a viable long-term recovery mechanism is largely dependent on which survey pair is selected. (2016 FS p. 3-34)

The statement that “it removes more contamination” is not synonymous with the connotations regarding “mass removal.” Remedial alternatives in the FS were developed based on contaminant exposures at the sediment surface that drive risk to receptors and the alternatives were compared and evaluated on the basis of risk metrics.

The 2016 FS addressed the issues the LWG raised in their LWG List of Significant Issues with EPA’s Revised FS Sections 3 and 4 (September 8, 2015), Issue 8, pages 19-22. An analysis of MNR using multiple lines of evidence, many similar to those used by the LWG in their 2012 FS, is contained in Appendix D8 of the 2016 FS. The LWG did not provide specific concerns with Appendix D.

Further, EPA believes that the LWG’s analysis of the fish tissue data is flawed. The LWG, with assistance from CAG representative Bill Egan and other local fishermen, collected small mouth bass tissue in the lower Willamette River in the fall of 2012. The data provide a snapshot of the current levels of PCBs in tissue in the Portland Harbor area and an area upstream of the Superfund Study Area. One of the objectives of the data collection was to help EPA establish a baseline in fish tissue that can be used for comparison with future monitoring results to see if levels or trends expected from the

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

cleanup of contaminated sediments can be achieved. Fish tissue data was also collected in 2002 and 2007.

EPA's observations of these data include:

PCB concentrations in bass tissue collected in Portland Harbor remain above those that would be considered protective for people eating these fish.

While some of the results indicate that PCB concentrations have decreased compared to 2007 data, fish caught in areas of Portland Harbor that showed the highest levels of contamination previously are still well above acceptable levels. The highest levels were from fish caught in the area known as RM 11E, one of the areas with the highest levels of sediment contamination. However, the inherent degree of variability in biota concentrations preclude drawing any firm conclusions based on the limited data.

Although it is premature to draw firm conclusions, decreases in some of the tissue levels compared to the 2007 data may be attributed to improving conditions from ongoing source control work, some natural recovery from cleaner material from upstream being deposited in sediments in the lower harbor, or simply variability in the data. Future monitoring will be needed to confirm whether levels will continue to trend downward.

Although it appears that some natural recovery is taking place, EPA believes that a combination of approaches, include active cleanup methods like dredging, capping, treatment, and other methods to enhance and accelerate natural recovery, will be needed to achieve significant risk reduction for people who are eating resident fish from Portland Harbor.

EPA agrees that the results of the 2012 fish sampling displayed a general trend of lower concentrations, with the notable exceptions of RM 9W and 11E. However, the 2007 data represent composites of 5 fish collected where they were most easily caught over a river mile, while the 2012 data represents individual fish caught from specific locations. The data are not directly comparable, and two somewhat similar sampling events aren't sufficient to establish a reliable trend.

Two fish collected from RM 16 contained noticeably greater PCB concentrations than other fish collected from the reference area. Sediment data collected at RM 16 during the LWG's background study revealed that PCB concentrations in sediment an order of magnitude greater than typical concentrations measured in the background data set, indicating the presence of a possible contaminant source or hot-spot. When data from the two fish with the highest PCB concentrations are excluded from the reference area data set, data from the site displays a trend of concentrations noticeably greater than background. The areas that display the highest PCB concentrations in fish tissue are consistent with the areas where the highest concentrations were observed in the 2002 and 2007 sampling efforts, and consistent with the trend that individual, discrete areas of Portland Harbor exhibit obvious PCB contamination.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Issue 8. Discussion and Analysis of Monitored Natural Recovery Is Biased – The MNR evaluation includes text scattered across Sections 3 and 4. The overall MNR evaluation presented across these two sections is very limited and technically inappropriate in many respects. Overall, EPA suggests that MNR is potentially appropriate for the Site with many caveats and doubts expressed in that assessment. In actual fact, the case for MNR at the Site is strong given that there are multiple lines of evidence supporting the ongoing occurrence of MNR well in excess of the lines of evidence presented by EPA. The simplistic MNR analysis in Sections 3 and 4, appears to cast doubt on the validity of MNR as a potentially feasible process for the Site, which is a misleading representation of the data.*

*In Section 3, EPA presents a very simplistic MNR analysis, which generally assumes that MNR will take place outside any active remediation areas based on: 1) surface to subsurface sediment concentration ratios; and 2) a simple deposition rate calculation using two of the time series bathymetry datasets. In Section 4, EPA slightly expands upon the evaluation of MNR, including a different analysis of the time series bathymetry, a brief discussion of maintenance dredging history as an indication of deposition, and a perfunctory discussion of the 2012 smallmouth fish tissue PCB data. Generally, it is unclear why there are two separate and somewhat conflicting MNR evaluations spread across these two sections, particularly given that neither section references the other. EPA's analysis does not include the full lines of evidence strongly supporting the presence of ongoing natural recovery at the Site. The LWG has provided this information in past submittals to EPA including the 2012 draft FS, a detailed presentation of smallmouth bass fish tissue concentrations (Anchor QEA 2013), and estimated equilibrium levels for the Site (LWG 2014d, 2014g).*

**EPA Position:**

This comment pertained to EPA's 2015 draft FS, not the 2016 FS. In the 2016 FS, Section 3.6 discusses MNR and presents three lines of evidence for MNR: incoming sediment particles (sediment traps and suspended solids), sediment deposition rates (bathymetric pairs), and fish tissue concentrations (2007, 2011, and 2012 sampling events). Section 4 of the 2016 FS discusses that a fate and transport model cannot be used for this Site in Section 4.1.2 and states that the evaluation in Appendix D8 will be used to evaluate each alternative with respect to the ability for MNR to achieve cleanup goals in a reasonable time frame after construction activities are completed. Appendix D8 of the 2016 FS uses six lines of evidence to conduct this evaluation: (1) deposition and erosion rates; (2) consistence of deposition and erosion using bathymetric pairs; (3) sediment grain size; (4) anthropogenic factors; (5) surface to subsurface sediment concentration ratios; and (6) wind and wake generated waves.

*In summary, the lines of evidence for ongoing natural recovery at the Site are:*

- *Sources are being progressively controlled. DEQ's latest source control report (DEQ 2014) indicates DEQ has completed source control evaluations and implemented (or will implement) controls on one or more potential pathways at approximately 119 of 168 sites examined in detail to date.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

**EPA Position:**

While it is important that sources of contamination are controlled at the Site to ensure MNR will be effective, controlling sources is not a line of evidence that MNR is occurring in various areas of the Site.

- *The aggregate information from five multi-beam surveys indicates widespread deposition of sediments across many areas of the Site. Although EPA emphasizes the uncertainties of the data, for reasons detailed below, the LWG disagrees these data present substantial uncertainties about deposition.*

**EPA Position:**

See EPA's position on p. II-54.

- *Sediment trap and suspended sediment data clearly show that incoming settling sediment has substantially lower contaminant concentrations than most of the Site bedded sediment, which will drive bedded sediment concentrations lower over time.*

**EPA Position:**

EPA agrees and included this line of evidence in the 2016 FS, Section 3.6.1.1.

- *Radio-isotope coring data, although limited, indicates deposition rates consistent with other measures such as the bathymetry time series.*

**EPA Position:**

The LWG conducted radioisotope sampling on 4 cores to a depth of 90 cm and analyzed for <sup>7</sup>Be, <sup>137</sup>Cs, and <sup>210</sup>Pb. The results are presented in the *Draft Monitored Natural Recovery (MNR) Technical Memorandum – Step 2 Data Evaluation Methods* provided in Appendix A5 of the final RI Report. The report provides the following information: The <sup>7</sup>Be activities were undetectable at every station except one and detectable concentrations were only in the upper 5 cm.

The <sup>210</sup>Pb profiles at the sampled stations did not show the exponential decay profile normally exhibited in a quiescent depositional environment. Evaluation of the data indicates that although no apparent decay trends exist for stations NA-3 and NA-4, stations NA-1 and NA-2 showed a general decay trend with depth. The downward trends in <sup>210</sup>Pb concentrations in two cores and the generally low <sup>210</sup>Pb concentrations in all cores suggest a much more dynamic sedimentation environment than assumed by simple application of the CRC or CIC models. Such profiles are indicative of sediment systems that have large amounts of gross sedimentation and gross resuspension.

Stations NA-2, 3, and 4 showed peak <sup>137</sup>Cs activities (0.13 to 0.37 pCi/g) within the top 5 cm of the cores and attained an approximate baseline activity at 0.05 pCi/g at deeper depths. Station NA-1 showed a consistent activity matching the baseline activity (0.05 pCi/g). In environments where the assumptions of the CRM and CIC Models are

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

accurate, these peaks are highly correlated with the peak in nuclear arms testing in 1963. Therefore, under these assumptions, the exposed surface sediment layer is indicative of the 1963 surface.

Based on this information, EPA disagrees that the radioisotope cores indicate any useful information regarding deposition rates.

- *Site surface sediment grain sizes are fine-grained across the majority of the Site, strongly indicating a long term depositional environment exists in these areas.*

**EPA Position:**

While EPA agrees that sediment grain size is a useful line of evidence and used that information in the 2016 FS, Appendix D8, EPA disagrees that only surface sediment grain size should be used and that the majority of the Site has fine grain size (see 2016 FS, Figure 2.2-1).

- *Surface to subsurface sediment concentration ratios in most areas of the Site indicate newer surface strata contain lower concentrations than older subsurface strata, which illustrates that surface sediment concentrations are decreasing over time.*

**EPA Position:**

EPA agrees and included this line of evidence in the 2016 FS, Appendix D8.

- *Surface sediment concentrations measured over time (i.e., time series) indicate surface sediments have decreasing contaminant concentrations. The 2012 draft FS data are somewhat limited, but new PCB data collected in 2014 by other parties may provide additional useful information for this line of evidence.*

**EPA Position:**

While EPA agrees that sediment time-series data would be useful in establishing MNR trends, no such data exists. The 2014 data that the Respondent refers to was not conducted in manner statistically comparable to the baseline data set and cannot be used to establish a trend. Further, many more years of information need to be collected to understand the MNR trends in sediment as they fluctuate from year-to-year. Further, the quality of the data collected in 2014 is questionable since it was not conducted under an EPA approved QAPP or work plan.

- *Smallmouth bass PCB tissue measurements made in 2002, 2007, and 2012 indicate statistically significant declines in tissue concentrations across almost all areas of the Site (Anchor QEA 2013). Differences in sampling and compositing schemes across the years can be controlled to determine statistically valid results.*

**EPA Position:**

While EPA agrees that the smallmouth bass PCB tissue concentrations from 2007, 2011 and 2012 indicate some information about MNR at the Site, there is insufficient data to

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

statistically compare this data. [AR Doc # 100033469] EPA does not believe that the 2002 data set can be compared to these other data sets (see EPA positions on p. II-52 and II-54 and EPA position to LSS Issue 5).

• *Comparisons of sediment profile images collected in 2001 (by the LWG) and 2013 (by other parties) indicate that much of the Site now has well established Stage 3 benthic communities indicative of stable and recovering substrates.*

**EPA Position:**

Stage III populations are late successional stage populations, meaning that the benthos has had some time to recolonize a disturbed area (or have not been disturbed), have the greatest number of species, and have species that burrow and feed as deep in the sediment as site conditions permit. Benthic populations in river miles 7.0 to 9.7 and 3.0 to 5.1 were mostly classified as Stage III populations in the 2002 SPI survey. The 2002 SPI survey did not include areas between RM 1.9 and RM 3.0 or between RM 9.7 and RM 11.8. Therefore, it would be hard to make a case that the health of benthic populations has substantially improved between 2002 and 2013, based solely on SPI data. The Respondent does not provide the comparison of the areas they believe have established Stage III populations where they did not exist before. Further, the 2013 SPI survey collected by other parties was not conducted under an EPA approved work plan or QAPP and EPA is concerned about representativeness of information.

• *Simple modeling (such as EPA's SEDCAM modeling, which was not provided in Section 3 or 4) and complex modeling (such as the 2012 draft FS QEA FATE model and coupled dynamic Food Web Model) all generally indicate recovery of surface sediments over a reasonable timeframe toward a relatively consistent range of potential equilibrium levels.*

**EPA Position:**

There are no models available to predict MNR for the Portland Harbor Site. As stated in the 2016 FS, Section 4.1.2, EPA reviewed the predictability of the 2012 draft FS QEA Fate Model and found its predictability poor. EPA also did not use the SEDCAM model as it only predicts deposition, not erosion, and is thus inconsistent with the conceptual site model.

*Specific issues relevant to the EPA Section 3 and 4 MNR evaluations include:*

*a. In Section 3, EPA's MNR text starts by discussing that MNR is not usually selected as a "stand-alone" technology per guidance. Although this is consistent with guidance, neither the LWG nor EPA proposes to use MNR as a stand-alone remedy. The Section 3 text then goes on to list a series of cautions and conditions about MNR in bullet points, apparently intended to support the opening contention that MNR is not a good stand-alone remedy.*

*Further, some of the conditions noted in the bullet points as conducive to natural recovery are actually present or strongly indicated in Portland Harbor. Therefore, the purpose of this discussion in light of EPA's selection of MNR as a component of all*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*alternatives is unclear and should not be relied upon to undermine the substantial evidence supporting MNR as a major component of the overall remedy.*

**EPA Position:**

This information is presented to inform the reader of the information needed to select MNR as a viable technology. EPA then goes on to discuss how Site-specific information was considered and MNR technology is viable at the Site. EPA disagrees that the information presented undermines the selection of MNR at the Site.

*b. EPA's Section 3 discussion of surface to subsurface sediment chemical concentration ratios within the Site is misleading. For example, EPA uses a surface to subsurface ratio of 0.5 (which is more conservative) to indicate likely MNR, whereas the 2012 draft FS uses a ratio of 0.67. EPA does not discuss the rationale for the selection of this more conservative ratio, or why it leads to any more valid conclusions about natural recovery at the Site.*

**EPA Position:**

The 2016 discusses surface to subsurface sediment concentration ratios in Appendix D8, not in Section 3. A subsurface-to-surface ratio of 2 and 10 were both used in the evaluation. The Respondent does not provide why they believe that using a ratio of 0.67 (or 1.5 subsurface-to-surface ratio) is more appropriate than the evaluation provided in the 2016 FS. At lower contaminant concentrations, it is very difficult to discern with any confidence the difference between a ratio of 1.5 or 2. For this reason, EPA added the evaluation using a ratio of 10. EPA did not use the LWG's ratio of 1.5. This number is based on site-wide averages of surface and subsurface data and then compared to obtain a ratio, which was 1.5. While this information provides a general depiction of the site as a whole, EPA was interested in whether MNR was viable in particular areas of the Site. A ratio of 1.5 is too small to discern whether or not MNR is working in areas with lower contaminant concentrations, which is where EPA intended to use the technology.

*c. EPA's Section 3 discussion of deposition rates within the Site is misleading. EPA appears to have ignored the LWG's comments in October 2014 where the LWG described differences in the definition of areas that are "reliably depositional." EPA continues to use the "typical bathymetric survey measurement error" of 6 inches or 15 cm (which equates to 2.5 cm per year (cm/yr) over the period of 2002 to 2009) to define areas that are reliably depositional. Measurement error in a bathymetric survey is a random error (i.e., there is no bias) with an average value of 0 cm for many measurements.*

*These data are normally distributed, so that a 15-cm measurement error is a very rare occurrence (e.g., at the 3-sigma level, which has a probability of occurrence of less than 1% for a single measurement). Thus, EPA's use of a +15-cm measurement error at a single location (10-foot grid) to specify the 2.5 cm/yr deposition threshold is extremely conservative. Further, evaluating and interpreting bed elevation changes on a 10-foot grid is not appropriate due to inherent measurement uncertainty at this small spatial scale. Averaging bathymetry data over larger spatial scales provides a more reliable*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*method for analyzing bed elevation changes because the effects of measurement error on the results decrease as the spatial scale increases. This approach was used by LWG in the 2012 draft FS to analyze bed elevation changes over a wide range of spatial scales in the Lower Willamette River.*

*The uncertainty in EPA's analysis results can be significantly reduced simply by averaging the bathymetry data over slightly larger spatial scales. For example:*

*i. Using a 20-foot grid (i.e., averaging of four data points from the 10-foot grid) would reduce the measurement uncertainty by a factor of 2 (i.e., +7.5 cm), which would reduce the deposition threshold to 1.25 cm/yr.*

*ii. Using a 30-foot grid (i.e., averaging of nine data points from the 10-foot grid) would reduce the measurement uncertainty by approximately a factor of 3 (i.e., +5 cm), which would reduce the deposition threshold to about 1 cm/yr.*

*Thus, using the data over appropriate spatial scales, it can be reliably determined that areas experiencing more than 7.5 cm of deposition over the 6-year period between 2003 and 2009 are depositional (equating to 1.25 cm/yr).*

*This difference between EPA and LWG's approach results in a large change in the amount of Site area characterized as reliably depositional (the LWG method results in 63%; the EPA method results in 47%).*

**EPA Position:**

Appendix La of the 2012 Draft FS (p. 37) states that the typical survey measurement error range is 0.5 feet, resulting in an uncertainty range of 1 foot for bed elevation changes between two surveys. The uncertainty range in one direction (i.e., depositional) would be 6 inches, which equates to roughly 1 inch (2.5 cm) per year for the period between the 5/2003 and 1/2009 surveys. Therefore, the depositional criterion EPA is using assesses deposition that can reliably be detected using the available survey data. This information was provided to the LWG in a meeting on June 5, 2014, and again in an email on October 21, 2016. [AR Doc # 100010336]

There is an engineering "rule of thumb" that "When measurements add, their errors (uncertainty) add. When measurements multiply their relative errors add." In order to average a series of values, the values are first summed and then the sum is divided by the number of values. When there is error associated with the values, the error of the average value is derived using the same formula: the error associated with each value in the series is summed and then the sum of the error is divided by the number of values. The Respondents neglected to sum the error with each value and thus erroneously concluded that somehow averaging the area over larger footprints would lessen the error. However, averaging errors does not reduce the error in the measurement and, thus, the error is still the same for the average. Consequently, averaging over larger grids does not affect the uncertainty in the measurement.

*d. In Section 4, EPA uses a different approach that biases results when evaluating temporal changes in bathymetry data between 2002 and 2009 and is inconsistent with recent Sediment Erosion and Deposition Assessment (SEDA) guidance (Hayter et al. 2014). EPA concluded that "many areas of the site are in dynamic equilibrium" and "for*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*many areas of the site, the determination of deposition, and the assertion that burial is a viable long-term recovery mechanism, is highly dependent on which survey pair is selected.”*

*Generally, temporal changes in the Lower Willamette River (LWR) bathymetry (and similar river systems) are dynamic, with alternating periods of gross deposition and erosion occurring in localized areas. The bathymetry data clearly show that net deposition occurs over large portions of the LWR during the overall multi-year period (e.g., 2002 to 2009) examined as discussed in Comment 8c above. The net deposition process during a multiyear period does not typically correspond to steady continuous deposition; net deposition is due to a cumulative increase in bed elevation that results from alternating periods of deposition and erosion, with gross deposition being greater than gross erosion over a long period. This is not a surprising or unusual finding for this or similar river systems. Consequently, EPA’s emphasis on comparisons between various individual pairs of bathymetry surveys ignores the overall trends represented by the bathymetry series as a whole. The FS is also misleading regarding the uncertainty of this information, given these dynamic sedimentation processes are routinely evaluated at sediment remediation sites using time series bathymetry data.*

*Such routine methods are used in the 2012 draft FS and are consistent with the most recent guidance (Hayter et al. 2014). EPA does not reference this guidance in the Section 3 or 4 bathymetry discussions.*

**EPA Position:**

In the 2016 FS, Appendix D8, EPA uses the comparison between the January 2002 and January 2009 bathymetry surveys as one line of evidence for MNR and a comparison between each of the bathymetry surveys as another line of evidence. The first gives an overall understanding of deposition and erosion in the long-term. As stated by the Respondent, temporal changes in the Lower Willamette River (LWR) bathymetry (and similar river systems) are dynamic, with alternating periods of gross deposition and erosion. Thus, comparing all the bathymetric pairs provides information regarding where there is consistent deposition or erosion and where there is alternating deposition and erosion.

*e. In Section 4, EPA devotes one paragraph to a discussion of the 2012 smallmouth bass tissue PCB data. EPA indicates that an “exact comparison” between 2002, 2007, and 2012 smallmouth bass tissue data is not possible because the “sampling and compositing schemes vary between years.” The LWG provided a detailed presentation to EPA in March of 2013 comparing the tissue data across these years, including several types of statistical tests and other trend comparisons (Anchor QEA 2013). That LWG presentation showed that, in many respects, the differences in sampling and compositing across sample years can be controlled to obtain statistically meaningful information regarding clear declines in fish tissue PCB concentrations. EPA included in Section 4 the single most simplistic graph from the start of the LWG’s presentation, which was intended to merely summarize the data that are available, not demonstrate observed declines. EPA concludes from this one misused graph that the data are only “suggestive of declines.” The text ignores all of the other detailed information and graphs available that more*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*clearly show the tissue PCB declines, and EPA ignores all of the statistical analysis provided by the LWG. Consequently, EPA substantially understates the role of these data as a strong line of evidence for the effectiveness of MNR at the Site.*

**EPA Position:**

See EPA Position on p. II-54.

**LWG Dispute Issue 2c:**

*EPA's PTW approach is inconsistent with guidance and fails to result in reduction in toxicity, mobility or volume of hazardous substances commensurate with its extraordinary projected cost. As discussed in detail in the LWG's prior comments, EPA has designated as PTW large geographic areas with relatively low concentrations of contaminants of concern based primarily on its evaluation of the human health fish consumption criteria, which is an exposure pathway not based on highly toxic criteria and not typically used for PTW "highly toxic" designations. The conclusion that this exposure pathway should not be the basis for a PTW designation is corroborated by 2012 fish tissue data, previously shared with EPA, that show PCB concentrations in fish tissue have declined significantly resulting in human health risks that are likely to be lower than 10-3. The FS fails to satisfactorily explain how sediments in these large areas are highly mobile or highly toxic and cannot reliably be contained in place. For example, the FS does not explain or justify why sediment at the relatively low concentration of 200 ppb PCBs is "highly toxic," which is generally defined as a concentration several orders of magnitude above levels that allow for unrestricted use and unlimited exposure. At many other large sediment sites around the country, EPA's cleanup level for total PCBs is 1 part per million. The level requiring special disposal under TSCA is 50 ppm (50,000 ppb). Sediment at 200 ppb PCBs is well below what is considered an acceptable cleanup level at these other sites. And, as discussed above, EPA's recalculated site-wide PCB SWAC of 208 for Alternative A (No Action) used in Table J2.3-1a of Appendix J for the residual risk assessment exceeds this arbitrary PTW threshold, undermining the usefulness of the concept as a balancing criteria or otherwise.*

*The June 2016 FS includes new explanations that further show that EPA's PTW approach is inconsistent with guidance and flawed. For example, EPA states, "'Reliably contained' was not used in identifying PTW but rather was used to determine what concentrations of PTW could be reliably contained." This clearly contradicts the guidance, which discusses "reliably contained" as part of PTW identification.*

*EPA should not identify materials that can be reliably contained as "principal threat waste." EPA admits (in Table 3.2-2) that all COCs at the concentrations present in the site, with just two exceptions-- chlorobenzene and naphthalene, can be reliably contained. Thus, none of the areas where these contaminants are absent should be designated as PTW. Blanket identification of large areas of relatively low concentration sediments as PTW is neither required by the NCP nor necessary to protect public health or the environment.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Similarly, the June 2016 FS provides no discussion or explanation of how material with sediment concentrations above the EPA-identified “highly toxic” thresholds or the presence of “globules or blebs” of Non-Aqueous Phase Liquid (NAPL) pose risk of contaminant migration. Further, EPA’s PTW-NRC footprint is mapped very differently in the FS and Proposed Plan, showing that, even at this late date, EPA has not spent adequate time evaluating this issue.*

*46 See, e.g., LWG List of Significant Issues with EPA’s Revised FS Sections 3 and 4 (September 8, 2015), Issue 2 and page 8.*

*Issue 2 Principal Threat Waste – The LWG previously commented (LWG 2014c) that a precise identification and highly quantitative evaluation of PTW at the Site is not necessary or productive for completing the revised FS and is not necessary for EPA’s selection of a remedial alternative. Per those past comments, EPA’s proposed PTW approach is inconsistent with guidance on PTW (EPA 1991) in several respects. The LWG disagrees with EPA’s logic and approach for determining PTW.*

*First, EPA uses fish consumption scenarios to determine “direct” cancer risk highly toxic thresholds in excess of 10<sup>-3</sup>. Before applying such thresholds for PTW identification, the presence of actual risks greater than 10<sup>-3</sup> needs to be determined. In fact, greater than 10<sup>-3</sup> risk was not found in the EPA-approved Baseline Human Health Risk Assessment (BHHRA) for dioxin/furan TEQ, total DDx, or BaPEq for any scenario evaluated.*

*Therefore, the definition of highly toxic as described by EPA (1991) is only potentially applicable to total PCBs. Second, as described in LWG’s past PTW comments (LWG 2014c) greater than 10<sup>-3</sup> cancer risk was found for PCBs in the BHHRA for three fish consumption scenarios: subsistence (mixed diet, fillet), recreational (mixed diet, fillet), and tribal (whole body and fillet). But EPA guidance (1991) describes PTW materials as a source for “direct exposure.” The fish consumption pathways are, by definition, indirect pathways from sediment through fish to people, and these pathways do not represent “direct” exposures from sediment contaminants as described in the guidance. See the LWG’s 2014 PTW comments for more details on this issue (LWG 2014c).*

*Third, the point-by-point application of EPA’s highly toxic thresholds is entirely inconsistent with the spatial and temporal scales associated with this indirect exposure as described in the BHHRA. This includes that people catch fish over multiple areas and fishing events and that the fish range across different areas during those timeframes.*

*Fourth, EPA uses inapplicable and inferential evidence to identify potentially highly mobile (i.e., NAPL) material in a manner that is inconsistent with the intent of the PTW guidance. The highly mobile aspect of the PTW definition should be applied for NAPL consistent with situations described in the guidance (EPA 1991), such as “pools of NAPLs submerged beneath ground water or in fractured bedrock, NAPLs floating on ground water” or where physical processes are likely to mobilize “source materials” as defined in the guidance. EPA’s identification of any potential NAPL as PTW is inappropriate and inconsistent with the guidance. For example, EPA identifies solid tar materials at Gasco as analogous to highly mobile liquids, which the guidance defines as “liquids and other highly mobile materials (e.g., solvents).” Also, at the Arkema Site,*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*continuous cores have been visually logged and hundreds of samples have been analyzed at the laboratory and, to date, no chlorobenzene NAPL has been found in Arkema sediments. EPA also uses any visual trace observations of NAPL, such as “blebs and globules,” to identify highly mobile PTW. This approach is clearly inconsistent with the terms used in the guidance, such as “pools of NAPLs” as quoted above. See LWG 2014c for more description of how EPA’s highly mobile PTW approach is inconsistent with the PTW guidance.*

*Also, EPA’s PTW approach is inconsistent with the approach taken at other large river sediment remediation sites, including EPA’s recent Region 10 ROD for the Lower Duwamish Waterway, where the maximum sediment PCB concentration was 220 mg/kg. Nonetheless, EPA determined the Duwamish sediments are generally “low-level threat waste” (EPA 2013). In comparison, at Portland Harbor, the maximum PCB concentration is 36 mg/kg, and EPA is identifying concentrations of 0.2 mg/kg as PTW. The LWG’s PTW comments (LWG 2014c) review the PTW approach at five other large sediments sites, mostly with much higher contaminant levels than Portland Harbor. All of those sites also do not identify specific PTW areas in the FS process.*

*Additional specific issues related to the PTW text in Section 3 include:*

*a. EPA defines areas as PTW without including the reliably contained step of the evaluation described in the NCP and guidance (EPA 1991). Without the reliably contained evaluation included, these areas cannot be appropriately defined as PTW. In other words, only the areas that EPA designates as “not reliably contained PTW” have the potential to actually be defined as PTW.*

*See NCP Preamble, 55 FR 8666 at 8703 (March 8, 1990): “Principal threats are characterized as waste that cannot be reliably controlled in place, such as liquids, highly mobile materials (e.g., solvents), and high concentrations of toxic compounds (e.g., several orders of magnitude above levels that allow for unrestricted use and unlimited exposure).”*

*b. EPA’s not reliably contained analysis using the so called “super cap” approach is also technically incorrect. EPA uses generalized Site-wide groundwater seepage rates for the super cap analysis rather than more localized estimates available in the RI. Further, groundwater control systems exist at both Gasco and Arkema sites, which EPA states were not considered in the analysis. For example, at the Gasco site, the groundwater source control system has been shown to cause negative seepage (i.e., movement of river water down into the sediment bed) over broad areas of the offshore sediments, but EPA’s super cap analysis assumes that positive groundwater seepage out into the river is still occurring. Using appropriate seepage parameters where groundwater source control systems exist would result in no identification of not reliably contained material at the Gasco site. A similar analysis is appropriate for sediments offshore of the Arkema site, which has installed a slurry wall and a groundwater extraction and treatment system designed to prevent migration from the uplands to the river. EPA should consider the specifics of that groundwater control system, as well as other areas with significantly lower than average groundwater gradients (e.g., RM 2-4 East).*

*c. EPA’s PTW approach results in large relatively low concentration areas of the Site being identified as PTW. For example, large PTW areas exist outside much of the SMA footprint of the smaller alternatives (e.g., Alternatives B and C), which is a unique*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*circumstance for a sediment FS as far as we are aware. Further, the concentrations that EPA is proposing as PTW would be considered completely safe under other common remedial and regulatory scenarios. For example, EPA's PTW level for PCBs of 200 µg/kg is below EPA's Regional Screening Levels (RSL) for residential soil, which range from 230 to 3900 µg/kg (per EPA's June 2015 RSL residential soil table carcinogenic risk values for total PCBs). DEQ's risk-based residential soil cleanup standard for PCBs is 200 µg/kg. Although EPA indicates that PTW is only a "preference" for treatment, EPA's decision trees indicate that PTW is almost always subject to treatment including reactive armored caps, reactive residual cover layers after PTW is removed, in situ treatment, or ex situ treatment after removal and before disposal. Regarding ex situ treatment, EPA determines that any PTW that is based on NAPL (including trace observations per above) and PTW related to cPAHs or DDx must be ex situ treated. Essentially, the only situation where removed PTW does not need to be ex situ treated is for high concentration materials above the PCBs and dioxin/furan PTW thresholds. EPA's PTW approach contributes substantial ex situ and in situ treatment components to both removal and in-place technologies for all alternatives both inside and outside of SMAs, as well as extensive sheetpiles (and associated costs) for removal in some areas. For example, Alternative B involves ex situ treatment of 240,840 to 321,120 cubic yards (cy) of sediment, which is about 39% of the total volume removed under this alternative.<sup>4</sup> (Although EPA orally indicated on August 27 that much of this volume is due to RCRA hazardous waste determinations, this is not verifiable based on review of the information contained in EPA's cost appendix. See Comment 18 for more comments on RCRA hazardous waste determinations.) Per above, the PTW guidance does not support the need for treatment for all the materials falling within EPA's wide definition of PTW for this Site.*

*d. EPA is using extremely low dioxin/furan PRGs for PTW determinations that the LWG has previously commented are technically incorrect and not reflective of actual baseline risks (LWG 2014d, 2015a, 2015b). Also, as noted above for PCBs, EPA's dioxin and furan PTW levels are extremely low as compared to other common regulatory programs. For example, EPA's TCDD PTW level is 10 ng/kg in Table 3.2-1, while EPA's soil remedial goal for residential areas is 50 ng/kg.<sup>5</sup>*

*e. From a purely engineering perspective, it is not necessary to conduct ex situ treatment of EPA-identified PTW before disposing of this material in a permitted landfill. The landfill acceptability criteria EPA discusses in Section 3 indicate that most of the PTW (as defined by EPA) would be reliably contained at the landfill without need for prior ex situ treatment (not just PCB and dioxin/furan PTW).*

**EPA Position:**

The comment appears to be about both identification of PTW and the statutory requirement that remedies be cost effective.

**Identification of PTW:**

The NCP states that EPA expects to use treatment to address the principal threats posed by a site, whenever practicable" and "engineering controls, such as containment, for waste that poses a relatively low long-term threat." [40 CFR Section 300.430(a)(1)(iii).]

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

As noted in *A Guide to Principal Threat and Low- Level Threat Wastes* (Superfund Publication 9380.06FS, November 1991):

Principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. They include liquids and other highly mobile materials (e.g., solvents) or materials having high concentrations of toxic compound.

Therefore, principal threat wastes are either highly toxic **OR** they are highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur.

Highly toxic principal threat waste at Portland Harbor was identified based on a  $10^{-3}$  risk for an individual contaminant which is three orders of magnitude greater than EPA's point of departure for acceptable risk [see NCP 40 CFR Section 300.430(a)(1)(iii)] and with the Oregon State residual risk ARAR of  $10^{-6}$  for individual contaminants and an order of magnitude greater than EPA's upper risk range for cumulative carcinogenic risks. Contaminants with concentration in the Site determined to be highly toxic include PCBs, cPAHs, DDx, and dioxins/furans (2,3,7,8-TCDD, 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, and 1,2,3,4,6,7,8-HxCDF).

EPA disagrees with the Respondents that current Site risks, based on recent fish tissue samples it conducted, are likely less than  $10^{-3}$ . That statement is speculative and not supported beyond the LWG's own interpretation of the fish tissue data, which is based solely on one fish species (smallmouth bass) and one contaminant (PCBs) and the selected fish species sampled was the third least contaminated species of all fish sampled during the RI. Whereas, the BHHRA evaluated risk from fish consumption based on four fish species.

Highly mobile principal threat waste at Portland Harbor was defined as NAPL that generally cannot be reliably contained **OR** would present a significant risk to human health or the environment should exposure occur. NAPL generally releases contaminants into the groundwater or surface water and cannot be reliably contained and poses significant risk to human health or the environment. EPA evaluated two sources of NAPL, MGP waste offshore of NW Natural and chlorobenzene offshore of Arkema. These NAPL sources release benzo(a)pyrene and naphthalene (MGP waste), and DDT (Arkema) to groundwater and pore water. EPA clearly stated in the 2016 FS that the chlorobenzene dissolves the DDT and makes it bioavailable – the BERA concluded dissolved phase DDx in pore water (TZW) had an HQ of 210. Benzo(a)pyrene (a PAH) and DDT have been identified in the BERA as having contaminants of ecological significance and naphthalene and chlorobenzene have HQs of 1,100 and 190, respectively. EPA conducted an evaluation of benzo(a)pyrene, naphthalene, chlorobenzene, PCBs and DDT to determine if they were reliably contained. DDT (not comingled with

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

chlorobenzene) and PCBs were determined to be reliably containable at all concentrations. Benzo(a)pyrene at concentrations greater than 140,000 µg/kg, and naphthalene and chlorobenzene at any concentration was determined to not be reliably containable. Therefore, the MGP waste and the chlorobenzene are both highly mobile principal threat waste. While modeling may potentially be an indicator of potential performance in some situations, it is not deterministic that the waste will actually be contained in the given situation.

“Reliably contained” alone was not used in identifying principal threat waste since that was not a requirement of the NCP nor EPA guidance *A Guide to Principal Threat and Low- Level Threat Wastes*. Further, there is no requirement that highly toxic source material be reliably contained. However, Highlight 3 in *A Guide to Principal Threat and Low- Level Threat Wastes* provides an example of mobile source material as:

Mobile source material - surface soil or subsurface soil containing high concentrations of contaminants of concern that are (or potentially are) mobile due to wind entrainment, volatilization (e.g., VOCs), surface runoff, or sub-surface transport.

EPA evaluated whether surface or subsurface sediment containing high concentrations of contaminants of concern are (or potentially are) mobile due to river currents, volatilization, wind/wake wave action or partitioning to pore water or surface water. In other words, any sediments with high concentrations of contaminants that are found in other media (surface water, pore water, biota) that are transported through various environmental mechanisms is a mobile source material. Consequently, the highly toxic principal threat wastes could also be deemed highly mobile source material. However, many of these contaminants (PCBs, DDT not comingled with chlorobenzene, and dioxins/furans) can be reliably contained (as discussed above) and thus were not identified as highly mobile source material.

EPA’s evaluation of principal threat waste is consistent with the exposure assumptions at this Site. Highlight 2 in *A Guide to Principal Threat and Low- Level Threat Wastes* identifies contaminated sediment as source material, so the media of which is source material is the contaminated sediment. Further, on p.2 of EPA’s *A Guide to Principal Threat and Low- Level Threat Wastes* it states:

Determinations as to whether a source material is a principal or low level threat waste should be based on the inherent toxicity as well as a consideration of the physical state of the material (e.g., liquid), the potential mobility of the wastes in the particular environmental setting, and the lability and degradation products of the material. However, this concept of principal and low level threat waste should not necessarily be equated with the risks posed by site contaminants via various exposure pathways. Although the characterization of some material as principal or low level threats takes into account toxicity (and is thus related to degree of risk posed assuming exposure occurs), characterizing a waste as a principal threat does not mean that the waste poses the primary risk at the site.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

As an example of this, EPA's *A Guide to Principal Threat and Low- Level Threat Wastes* on p.2 provides:

For example, buried drums leaking solvents into ground water would be considered a principal threat waste, yet the primary risk at the site (assuming little or no direct contact threat) could be ingestion of contaminated ground water, which as discussed above is not considered to be a source material, and thus would not be categorized as a principal threat.

A similar scenario was used at Portland Harbor where the contaminated sediment are releasing contamination into surface water and biota is a principal threat waste even though the primary risk at the site (assuming little or no direct contact threat) is consumption of contaminated fish. EPA would argue that the contamination in the fish itself is not a principal threat waste (similar to groundwater in the example above), but the contamination in the sediment is akin to the leaking drum that is the source material.

Identification of PTW is site-specific based on risk from exposure at the Site. All principal threat waste decisions are site-specific. As stated in EPA's *A Guide to Principal Threat and Low- Level Threat Wastes*:

Although remedy selection decisions are ultimately site-specific determinations based on an analysis of remedial alternatives using the nine evaluation criteria, these expectations help to streamline and focus the remedial investigation/feasibility study (RI/FS) on appropriate waste management options.

Thus, EPA only used site-specific information to identify principal threat waste and determine waste disposal options (including treatment) at this site.

Identification of principal threat waste and source material is not based on a site-wide average since EPA is not designating the entire Site as containing principal threat waste. Consistent with EPA guidance, principal threat waste is high concentration areas of contamination. Those high concentration areas are identified as samples that exceed the threshold for principal threat waste. For highly toxic contaminants, those concentrations are provided in Table 3.2-1, and comprise 145 acres of the Site (less than 7 percent of the Site). The 2016 FS evaluation complied with the NCP expectation that treatment be used to address the principal threats posed by the Site, wherever practicable (40 CFR §300.430). However, based on the technology assignment process in the 2016 FS, if sediment classified as containing PTW was located in an area designated for capping, then there was an assumption that a reactive cap will be assumed for that area to meet the preference for treatment. The exact presence, location, and treatment requirements (ex-situ or in-situ) of principal threat waste will be determined in remedial design consistent with requirements in the ROD. EPA used the information currently available to base the cost evaluation for treatment of principal threat waste in the 2016 FS.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Furthermore, we strenuously disagree with the LWG's argument that any PCB contaminated sediment under 50 ppm should not be identified as highly toxic PTW because that is TSCA's regulatory threshold for disposal of electrical equipment or other PCB-containing materials. Such an argument inappropriately equates two different statutes, one primarily regulatory (TSCA) and one fully remedial. The LWG's view ignores the statutory mandate of CERCLA to select remedies for releases of or threats of releases of hazardous substances that present unacceptable risk to human health or the environment and the NCP's requirement to address principal threats at a site.

Cost Effectiveness:

The issue of cost effectiveness is tied directly to the CERCLA statutory requirement under Section 121(b) (1) that: "The President shall select a remedial action that is protective of human health and the environment, that is cost effective, and that utilizes permanent solutions and alternative treatment ... to the maximum extent practicable."

EPA did not select a remedy in the 2016 FS and therefore this statutory requirement is not applicable to the 2016 FS and is not subject to the dispute provisions in the AOC.

**LWG Dispute Issue 2d:**

*Remediation waste management components of EPA's alternatives are difficult to understand, appear in many cases to be inappropriate or inconsistent with existing requirements, and seem likely to add significant cost without contributing any additional risk reduction benefit. EPA's June 2016 FS no longer includes the disposal decision tree found in the August 2015 FS. Although that decision tree contained multiple errors and inconsistencies, the absence of any such tool in the June 2016 FS makes it difficult to determine EPA's disposal assumptions for FS purposes (or the Proposed Plan). New EPA text in the June 2016 FS makes a few broad statements that could have major impacts on cost. For example, on Page 3-28, EPA notes that all detectable concentrations of pesticides removed from the site would need to follow Oregon Pesticide Rule procedures as interpreted by EPA. This has implications well beyond any areas highlighted by DDx RALs.49*

**EPA Position:**

Section 3.4.9 of the 2016 FS discusses disposal management requirements and each alternative clearly discusses the disposal assumptions in the detailed evaluation of alternatives in Section 4 of the 2016 FS. Dredged material being disposed at an off-site landfill needs to be characterized and when required will be treated if a state or federal law requires it and/or the receiving facility requires it. If there is RCRA characteristic or listed hazardous waste contained in sediment, necessary treatment will be required. Additionally, dredged sediment containing MGP waste that exceeds TCLP criteria for MGP-related constituents and/or special considerations such as worker safety and equipment decontamination will need to be treated for disposal to be protective. [AR Doc ID # 1198486] Although not expected due to existing data, if there are dredged sediment that exceeds 50 ppm PCBs, disposal of such dredged sediment will need to comply with

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

TSCA's disposal requirements. At this time, no other dredged material is known to require treatment for off-site disposal.

Respondents did not provide specifics regarding what exactly about the waste management components was difficult for them to understand or what is inappropriate or inconsistent with existing requirements. EPA used the same methodology in developing disposal costs between the alternatives, the estimates are reasonable enough to compare alternatives. True costs will be determined at the time of disposal based on federal or state requirements and/or the requirements of the disposal facility.

**LWG Dispute Issue 1e:**

*Confined Disposal Facility (CDF) acceptance criteria – As the LWG previously commented, EPA made some of the CDF acceptance criteria and performance standards more conservative (Table 3.4-7) since the T4 CDF 60% design, even though EPA references that design as the source of the criteria and standards. This situation has not changed for the June 2016 FS. No rationale is provided for why the changes make the remedy more protective or effective.*

**EPA Position:**

Performance standards for the CDF are presented in Section 3.4.9.2 and Table 3.4-7 of the 2016 FS. The performance standards presented in Table 3.4-7 were taken directly from the CDF performance standards transmitted by EPA to the Lower Willamette Group (LWG) by letter dated February 18, 2010 and as subsequently presented in Table 5-1 of the Terminal 4 Confined Disposal Facility Design Analysis Report (Prefinal 60% Design Deliverable) [AR Doc # 100007974].

Section 3.4.9.2 of the 2016 FS included additional requirements for material that may be disposed of in an on-site CDF. These acceptance criteria prohibit placement of sediment designated as RCRA or state hazardous waste, sediment designated as "Waste or Media containing Waste that May Warrant Additional Management", PTW that is highly mobile or cannot be reliably contained, sediment containing free oil or NAPL, or material without suitable geotechnical or geochemical properties. These acceptance criteria are consistent with EPA directed modifications to the CDF as a result of public comment as presented in the Action Memorandum for a Removal Action at the Port of Portland Terminal 4 site with the Portland Harbor Site. [AR Doc # 1225662]

1. Only sediments from the Portland Harbor Superfund Site are eligible for placement in the saturated zone of the CDF.
2. No sediments that may be designated as characteristic hazardous waste or contain free-phase oil would be eligible for placement without treatment to control potential for release and migration of these substances.
3. Sediments must be of acceptable geotechnical character (to be defined during design) such that they do not impact the long-term performance of the CDF.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Sediments must undergo appropriate testing including bulk chemistry tests and pancake column leachate test (PCLTs) to document source characteristics acceptable for the CDF. Maximum chemical concentrations measured in representative PCLTs of the sediments must be protective (to be defined during design) of surface water quality criteria.

**LWG Dispute Issue 1f:**

*Cost estimates, volumes, production rates, and construction durations are inaccurate and lack transparency. The LWG previously commented on the August 2015 draft FS that EPA underestimated volumes and construction durations and used impossibly aggressive production rates and unattainable efficiencies given the required BMPs, complex disposal requirements, nearby residential community, and heavily used Willamette River. Due to these factors and other questionable costing approaches, the LWG commented that EPA's costs were substantially underestimated and consistently minimize the apparent costs of the larger alternatives and dredging, as compared to the smaller alternatives and capping. EPA's June 2016 FS cost estimates appear to exacerbate these problems, resulting in even lower overall costs for each alternative.*

**EPA Position:**

A significant portion of this dispute issue appears to be centered on differences of professional opinion regarding the technical viability and implementability of remedial activities. The information provided in the cost estimate is based on the best available information regarding the anticipated scope of the remedial alternatives, and thus the issue at dispute is the technical assumptions and not the costs that they reflect. The stated purpose for FS cost estimates in EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* (p.1-2) is to compare remedial alternatives during the remedy selection process. The stated accuracy in this guidance for FS cost estimates at the detailed analysis phase is +50 to -30 percent of actual cost. The cost estimates were reviewed by EPA's National Remedy Review Board (NRRB). The NRRB reviewed the FS cost estimates in November 2015 and indicated that the costs presented were generally in the range of costs at other contaminated sediment Superfund Sites. [AR Doc # 100001536] The NRRB, while determining that the costs used were reasonable when compared to other contaminated sediment Superfund sites, did recommend further evaluation of specific assumptions and related costs. EPA reviewed comments pertaining to cost estimates and made changes to assumptions for all alternatives and updated the cost estimates, as appropriate, to better reflect the anticipated scope of a future remedy for the Portland Harbor Site as it became further defined between November 2015 and the 2016 FS. For instance, EPA reviewed assumptions pertaining to treatment of contaminated sediment for consistency with early actions and also reviewed unit costs for remedy components such as capping and dredging to reflect consistency with the productivity rates anticipated in EPA's evaluations. Reevaluations of these assumptions, specifically due to more refined development of the alternative's scopes, resulted in lower overall costs in the 2016 FS than as presented to the NRRB in November 2015. EPA's position is that the cost methodology and sources used in the 2016 FS meet the stated accuracy range.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Additionally, the detailed cost backup and individual cost summaries for each alternative presented in Appendix G meet the documentation guidelines presented in Chapter 6 of EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*.

See EPA's position to LWG's dispute issue 2f regarding dredge volumes.

A detailed construction schedule generally is not produced in an FS because the level of scope definition is too low to make those design-level determinations. However, a cursory evaluation of construction duration was performed for the major construction components (capping and dredging) as indicated in Appendix D.3. It should be noted that schedules indicate a minimum duration and that longer durations only affect present value cost as estimated. The productivity rates presented in a memo to LWG on August 14, 2015, from USACE was used to calculate construction durations (**AR Doc # 100011624 and 100033480**).

The complexity of the disposal requirements is a factor of the material characteristics and is governed by regulatory considerations, which are presented Section 3.4.9.1 of the 2016 FS. EPA's position is that the complexity of the disposal requirements is appropriate for the expected material generated during remedial activities. The fact that LWG claims that the disposal requirements are too complex does not support the LWGs opinion that the cost estimates are substantially underestimated.

The cost estimate takes into account site specific difficulties expected with implementation. EPA developed project-specific unit costs using the Micro Computer Aided Cost Engineering System (MCACES) Second Generation (MII) software version 4.2, build 3. EPA's position is that the productivity rates along with the crew development used for development of site-specific unit costs are reasonable for an FS level evaluation and meet the stated accuracy range of EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*.

*Missing cost elements:*

*EPA's cost estimate does not include the 3 to 5 year anticipated "initial conditions" assessment, subsequent pre-remedial design investigations, or additional riverbank sampling and remediation contemplated in the FS and Proposed Plan to be identified in conjunction with this post-ROD sampling. At the Head of the Hylebos project, which was primarily a PCB remediation involving roughly 44 acres, pre-remedial engineering investigation costs amounted to roughly 16% of remedy implementation costs.*

**EPA Position:**

The remedial design percentage included as a percentage of the capital costs per EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* includes activities such as pre-design investigation and initial conditions assessment. As described in Section 5.5 of that guidance, engineering judgment may be used to adjust

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

rule-of-thumb percentages presented in Exhibit 5-8 for project management, remedial design, and construction management as well as the recommended range presented for technical support. As described in the 2016 FS, Appendix G, Attachment A, the percentages of professional and technical services costs are generally higher for projects of smaller scope and lower for projects of larger scope. The scope of the cleanup activities within the Portland Harbor Superfund site (thousands of acres) is much larger than the scope of the Head of the Hylebos project (tens of acres), and therefore it is expected that the percentage for remedial design costs used as a function of capital costs will be higher for the Head of Hylebos project and lower for the Portland Harbor Superfund Site.

The remedial design costs presented in the 2016 FS for each alternative were estimated to be comparable to remedial design costs estimated for alternatives evaluated in the Lower Duwamish Final FS, when reviewed on an annualized basis. The specific scope and costs for the “initial conditions assessment, subsequent pre-remedial design investigations, or additional riverbank sampling and remediation” will be identified during remedial design based on factors such as funding, phasing, and scheduling of work. Unknowns or unforeseen conditions for these activities and related costs not entirely captured in the remedial design percentage can be considered to be captured in the scope contingency applied to each alternative.

*EPA does not appear to include any Oregon Department of State Lands (DSL) costs for access, leases and easements required for investigation, dredging, capping and monitoring activities. In documents the LWG obtained through its FOIA request to EPA, EPA’s FS contractor acknowledged that these costs – which he characterized as “incredibly large” – were not included in the FS evaluations.<sup>50</sup>*

*<sup>50</sup> See, DEQ/EPA Cost Notes (January 28, 2016) (R10-100007897), p. 11 (Attachment 4).*

**EPA Position:**

Per EPA’s *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, fees not otherwise covered by a direct line item are covered by a percentage of the capital and periodic costs in the professional/technical oversight named “project management.” The EPA’s *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* defines “direct costs” of cleanup as “the equipment, labor, and material costs necessary to construct the remedial action (including contractor markups, such as overhead and profit).”

EPA acknowledges that the Board of State Lands through the Department of State Lands promulgated rules for granting and renewal of access authorizations, leases, and easements issued to facilitate remediation conducted pursuant to an order issued by ODEQ or EPA and habitat restoration activities in, on, under or over state-owned submerged and submersible land. In general, section 104 of CERCLA, 42 U.S.C. Section 9604 provides the President with broad authority to take response actions to protect

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

human health and the environment where there is a release or potential threat of a release into the environment of hazardous substances (or pollutants and contaminants presenting an imminent and substantial endangerment to public health and welfare). In addition, subsection (e)(3) of Section 104 specifically provides the President authority to access “[a]ny vessel, facility, establishment, or other place or property where entry is needed to . . . effectuate a response action under” . . . CERCLA. Furthermore, Section 121(e)(1) of CERCLA provides **that:** “[n]o State, or local permit shall be required for the portion of any removal or remedial action conducted entirely onsite, where such remedial action is selected and carried out in compliance with . . .” CERCLA. The statute provides clear authority for EPA to take or require cleanup actions be taken, and explicitly states that no permit or license is required to perform a response action on-site. We also note that as a general matter, the United States is not required to pay state or local fees, unless Congress explicitly so requires. EPA anticipates that PRPs, including DSL, will perform the Portland Harbor cleanup and reasonable terms of access to private and state-owned property to implement the remedy likely will be the subject of future negotiation between the PRPs, landowners, and DSL; however, what those terms will be and what if any compensation is agreed to is too speculative at this time.

*EPA’s cost estimate does not include agency oversight and participation costs. These costs have represented more than 27% of RI/FS costs at Portland Harbor.*

**EPA Position:**

Oversight costs are included as a percentage of the capital and periodic costs in the professional/technical oversight named "construction management" and "project management". See section 5.5 of EPA’s *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*.

*EPA’s cost estimate does not include the required 12-inch daily cover layer, which appears to be a new requirement to reduce dredging releases.*

**EPA Position:**

The cost estimate in the 2016 FS, Appendix G, includes the 12-inch dredge residual layer in the volume of sand. The 2016 FS does not prescribe this as a daily cover.

*EPA does not factor the need to acquire and develop transload facilities into the schedule.*

**EPA Position:**

The 2016 FS does not provide construction schedules for alternatives, which is more appropriate during remedial design. However, cursory evaluations of construction durations were included for purposes of implementability and cost evaluations within Appendix D.3. The feasibility study assumes that the development of transload facility will be included in the initial year of preparatory activities. The assumption of preparatory activities occurring in the initial year is stated in the 2016 FS, Appendix D, Footnote K of Table D3-1 (Construction Duration Assumptions). The initial year of

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

preparatory activities would include pre-design investigations and start-up activities prior to beginning construction (in-water work). It is assumed that start-up activities would include development of transload facility, mobilization, setting up of staging area, preparation of the CDF (if applicable), etc. Expansion of the transload facility or additional transload facilities (if needed) was assumed to be developed concurrently during construction (in-water work) for FS purposes. Start-up activities will be addressed at the appropriate phase of the work, which is in the remedial design workplan.

*Underestimated cost elements:*

*EPA continues to assume unattainable production rates and efficiencies assuming construction 24 hours per day for the basis of the project schedule and cost estimates. Stepping time is completely ignored. Furthermore, the need to operate in an active navigational channel will mandate the need to move the dredging equipment during each ship movement. According to the Columbia River Pilots Association there are 2 to 5 of such movements through this site daily. Each will represent a significant disruption and will result in significant loss of dredging and remedial project efficiency. The FS assumes that numerous requirements for innovative and complex dredge Best Management Practices (BMPs), precision dredging techniques, use of sheet pile barriers in some areas, and a transload and water treatment system (which will act as a bottleneck) will be performed simultaneously without incident or equipment breakdown, and with no additional time on costs.*

*We note that the Feasibility Study states that a fixed arm articulated bucket is the preferred dredging option where feasible and that a cable bucket will be used in water depths greater than 40 feet. This would correspond to the fixed arm bucket being used for roughly 80% of the dredge volume and cable bucket for 20%. However, the FS inconsistently assumes in the cost estimate and project schedule that the fixed arm bucket is used for 5% of the dredge volume. The cable bucket has a much higher production rate and lower unit cost than the fixed arm bucket. Correcting this assumption would increase alternative durations by 5 to 15 years, depending on 24- or 12-hour work days, respectively.*

*EPA continues to use aggressive dredging production rates. Sections 2.4.3 and 4.2.2.2 present a number of BMPs and controls to minimize impacts. These BMPs will slow dredging production and increase costs. The LWG's past production rates accounted for these anticipated BMPs which are likely needed to meet 404 water quality certification requirements but EPA's current rates do not.<sup>51</sup> Some of these described BMPs and controls include:*

- Sheet piling in select areas*
- Slowing the dredge cycle time to reduce bucket impacts at the bottom*
- Rinsing the bucket to clean off excess sediment between loads*
- Briefly stopping the bucket at the waterline to allow excess water to drain before raising bucket to barge*
- Having precision cuts of only 50% bucket fills on last passes*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

- *Pumping excess water from barges during dredging*
- *Placing a residuals cover daily*
- *Modifying the work schedule*
- *Performing work during low river flows*
- *Fish capture and removal inside work isolation areas*

**EPA Position:**

A memo was submitted to LWG on August 14, 2015 clarifying the development of the production rates based on an earlier review and recommendation by the Army Corps of Engineers (27-May-2013). [AR Doc # 100011624] The assumptions and calculations transmitted in the memo were included in Appendix D, Table D3-1 of the 2016 FS. In contrast to assertions made in the comment, stepping time, allowances for work disruption, and other impediments to dredging operations are accommodated in productivity rate estimates. USACE's 2008 *Technical Guidelines on Environmental Dredging* recommends the use of an Effective working time factor (p. 131): "Effective working time is the time during the dredging operations when actual production is taking place, such as material moving through the pipeline or being placed into a sediment barge. This is also referred to as "operating time." The Effective Work Time factor accommodates "when the dredge is operational but no production is taking place, such as time spent making changes to pipelines, cleaning debris from the suction head, changing sediment barges, moving the dredge, standing by for navigation traffic, making minor operating repairs, and refueling. This is also referred to as "allowable downtime." USACE's 2008 *Technical Guidelines on Environmental Dredging* (p. 93) states that the effective working time is "typically 55 to 70 percent for environmental dredging projects." The estimate used in the 2016 FS (62.5 percent) was the midpoint of that range. In this regard, dredge "operating time" is estimated to occur 15 of 24 hours, six days per week. The effective working time factor was explicitly used to accommodate issues identified by the commenters as well as other unforeseen circumstances. As stated in the 2013 memo from Dr. Paul Schroeder, USACE ERDC [AR Doc ID # 500001131], "A target production rate of 6000 cy/day, 6 days per week should be achievable even with the assumed efficiency impacts of resuspension control and residuals control and management if water quality, processing and disposal requirement can be met."

Regarding the estimate use of fixed arm vs. cable arm dredging, the 2016 FS, Appendix D, Table D3-1 states "Daily dredge production rates were developed assuming a 55/45 percent mix of cable arm versus articulated bucket dredges, based on the approximate areal percentages of navigation channel and maintenance dredge areas in the alternatives." It's acknowledged that the text in the main body of the feasibility study that is referenced by the commenters does not clearly state this basis (p. 3-22 of the 2016 FS states: "Cable-operated dredges are assumed for those Site conditions where fixed-arm dredges are not viable [such as water depths exceeding 40 feet] and will have no water depth limitations at the Site").

Overall, this and other comments on dredge production imply that overly high production rates falsely equate to shorter construction durations. Even if these FS-level production

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

rate estimates are high, other assumptions lessen the production rates. For example, the in-water construction duration is based on the assumption that “Cap and EMNR construction is assumed to occur in sequence (not in parallel) with dredging for estimating total construction” (2016 FS, Appendix D, Table D3-1). This means that all dredging would occur, then all capping would occur. This assumption is fine for its purpose (estimating a construction duration), but in practice, sequencing would not occur by technology type. Remedial action would be sequenced by area, generally moving from upstream to downstream, capping/dredging contaminated sediment, before moving on to the next area. It would not be reasonable to dredge a portion of an SDU and then return to that SDU two years later to begin capping the remainder of the contaminated sediment. As a result, estimated dredge volumes would be removed over the in-water construction duration, resulting in lesser production rates (e.g., Alternative I, has a 2.27 year estimate for dredging duration; 3.93 years of in-water construction, equating to a 42 percent lower annual production rate over the in-water duration). As a final point, because all alternatives have dredging to some degree, changes to the dredge productivity rates would have similar effects across all alternatives, and not significantly influence remedy selection.

*EPA also has aggressive dredging rates for riverbank excavations. It is assuming dredging will be completed from the water with a 6.5 cubic yard (cy) bucket loading a telebelt that will transfer material to a haul barge. It is using an aggressive cycle time of 50 seconds for this work yet still implies use of the same BMPs as described above for sediment work.*

**EPA Position:**

The 50 second cycle time quoted in the comment represents the “ideal cycle time” for riverbank excavation with barge mounted excavator. This does not take into account the 90 percent work efficiency factor and the 0.9 operator ability correction factor, which decreases the productivity. The information quotes in the comment from Appendix G of the 2016 FS was presented specifically for purposes of developing and checking the reasonableness of the presented unit costs (from the perspective of number of crews).

Having said that, the concern from the LWG about reduction of productivity due to use of BMPs is going to be location-dependent based on the type of contamination within the river adjacent to the riverbank and the sediment control BMPs used. Depending on the location-specific conditions, shoreline-based excavation of river banks may be desirable instead of water-based excavation to avoid the types of impediments suggested. Although for cost purposes riverbank excavation presented in Appendix G of the 2016 FS was developed assuming barge mounted excavator, the text of the 2016 FS presents the assumption that land-based excavators are assumed to be used for removal of contaminated river bank materials or near-shore sediment in locations above water levels. The actual approach used (land or water-based excavation) and related scope and costs for riverbank excavation are location-dependent and will be refined during remedial design. The assumption of water-based excavation for riverbanks does not impact the overall accuracy of the 2016 FS cost estimates.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*EPA's water treatment plant consists of holding tanks and carbon treatment with no additional costs. EPA indicates that the water will be discharged back to the river. Based on past experience in Portland Harbor, this approach is unlikely to be acceptable. T4 dredging required water discharge to the City's POTW. EPA also assumed that water treatment will only be required during the days of dredging. All precipitation will need to be captured and treated, so the system will be required as long as there is dredged material on site.*

**EPA Position:**

The water treatment costs presented in Appendix G of the 2016 FS, not only includes the costs of the components of water treatment (e.g. holding tanks, bag filters, and carbon adsorption on a skid mounted type system), but also includes crew costs for collecting water from dredging operations for treatment. For purposes of estimating costs, it is assumed that all necessary pretreatment (including dewatering) and handling of dredge materials will occur on the barge prior to arrival at a transload facility. There is no assumed stockpiling of material onsite nor at the transload facility, but that any water discharged from a stockpile area would be captured and treated. The cost estimates assume treatment of collected water on barges and discharge to the Willamette River after treatment.

The text of the 2016 FS indicates that wastewater will likely either require treatment prior to discharge to the lower Willamette River or disposal at a publicly owned treatment works (POTW) facility. While the 2016 FS necessarily assumes a representative set of water treatment process options for the general screening and alternative development procedures, this does not imply that other process options cannot be considered during remedial design. Use of a multi-stage filtration and granular activated carbon adsorption approach to water treatment is assumed as a holistic approach for all dredge material in the cost estimate. However, EPA acknowledges that an expanded treatment system may be required for some material, particularly PTW, on a location-specific basis. Unknowns or unforeseen conditions for these activities and related costs not entirely captured in the costs for water treatment can be considered to be captured in the scope contingency applied to each alternative. The scope and costs for wastewater treatment will be refined during remedial design on a location-specific basis.

*Appendix F indicates that Subtitle C material will be hauled to Boardman and then hauled by truck to ChemWaste, similar to what was done for the Gasco Early Action. However, the cost estimate only has 1 day of haul time to Boardman and 18 hours return. The cost estimate assumes that the material would be stockpiled on site at the Boardman transload facility and then loaded into trucks. The Boardman site, used previously for the Gasco Early Action, has only 4 to 9 acres of available space, with the high end of the range assuming that the current operations are terminated to allow for the transloading. This will not be sufficient for the anticipated Subtitle C material EPA plans to remove. For Gasco, the material was loaded directly from the barge to the trucks. The Gasco Early Action processed only approximately 15,000 cy of material, while Portland Harbor*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*will have an orders-of-magnitude-more volume, which will overwhelm the Boardman facility. EPA received a quote from ChemWaste to truck the material from Portland Harbor to their facility as an alternative. However, this would entail 10,555 truck trips of Subtitle C material through Portland neighborhoods.*

**EPA Position:**

The 2016 FS looks at modes of transport and associated transload of wastes from a macro perspective, but the primary assumption in the 2016 FS was to use barges for the purposes of implementability and cost evaluation. The 2016 FS also indicated that multiple modes of transport could be used and could be evaluated during remedial design phase of the project.

EPA talked with the representative facilities including ChemWaste, Port of Morrow (Boardman site) and the barging company (Tidewater Transportation & Terminals) and they did not indicate any significant concerns about logistics of transload of NRC/NAPL PTW waste volumes for transport and disposal at ChemWaste. It should be noted that Tidewater Transportation & Terminals was the barging company used for Gasco Early Action. Also, through discussions with the representative facilities, the cycle time in terms of barging and trucking reflects their cycle time input for a round trip. Based on these discussions and inputs following cycle time for barging was assumed in the FS cost estimates: 1 day of barge time to Port of Morrow (Boardman site) and 18 hours of barge time for return.

The 2016 FS cost estimate does not assume that the barged material would be stockpiled at the Port of Morrow (Boardman site) transload facility. Instead the 2016 FS cost estimate assumes direct loading in two steps; using a crane to offload from barge and a front-end loader to load the trucks. In addition, an offsite transload facility development cost was included to account for additional flexibility in transload. In terms of flexibility, as indicated in Appendix F of the 2016 FS, multiple modes of transport besides barging (rail or truck) could be used to transport waste to ChemWaste from transload locations as determined during remedial design. It should be noted that ChemWaste had indicated for budgetary purposes for the feasibility study that the cost of transport wouldn't differ significantly between the various modes of transport once transload was taken into account.

The ChemWaste landfill is assumed to only be used for disposal of NRC/ NAPL PTW. As compared to Gasco Early Action (~15,000 CY), the Portland Harbor Superfund Site remedial action will generate a large volume of waste material for disposal at ChemWaste (~285,000 CY); however this volume is assumed to be generated over a longer construction duration of 5 seasons as assumed for Alternative I. Based on these assumptions it is estimated that approximately 2,400 CY per week (which is approximately 1 to 2 barges per week) would be handled at the transload facility for disposal at ChemWaste. As mentioned above, the barging company, the transload facility, and disposal facility did not indicate any significant concerns about logistics of handling the required volume for transportation, transload and disposal.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*The cost estimate appears to assume the Subtitle D material is barged to Bingen and then hauled by truck to the Roosevelt Landfill. There is no analysis of whether the Bingen offloading facility could accommodate 6,200 cy per day of dredged material for processing. EPA is also assuming that diatomaceous earth is added into the sediments to absorb the free water, but they do not account for the \$9M in added tonnage for disposal.*

**EPA Position:**

The assumption in the 2016 FS for contaminated sediment disposed of at a Subtitle D facility is that it is barged to Bingen and hauled by truck to Roosevelt Landfill. EPA did have a discussion with Roosevelt Landfill facility about their ability to transload material from barge and they indicated the ability to accommodate the quantity that the project may develop, specifically including their ability to handle 6,200 cy/day of dredged material. They also indicated that there are sufficient options available since Roosevelt Landfill facility has agreements with a number of transload facility locations along the Columbia River including potential plans to build a new transload facility irrespective of this project (see 2016 FS Appendix G, Cost Estimate Backup Project- Specific Vendor Quotes).

LWG is incorrect that diatomaceous earth was not accounted for in the disposal costs. As described in the 2016 FS, Appendix D [D2.4 Treatment and Disposal Quantities, D2.16 Truck, Rail, Barge Loads for Disposal Volumes (DMM Scenario 1 - Confined Disposal Facility and Off-Site Disposal), and D2.17 Truck, Rail, Barge Loads for Disposal Volumes (DMM Scenario 2 - Off-Site Disposal)], the volume or tonnage of diatomaceous earth required for pre-treatment was considered and included in overall volumes and tonnages for transportation and disposal. These quantities were presented in the tables referenced in the 2016 FS, Appendix D2.4, D2.16, and D2.17, and were subsequently used in the cost worksheets for the alternative cost estimates within Appendix G. Also, the 2016 FS, Table D2.d, shows the calculations that illustrates the inclusion of diatomaceous earth for all dredged sediment (except those destined for CDF disposal under DMM Scenario 1).

*EPA does not provide any details on project schedule related to integration of dredging, daily covers, and caps. Capping materials alone include more than 800,000 cy. Two capping plants working 12 hours per day would be needed to place roughly 200,000 cy per season per LWG estimates; EPA's estimated rates are 600,000 cy per season from two plants with one working 24 hours per day and one working 12 hours per day.*

**EPA Position:**

LWG is incorrect that EPA does not provide any details regarding schedule related to integration of dredging and capping. The feasibility study does not provide construction schedules for alternatives, which is more appropriate during remedial design. However, cursory evaluations of construction durations were included for purposes of implementability and cost evaluations within Appendix D.3 of the 2016 FS. These evaluations were primarily based on the major construction components driving overall

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

durations (specifically capping, dredging, and in situ treatment) using the USACE-determined productivities as indicated in Appendix D.3 of the 2016 FS. This table explicitly documents the methodology used to arrive at the construction durations with respect to capping and dredging.

LWG is also incorrect regarding EPA's assumptions of the number of capping plants and their productivities. EPA assumed three plants, not two, operating 6 days per week with one day of maintenance per week. The estimated productivity of each of these plants is 1,500 CY per day (4,500 cy per day total) but that placement rate was reduced in the construction duration estimates to 3,900 CY per day for all three plants to account for a weekly average. These assumptions are stated in the 2016 FS, Appendix D, Assumption No. 4 in Table D3-1 (Construction Duration Assumptions).

*EPA continues to use a very simplistic approach to estimating dredge volumes, which has a large potential to substantially underestimate the dredge volumes eventually determined in remedial design.*

**EPA Position:**

EPA disagrees that a simplistic approach was used to estimate dredge volumes in the 2016 FS. EPA developed dredge volumes using "neat" line volumes based on interpolated area and depth data. To take into account side slope stability (dredge prism), neat volumes were multiplied by a factor of 1.5 to estimate the Low Volume with Overdredge, and by a factor of 2.0 to estimate the High Volume with Overdredge. Total volumes for each alternative were calculated as the average of the estimated low and high overdredge volumes. This is consistent with information presented in the Corps Technical Guidelines for Environmental Dredging of Contaminated Sediments (Palermo et. al., September 2008) – Section 3.4.3:

"For FS level considerations, an adjustment factor of 50 percent (i.e., an estimated dredge prism volume equal to 1.5 times the neat line prism volume) is appropriate for typical site conditions."

Guidance states that the ratio of dredge prism (including allowable overdraft) to the neat line prism (which is what EPA assumed in the 2016 FS) can be as high as 3 based on work at the U.S. Navy Homeporting project in Everett, Washington. However, it seems that the estimate of dredge prism to neat line ratio of 1.5 – 2.0 is reasonable for Portland Harbor and consistent with the guidance for an FS level evaluation. During remedial design, dredge prisms will be developed that minimize the amount of material that will need to be removed through dredging.

*EPA uses the same 7% discount rate as used in the EPA 2015 draft FS, which heavily discounts the larger alternatives (i.e., Alternative E is discounted a total of 41% and Alternative G is discounted by 77%). This discount rate is indicated on the first page of EPA's 2000 cost estimate guidance for FSs. However, the second complete paragraph on Page 4-5 of that guidance indicates that a different discount rate can be used as long as*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*it is justified consistent with OMB Circular A-94. Accordingly, the LWG's 2012 draft FS used a discount rate of 2.3%, consistent with guidance as explained in that document. The equivalent treasury rate for 2016 is 1.5%, which is a much more appropriate discount rate at a site where the PRPs include the United States, the State of Oregon, municipalities, public utilities, and many parties whose principal or only source of funding for cleanup are insurance funds outside their investment control. It is also the rate that EPA would presumably use in calculating required financial assurance.*<sup>52</sup>

*52 2016 Discount Rates for OMB Circular No. A-94, M-16-05 (Office of Management and Budget, February 12, 2016)*

**EPA Position:**

As discussed in EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 540-R-00-002), the real discount (interest) rate used for present value analysis in the FS depends on whether the site is classified as a Federal facility site. Federal facility sites are former or current installations operated or controlled by a Federal government agency and identified by EPA's Federal Facilities Restoration and Reuse Office (FFRRO). The Portland Harbor Superfund Site is not a Federal facility identified within FFRRO's site inventory. In addition, the guidance specifically mentions that although a Federal-lead site cleaned up by EPA using the Superfund trust fund (Fund-lead sites) may be an analogous situation to a Federal facility site being cleaned up using Superfund authority, there is always a chance that a potentially responsible party (PRP) could remediate the site. Thus, per guidance a real discount rate of 7 percent should be used in calculating present value costs for all non-Federal facility sites such as the Portland Harbor Superfund Site. This expectation is documented in the last paragraph of Page 4-5 of the guidance.

EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* in the second paragraph on page 4-5 also specifically states that any changes to EPA's policy to use a 7 percent discount will be reflected in an update to OSWER Directive 9355.3-20. EPA has not updated that directive, and thus use of a 7 percent real discount rate is still the expectation per that directive. Furthermore, while the statement that a differing discount rate can be considered based on a change to the discount rate within OMB Circular A-94 is correct, OMB has not changed from a 7 percent real discount rate (see Paragraph 8(b)(1) of OMB Circular A-94). Updates to discount rate in Appendix C of OMB Circular A-94 are not considered changes to the policy (see second paragraph on Page 4-5 of EPA 540-R-00-002 and related Footnote 3).

LWG also asserts that a differing discount rate should be used to be consistent with financial assurance practices used for these types of sites that use funding from PRPs. As indicated on Page 2-3 of EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study*:

As a project moves from the planning stage into the design and implementation stage, the level of project definition increases, thus allowing for a more accurate cost estimate. An

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

“early” estimate of the project’s life cycle costs is made during the FS to make a remedy selection decision.

At the FS stage, the design for the remedial action project is still conceptual, not detailed, and the cost estimate is considered to be “order-of-magnitude.” The cost engineer must make assumptions about the detailed design in order to prepare the cost estimate. As a project progresses, the design becomes more complete and the cost estimate becomes more “definitive,” thus increasing the accuracy of the cost estimate. This process is depicted in Exhibit 2-3 for remedial action projects in the Superfund program.

Further, EPA’s *Guidance on Financial Assurance in Superfund Settlement Agreements and Unilateral Administrative Orders* (p. 5) states:

2. Considerations for applying a discount rate for FA

A discount rate is the interest rate used in calculating the present value of expected future costs.<sup>16</sup> As noted in existing EPA guidance for documenting cost estimates during the FS, the Agency generally uses a 7% real discount rate to compare alternatives during the remedy selection process.<sup>17</sup> The goal of that guidance was to improve consistency, completeness, and accuracy of cost estimates developed specifically during the feasibility study phase of the Superfund remedy selection process, but not to offer guidance on determining an FA amount.

FA requirements are generally designed to ensure that sufficient funds are available for the government or another party to complete cleanup work if a PRP does not perform the required work. The Agency believes that FA based on a 7% discount rate could be insufficient to perform the work because funds called in from FA mechanisms are typically deposited into “special accounts”<sup>18</sup> or standby trusts, which are unlikely to grow at this annualized real rate.

<sup>16</sup> If a discount rate is applied to a cost estimate to establish an FA amount, it would take into account the time value of money—the general idea that a dollar today is worth more than a dollar tomorrow—by assuming that the initial FA amount would appreciate over time at a projected growth rate. The higher the discount rate that is applied, the less FA would initially be required, and the more it would need to appreciate to meet the anticipated funding needs at the site.

<sup>17</sup> See EPA Office of Solid Waste and Emergency Response, OSWER 9355.0-75, A Guide to Developing and Documenting Cost Estimates During the Feasibility Study (July 2000), p. 4-4, available at <http://www.epa.gov/superfund/policy/remedy/pdfs/finaldoc.pdf> (stating that the “specified rate of 7% represents a ‘real’ discount rate in that it approximates the marginal pretax rate of return on an average investment in the private sector in recent years and has been adjusted to eliminate the effect of expected inflation”).

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

<sup>18</sup> Special accounts are site-specific, interest-bearing accounts within the Superfund. For documents concerning special accounts, view the Special Accounts category in the Superfund enforcement policy and guidance database, available at [http://cfpub.epa.gov/compliance/resources/policies/cleanup/superfund/index.cfm?action=3&sub\\_id=1235](http://cfpub.epa.gov/compliance/resources/policies/cleanup/superfund/index.cfm?action=3&sub_id=1235).

Thus, the development of cost estimates in the 2016 FS was consistent with EPA's cost and financial assurance guidance and used the appropriate discount rate where the primary purpose is for comparing remedial alternatives during the remedy selection process.

It should be noted that while EPA used a 7 percent real discount rate for presentation of the alternative costs, a sensitivity analysis was performed for varying discount rates and presented in Appendix N of the 2016 FS. This is consistent with the recommendation in the third paragraph on Page 4-5 of EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study*.

*EPA used a low mobilization/demobilization factor of 1.6%, while the 2012 draft FS used a 15% factor based on project experience at similar sites. EPA is basing its 1.6% percentage on the cost estimate used for the Lower Duwamish River FS—not real construction data.*

**EPA Position:**

LWG is correct that construction data were not specifically used for determination of the mobilization/demobilization factor. However, EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 540-R-00-002), actual construction data is not required to be solely used. As indicated on page 5-6 of that guidance, "experience with similar projects, including both estimates and actual costs (bold emphasis added) can also be used as a source of cost data."

In addition, the determination of the percentage of the capital and periodic costs for mobilization and demobilization was based not just on review of Lower Duwamish River FS, but also the Passaic River FS, projects of similar scope and the equipment proposed for Portland Harbor FS.

The types of dredge can cap placement equipment proposed in the Portland Harbor 2016 FS (the primary pieces of equipment requiring mobilization/demobilization from beyond metro Portland) are fairly conventional in that they are barge mounted excavation and placement equipment and not unique types of dredge equipment such as suction dredges. In addition, the number of dredge plants and capping plants and attending scow barges and tugboats are relatively small given the duration of the project. Thus they should readily available in the Pacific Northwest given the multitude of shoreline projects along the Willamette and Columbia Rivers. EPA has thus assumed mobilization and demobilization are representative of expected regional mobilization and demobilization costs.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

The use of a percentage of capital costs for mobilization and demobilization of equipment is reasonable for the FS level of scope detail and assumptions. Real construction data will be evaluated and presented during remedial design as necessary.

It should be noted that unlike alternatives for some Superfund projects, the primary differences between the alternatives for the Portland harbor Superfund Site is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. Because the differences in capital and periodic costs are primarily based on quantity differences, the use of lower percentages for mobilization/demobilization costs do not impact the comparative aspects of the costs estimates between alternatives.

*EPA used a contingency factor of only 20%, while the LWG's 2012 draft FS used 40%. EPA guidance indicates that the overall contingency for an FS should be in the 20 to 45% range. Thus, EPA is using the lowest possible contingency factor allowed by guidance. EPA cites guidance indicating that larger projects with high costs may have lower overall contingency factors. This may be true for some types of projects, but given the complexity of this Site and the large number of issues that will be refined in design, using the lowest possible contingency factor appears very optimistic and greatly decreases the estimated costs of the alternatives, particularly the largest alternatives.*

**EPA Position:**

The stated accuracy in EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* for FS cost estimates at the detailed analysis phase is +50 to -30 percent of actual cost. EPA's position is that the cost methodology and sources used in the FS meet the stated accuracy range. The information provided in the cost estimate is based on the best available information regarding the anticipated scope of the remedial alternatives.

As described in Section 5.4 of EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, engineering judgment may be used to adjust rule-of-thumb percentages presented in Exhibit 5-6 for scope contingency with a lower contingency indicating that project scope will undergo minimal change during design. Due to the detailed level of conceptual design performed as part of the technology assignment modeling in the 2016 FS, the contingency percentages were modified to the low end of the recommended range presented in the guidance, to better reflect the detailed evaluation and concepts developed for the following items:

Per EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, contributing factors to scope contingency include the following:

- Limited experience with certain technologies
- Inaccuracies in defining quantities or characteristics
- Potential requirements due to regulatory or policy changes

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Scope contingency would be expected to be higher for newer or emerging remedial technologies than for more well-documented systems. Each alternative was developed using similar technologies and major work activities. Conventional and proven technologies were used in the development of the alternatives with only few exceptions (in situ treatment areas) representing a relatively small percentage of the scope.

The primary differences between the alternatives is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. The development of the RALs for each alternative established a boundary for the horizontal limits of dredging/capping based on available boring data. There is a vertical limit for dredge volumes in the shallow and intermediate areas based on the technology assignments, and this will limit the risk for potential growth of volume estimates in those areas.

EPA assumes all NAPL PTW will be dredged in the Navigation and FMD areas. However, the Willamette River currently has an authorized channel depth of -40 feet Columbia River Datum (CRD), and contamination at depths greater than the authorized depth of the navigation channel may be capped as long as the cap integrity is not impaired by future maintenance dredging.

Federal and State regulations were carefully evaluated and taken into consideration in the assignment of technologies (mitigation and floodrise) for development of all alternatives.

EPA ultimately selected a scope contingency (10 percent) within the parameters suggested by the guidance, after taking this information into account. For instance, Exhibit 5-6 of EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* indicates a recommended scope contingency range of 5 to 10 percent for surface grading/diking, 5 to 15 percent for bulk liquid processing, 5 to 15 percent for on-site and off-site disposal, 10 to 20 percent for sludge stabilization. All of these are activities that are part of the scope of the Portland Harbor alternatives and are at within the range of the scope contingency selected by EPA. While vertical barriers (10 to 30 percent) and soil excavation (15 to 55 percent) are at or higher than the selected value, the refined development of quantities and scope in the 2016 FS minimize the likelihood that significant unknowns and uncertainties remain that would result in large underestimation of costs requiring scope contingency.

Bid contingency accounts for changes that occur after the construction contract is awarded. Examples include:

- technological, geotechnical, and other unknowns applicable to the construction phase
- changes due to adverse weather
- material or supply shortages

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Conventional and proven technologies were used in the development of the alternatives with only few exceptions. The site specific unit costs developed for the Portland Harbor Superfund Site and presented in Appendix G of the 2016 FS were generally in the range of costs at other contaminated sites in the Pacific Northwest. This reduces the risk of technical constraints during contractor bidding. Inputs and assumptions used in the development of the construction duration calculations included an in-water work window which is appropriate for the region.

A vast majority of the materials and supplies identified as necessary for remedial action are conventional and readily available (sand, DE, quick lime). EPA assumes commercial source of capping materials, and assumes that more than one source may be required. EPA confirmed that commercial suppliers could supply the required volumes.

EPA ultimately selected a bid contingency (10 percent) within the parameters suggested by the guidance, after taking this information into account. Page 5-11 of EPA's *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* indicates a recommended scope contingency range of 10 to 20 percent. This is within the range of the bid contingency selected by EPA.

Unlike alternatives for some Superfund projects, the primary differences between the alternatives for the Portland harbor Superfund Site is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. Because the differences in capital and periodic costs are primarily based on quantity differences, the use of lower percentages for contingency do not impact the comparative aspects of the costs estimates between alternatives.

*EPA used lower percentages for project management (2%), remedial design (2%), and construction management (3%) than EPA guidance (5%, 6%, and 6%, respectively). These factors are also lower than the 2012 draft FS, which used 15% for remedial design and a monthly rate for project management and construction management. Remedial engineering design costs at the Head of the Hylebos were roughly 15% of actual project costs.*

**EPA Position:**

As described in Section 5.5 of EPA's *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, engineering judgment may be used to adjust rule-of-thumb percentages presented in Exhibit 5-8 for project management, remedial design, and construction management as well as the recommended range presented for technical support. As described in the 2016 FS, Appendix G, Attachment A, the percentages of professional and technical services costs will be higher for projects of smaller scope and lower for projects of larger scope. Due to the high overall costs for major work activities, the professional/technical percentages were modified to lower than the recommended

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

range presented in the guidance, to better reflect realistic costs for professional/technical services costs for these items.

It should be noted that unlike alternatives for some Superfund projects, the primary differences between the alternatives for the Portland harbor Superfund Site is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. Because the differences in capital and periodic costs are primarily based on quantity differences, the use of lower percentages for these professional/technical services costs do not impact the comparative aspects of the costs estimates between alternatives.

See EPA's position above for additional information on basis for reduced remedial design percentage compared to Head of the Hylebos project.

*There are significant equipment and contracting issues associated with executing multi-year projects where tens of millions of dollars of equipment need to be mobilized to the Site. The cost estimates do not factor in the standby costs created by idle equipment for two thirds of each year while the construction window is closed.*

**EPA Position:**

The unit costs were developed assuming conventional equipment. It is assumed that market conditions in the Pacific Northwest and utilization of this conventional equipment for other projects will minimize standby time between work windows and costs incurred for standby outside the work window would be covered by contingency. See EPA's position above for additional information on mobilization and demobilization.

*In Section 4.2.2.2, EPA discusses the need for air monitoring. Air monitoring costs do not appear to be included in the cost estimate. The June 2016 FS also cites the need for fish tissue monitoring during construction which is not reflected in the costs.*

**EPA Position:**

Site-wide monitoring is included as a capital cost in year 1 and also as a periodic cost incurred every other year for the first 10 years and every 4 years through the period of analysis. Unit costs for these monitoring efforts were developed by Anchor QEA in the draft 2012 FS, and include fish tissue monitoring. Additionally, costs for environmental monitoring during offloading at transload facility is included in the estimate for transload facility development for the duration of construction. The unit cost allowance for environmental monitoring during offloading at transload facility were developed by Anchor QEA in the draft 2012 FS, and include costs for boat, monitoring equipment and chemical analysis.

As part of ARAR discussions in Section 4.2, air monitoring is identified as required "to ensure that contaminants that volatilize would not exceed acceptable health based concentrations and adversely affect local communities and workers." Air monitoring is a

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

minor scope component for the alternatives given that the majority of contamination in sediment throughout the Portland Harbor (PCBs, pesticides) does not readily volatilize. Location-specific needs for air monitoring (particularly PTW at the Area 6W and 7W SDUs) will be addressed during remedial design. The scope of site-specific air monitoring requirements will be identified during remedial design, and costs for these are captured in the scope contingency of the 2016 FS alternatives cost estimates given that the requirements at this time are not fully known.

**LWG Dispute Issue 3**

*The FS fails to articulate a clear and understandable framework and schedule for implementation by which each alternative can be compared. For example, the FS states that “all the alternatives assume the remedy will be implemented as described. That is, there would be no changes identified during remedial design. However, due to the uncertainty inherent at Superfund sites, there will be adjustments made throughout the design and construction process.”<sup>3</sup> Nothing in the FS describes what adjustments are possible or how those adjustments would be determined, and, in contradiction to this assertion, EPA’s prescriptive technology assignments are carried through to the Proposed Plan. Similarly, the timeframes for all alternatives are described to include a “Year 0” “initial conditions” assessment expected to take 3 to 5 years to complete, and a subsequent set of “Year 0” start-up activities, including “pre-design investigations.”<sup>4</sup> No time is allowed in the schedule for preparation and approval of actual remedial engineering design. “Year 0” is also identified as “the first year of construction.”<sup>5</sup> Therefore, “Year 0” for all alternatives appears to mean more than 3 actual calendar years, but it is impossible to tell from the FS how many actual calendar years are rolled up into “Year 0” for any given alternative. EPA should provide a realistic vision and timeframe for implementation of its alternatives, and EPA should clearly identify in its alternatives development and decision trees that sediment management areas and technology assignments and process options will be refined and adjusted through remedial design and implementation.*

***The EPA June 2016 FS fails to articulate a clear and understandable framework and schedule for implementation by which each alternative can be compared.***

*EPA’s June 2016 FS continues to be very unclear on EPA’s vision for actual implementation of its selected remedy. On the one hand, it suggests in a few places that some elements of the remedy will need to be further defined or adjusted or modified during remedial design. On the other, it states definitively that the “remedy will be implemented as described. That is, there would be no changes identified during remedial design.” Further, the schedule outlined by EPA for remedial implementation is impossible on its face – as discussed above, “Year 0” for every alternative contains a minimum of 4 years of activities.*

*Generally speaking, EPA continues to use a prescriptive set of technology evaluation and scoring criteria to determine the technologies to be applied in each area of the site. Given the deficiencies in the FS described above, and given the lack of evaluation of*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*SDU-specific information, Figure 3.8 presents an entirely-too-prescriptive approach to technology assignments. As the LWG previously commented, EPA's approach prevents meaningful comparison of the performance of various technologies in the FS, and because the technology assignment is based on FS-level information, the prescriptive set of evaluation criteria will not appropriately or accurately predict the most appropriate technology assignments or configurations for remedial design based on data available at the time of design, including data collected post-ROD. For example, those assignments are based on overall general assumptions regarding slopes, presumed "wave zones," and required depths of removal to reach protective levels. With respect to riverbank contamination and presumed groundwater contamination, they are based solely on those general broad designations, without consideration of which COCs are present and conditions of exposure. By contrast, the Corps of Engineers capping guidance document provides design level guidance of modeling and assessment methods to determine the concentration of contaminants of concern that can be safely isolated by capping. EPA's process and these figures should build in the flexibility needed to evaluate the likely performance of technologies against RAOs in the context of the complexities of each particular SDU.*

*EPA should clearly explain the conditions under which changes to major alternative elements (e.g., changes in technologies assignments, methods to address PTW, methods for determining treatment and disposal requirements, requirements for rigid containment) might be considered or allowed. EPA should explain how new data, including the "initial conditions" assessment will affect the RAL boundaries based on surface sediment concentrations. The FS should include language to allow for updates to risk assessments. EPA should incorporate decision frameworks, such as the capping demonstration decision tree that was discussed during development of the June 2016 FS. No defined processes are in place for proposing equally or more effective capping options or other technology refinements based on detailed design-level evaluations and new data. EPA should explain how the remedy would be implemented spatially (e.g., operable units, groups of SMAs) and provide transparent and reasonable disclosure of when the community can expect cleanup to actually begin.*

**EPA Position:**

The LWG provided no regulatory or guidance support for their contention that the 2016 FS should have contained a framework and schedule for implementation. Neither the NCP nor FS guidance speaks to the need for a schedule for implementation for each alternative. The gist of the LWG's concerns appear to be more about wanting to know what the areas of flexibility may be in applying the decision trees moving into implementation because they read the 2016 FS to say that no changes to the technologies could be made in remedial design.

The LWG's concern is unfounded. The LWG took the 2016 FS quote from page 3-39 out of context and misinterpreted it. Here is the full text of the relevant FS section:

Remedy Implementation

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

For the purposes of the FS and developing remedial alternatives, the sequence of dredging is assumed to be from RM 11.8 to RM 1.9. However, during remedy design and construction, it may be more effective to deviate from this approach.

All the alternatives assume the remedy will be implemented as described. That is, there would be no changes identified during remedial design. Due to the uncertainty inherent at Superfund sites, there will be adjustments made throughout the design and construction process.” Page 3-39 of 2016 FS.

Furthermore, a word search for “remedial design” in the 2016 FS found 23 issues on which the document stated that further evaluation in remedial design would be necessary. Further, the 2016 FS acknowledges in several places that the technology assignments were **assumed** for various areas.

**LWG Requested Relief #1**

*EPA's June 2016 FS should not be used as a basis for a Record of Decision for the Portland Harbor Superfund Site.*

**EPA Position:**

The 2016 FS is based on good science – many principles are from LWG’s draft 2012 FS, data collected by LWG during the RI phase, and consistent with the findings of the baseline risk assessments, the NCP and EPA policy and guidance for developing an FS.

**LWG Requested Relief #2**

*The alternatives analysis in the LWG's 2012 FS provides an adequate basis for selecting a remedy at the Site.*

*The Disputing Respondents stand behind the LWG’s 2012 draft FS, which incorporated good science, provided the required comparative analysis of alternatives, and relied on realistic estimates of cost and time to perform work. The Disputing Respondents were prepared to fully engage with EPA and resolve EPA’s comments and concerns in order to produce a report that provided a credible basis for EPA’s selection of a remedy that conformed to CERCLA, the NCP, and EPA guidance. EPA’s unwarranted deviation from the RI/FS process agreed to by EPA in 2001 and set forth in the NCP has created a methodology that does not allow sufficient time for review, consideration and revision of the flawed FS, and is an abuse of discretion. A Record of Decision based upon the June 2016 FS will likely lead to an ineffective cleanup that cannot be implemented in a timely manner.*

**EPA Position:**

By letter dated, December 18, 2012, EPA disapproved the LWG’s 2012 draft FS and provided a list of seven significant deficiencies with the 2012 draft along with a table of 96 comments raised by the Technical Review Team. [AR Doc # 100007297 through 100007299] As described in the Introduction Section of this Response, EPA has been

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

transparent and open about the modifications it viewed were needed to the LWG's 2012 draft FS and shared drafts of its modifications with the LWG over the past two to three years. The LWG has had significant opportunity to raise its concerns, which they fully took advantage of, which our administrative record demonstrates. The deficiencies EPA identified with the LWG's 2012 draft FS, not surprisingly comprise many of the issues the LWG now dispute. They even continue to dispute the background methodology that EPA's Dispute Official thoughtfully considered and documented his rationale for upholding EPA's methodology. The LWG has had significant due process to raise its issues throughout the RI/FS development, but EPA had legitimate concerns with the LWG's draft FS. The modifications that EPA made to the FS are supported by the administrative record and consistent with CERCLA, the NCP, and EPA guidance.

Contrary to their February 2016 agreement that it was appropriate for EPA to finalize the FS, the LWG complains that EPA should have worked with them to solve the problems with their 2012 draft FS and it was an abuse of discretion for EPA to have finalized the FS rather than use their draft FS. Page 22 of LWG Dispute Statement. The relief they seek is that EPA should use their 2012 alternatives analysis for selecting a remedy at the Site. Although the scope of this dispute is limited to issues about the 2016 FS, the LWG have placed at issue the quality of the alternatives analysis in their 2012 draft and whether that analysis should be used to make the remedy decision, to which we must provide a response.

As the various responses to dispute issues above have noted, EPA used a lot of the LWG's analysis from their 2012 draft FS, which at the time they submitted it, they heralded it as sufficient for decision-making. As demonstrated above, many of their problems with EPA's 2016 FS is based on their analysis they now claim is flawed or should not have been used. Apparently if the analysis is in EPA's 2016 FS its wrong, but it's fine and useable in their 2012 draft FS. The deficiencies and comments contained in EPA's December 18, 2012, letter document sufficient basis to deny the relief they now seek. Additionally, a more detailed analysis of the failings with their hydrodynamic and sediment transport ("HST") model is contained in Section 4.2.1 and Appendix H of the 2016 FS. The LWG's flawed HST model was a fundamental basis for their alternatives analysis and conclusions; therefore, any decisions based on their alternatives analysis would also be significantly flawed.

EPA has fully considered all of the issues that the LWG, collectively, as well as individually have raised on EPA's 2016 FS. Many of the LWG's issues do not even apply to the 2016 FS, but rather were issues they raised on the August 2015 draft which EPA addressed in the 2016 FS. Likewise, other concerns they raise are actually concerns about their own analysis that EPA used in developing the 2016 FS. The LWG has not provided any reason for EPA to abandon its 2016 FS. EPA complied with the CERCLA, the NCP, and EPA guidance in developing its 2016 FS and it is more than adequate for supporting a final remedy decision for the Portland Harbor Site.

## **SDU and Upland Site Specific Issues for Disputes**

### **Arkema Dispute Issue 1 - Riverbank contaminants adjacent to the Arkema Site**

*EPA added sites and edited the discussion of riverbanks and groundwater in Section 1 of the FS.*

*Based upon our preliminary review, the identification and presentation of these sites contain multiple errors. For example, PCBs are listed as a riverbank contaminant at Arkema, but have only been detected in a small number of samples below the applicable screening levels (with one exception, one sample slightly exceeded a conservative bioaccumulative SLV). Two key issues are: (1) risk-based PRGs should not be established based on exposure pathways being evaluated as part of the upland source control evaluations under DEQ, and (2) that none of these upland media were evaluated in the BLRAs or RI. EPA's use of sediment PRGs for riverbanks, which were applied to areas rarely inundated by the river and without considering fate and transport (e.g., attenuation), is technically unsupportable and inappropriate. Delineations of groundwater plumes and riverbanks, and a zero post-construction restoration timeframe are unsupportable.*

*There is a lack of data and analysis as to what risk considerations are driving the specific remedial actions (and therefore how such analyses will be refined in the design phase when further data/analysis is available) and what specific remedial actions will be implemented in which areas driven by such risks. This opaque delineation is then carried into the evaluation of alternatives and used to assess the relative effectiveness of alternatives. This appears to significantly bias the outcome of alternative selection.*

*The June 2016 FS fails to include a discussion of upland source controls that have been implemented as well as failing to include anything related to the performance of source controls in the remedial evaluations.*

*Source control measures taken at the Arkema Site have largely eliminated the stormwater pathway from this site. Groundwater controls, namely the installation of a slurry wall and a groundwater extraction and treatment system designed to prevent migration from the uplands to the river, have eliminated the groundwater pathway.*

### **EPA Position:**

See EPA's position to LWG's dispute issue 1q.

### **Arkema Dispute Issue 2 - Principal Threat Waste adjacent to the Arkema Site**

*EPA inappropriately identifies chemicals in sediment adjacent to the Arkema Site as PTW based on either a "source material," "not reliably contained," or "highly toxic" criterion. Source material has never been identified in Arkema Site sediment, EPA should not identify chemicals that can be reliably contained as PTW, and chemicals that require long-term exposure durations through indirect exposure pathways (i.e., consumption of fish tissue) should not be identified as "highly toxic." In addition, the blanket identification of large areas with low concentrations of chemicals in sediments as PTW is*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*neither required by the National Contingency Plan (NCP) nor necessary to protect public health or the environment.*

*EPA errs when it misidentifies source material based on “globules or blebs of product in surface and subsurface sediments...” and when it states that “NAPL observed in sediment cores offshore of Arkema contains chlorobenzene and DDT (dissolved).” Arkema responded to CDM Smith’s 2013 memorandum (Attachment Ark-1) that purports to identify NAPL at the Arkema Site. To resolve the issue, Arkema prepared a work plan in response to EPA requests under the EE/CA Administrative Order on Consent (AOC) to confirm that NAPL was not present in sediment adjacent to the Arkema Site (Integral 2016). In addition, no samples offshore of the Arkema Site have identified the presence of an MCB DNAPL. There is no data that supports EPA’s statement that NAPL observed in Arkema sediment “...contains chlorobenzene....” Significantly, a document titled “Top 10 State Issues for Proposed Plan” obtained from the LWG’s Freedom of Information Act (FOIA) request identified that based on Oregon DEQ’s review of the data “The multiple phases of sediment investigation have not encountered sediment exhibiting NAPL saturated conditions that would warrant thermal treatment prior to management.” The status column for the same issue states that “EPA agreed to not assume NAPL at Arkema for the purposes of the cost estimate” (Attachment Ark-2). Based on these records, we conclude that EPA and DEQ agreed that there was no chlorobenzene NAPL in offshore sediments, and therefore the assertion that such sediments represent PTW Source Material as defined by EPA’s PTW fact sheet is without foundation, acceptance, or support.*

*EPA also erred when it identified an extensive area of groundwater containing chlorobenzene DNAPL discharging to the river as “not reliable contained” (Attachment Ark-3). In fact, there is no documented MCB DNAPL groundwater plume. EPA’s Figure 3.2-4, adjacent to the Arkema Site, is inaccurate and misleading. The nature and extent of chlorobenzene DNAPL in groundwater and/or sediment pore water as shown in this figure is not based on actual site data. Groundwater SCMs have been implemented at the site beginning in 2012, including an upland groundwater barrier wall and extraction and treatment system. The groundwater pathway to the river from upland areas where chlorobenzene DNAPL may have been present in upland groundwater has been isolated from site sediments. Containment has been in existence for nearly four years.*

*There is no scientific evidence that supports the existence of an ongoing source of MCB DNAPL to the sediment adjacent to the Arkema Site. Groundwater and pore water sampling conducted after the implementation of the SCM has not identified a MCB DNAPL source to sediment adjacent to the Arkema Site. This site characterization error which postulates an extensive area of chlorobenzene DNAPL in sediment at the Arkema Site biases the assessment and comparison of the effectiveness of alternatives as evidenced from the following text: “Alternative D has less capped area (71 acres), but does not reliably contain all PTW remaining in the river.” (USEPA 2016, p. ES-15). Without an accurate assessment of PTW and PTW areas (in this case, DNAPL), EPA’s alternatives evaluation is highly inaccurate.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*EPA also errs when it misidentifies areas of the Arkema Site (including certain areas upstream and downstream of Arkema; Attachment Ark-3) as containing “highly toxic” PTW based on surface sediment concentrations for DDX, 2,3,7,8-TCDD, 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, and 1,2,3,4,6,7,8-HxCDF that exceed a 10<sup>-3</sup> excess cancer risk level for fish consumption based on the fish ingestion risks from the baseline human health risk assessment (BHHRA). This definition of highly toxic based on a long-term (30-year) exposure to a chemical substance via a fish consumption pathway is not consistent with the intent of EPA’s PTW fact sheet. These 10<sup>-3</sup> risk levels include long-term exposure parameters and indirect exposure based on a 30-year subsistence fish consumption scenario, which does not meet the definition of highly toxic (i.e., toxic under a direct contact or acute exposure scenario). Highly toxic levels should be based on direct exposure conditions only. Furthermore, the 10<sup>-3</sup> excess cancer risk is only a suggested basis and is not prescriptive.*

*The EPA’s proposed highly toxic PTW levels should also be considered in a broader context.*

*EPA’s highly toxic PTW values for some constituents are well below cleanup levels and screening level for unrestricted use established for other sites and scenarios. For example, the PCB PTW value of 200 µg/kg is below cleanup goals for many other CERCLA sites, which are at or above 200 µg/kg. The EPA regional screening level (RSL) for residential soil in fact is 249 µg/kg; in other words, soil/sediment with PTW levels specified in the FS could be used as clean fill at homes, schools, and day care facilities. In this context it does not make sound technical or risk management sense for the PTW level to be set at 200 µg/kg.*

*An approach more consistent with the intent of EPA’s PTW guidance would be to set the PTW level at a 10<sup>-3</sup> risk value based on direct contact to sediment (removal action objective 1 [RAO1]); that would be the lower of the 10<sup>-3</sup> risk level (370,000 µg/kg), the hazard quotient (HQ) of 10 (147,600 µg/kg) (as stated in the guidance), or for the PCB case, the TSCA waste threshold (50,000 µg/kg). The use of the TSCA threshold for PCBs is also consistent with decisions at other CERCLA sites. A similar approach should be taken for the other constituents for which highly toxic PTW has been identified, especially dioxins/furans for which the PTW level in the FS is less than 3 times the EPA-recommended preliminary remediation goals PRG for dioxins/furans (once toxicity equivalence factors (TEFs) are applied).*

**EPA Position:**

See EPA’s position to LWG’s dispute issue 2c and LSS dispute issue 2.

**Arkema Dispute Issue 3 - Flawed evaluation used to determine whether PTW can be reliably contained**

*There is no scientific support for the assertion that there is NAPL or PTW in the sediments adjacent to the Arkema Site. According to EPA, PTW is a concept used in the NCP to characterize contaminant source material (USEPA 1991). PTWs are those source*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. In the 1991 guidance, EPA stated their expectation that PTW would be treated, wherever practical, because of current technical limitations of long-term reliability of containment technologies. The long-term reliability of containment of certain NAPL PTWs has improved through the development and implementation of reactive capping, as demonstrated by EPA (USEPA 2013).*

*The draft final FS does consider and propose reactive capping but uses a flawed screening analysis to limit its use by designating certain SMAs as PTW NAPL/NRC, reflecting those areas where purported NAPL is deemed not reliably contained (NRC). Furthermore, the draft final FS is not consistent with the EPA guidance on principal threat and low-level threat wastes (LTW) (USEPA 1991), as it does not differentiate PTW from LTW NAPL based on toxicity, mobility, and (realistic) reliability of containment, but uses NAPL and PTW interchangeably. For instance, for shallow areas it states that NAPL or PTW that is not reliably contained within an SMA would be dredged to the lesser of the RAL concentrations or 15 feet.*

*To determine the boundary for where PTW can be reliably contained, two limited capping options were modeled in Appendix D to determine the maximum concentrations of PTW material that would not result in exceedances of AWQC in the sediment cap pore water after a period of 100 years. Contaminants modeled were chlorobenzene, dioxins/furans, DDx, naphthalene, PAHs, and PCBs. Appendix D contains the following errors of commission or omission:*

- The objectives of the analysis are not clearly defined or stated. The document states “this appendix is evaluating whether or not PTW at the Site can be reliably contained under specific assumptions.” What are the assumptions that justify a conclusion that the maximum containable sediment concentrations of chlorobenzene and naphthalene are 320 µg/kg and 140,000 µg/kg, respectively?*
- The two potential active cap designs modeled (thickness of capping layers and amount of active material in cap for a reasonably conservative approach and a more aggressive augmented capping approach) are not representative of the current state of practice for reactive capping and so cannot be used to determine the contaminant concentrations that cannot be reliably contained.*
- The long term reliability of a reactive cap is a direct function of the thickness of the reactive layer and the amendment(s). A more reliable reactive cap with a thickness greater than 12-inches and consisting of a lower layer of organo-clay and an upper layer of GAC should have been considered in Appendix D.*
- Maximum pore water concentration of chlorobenzene used as a continuous source term in the model is based on the relatively old Remedial Investigation (RI) database and is not representative of current conditions, let alone for the next 100 years. In addition, EPA has used data that were not collected pursuant to the RI. EPA has used reconnaissance data collected using a Geoprobe rig. The data are unacceptable for, and cannot be used to represent, pore water chlorobenzene concentrations. Therefore, the maximum pore water concentration EPA used is based on inappropriate data and needs*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*to be replaced in the model. Since the RI data collection, a barrier wall and pump-and-treat system have been installed along the shoreline of the Arkema Site. Furthermore, maximum data are not appropriate for assessing engineering performance, including reliability. A more appropriate input parameter is the 90th percentile concentration.*

*• A range of seepage velocities (0.3, 3, and 30 cm/day) were evaluated, representing the minimum, average, and maximum values measured at the Site. However, actual seepage velocities in SMA 7W are likely lower than 0.3 cm/day due to presence of the barrier wall and pump-and-treat system.*

**EPA Position:**

See EPA's position to LWG's dispute issue 2c and LSS dispute issue 2.

EPA did not establish any boundaries of waste in the 2016 FS. EPA developed estimates of various types of waste to estimate costs in the 2016 FS. The figures show the extent of the evaluation based on various assumptions identified in the 2016 FS report. Boundaries and cap designs will be established in remedial design. EPA agrees that additional data collection will be required to determine the appropriate design and waste treatment and disposition requirements during remedial design.

**Arkema Issue 4 - Inappropriate waste designation for sediments adjacent to the Arkema site**

*The assumed areas for disposal of sediment as RCRA waste (Figure 3.4-35, Attachment Ark-4) are based on a single toxicity characteristic leaching procedure (TCLP) sample for lead and no TCLP samples for chromium. Based on sediment analytical results, the area shown on Figure 3.4-35 does not represent sediment that will require RCRA Subtitle C landfill disposal. The State-listed pesticide residue designation also does not necessarily apply to sediment at the Arkema Site (Figure 3.4-36, Attachment Ark-4). As recently as February 2016, DEQ was researching the issue of whether sediment near Arkema would be designated a State-listed pesticide waste. Item 3 of the "Top 10 State Issues for Proposed Plan" document obtained from the LWG's FOIA request (Attachment Ark-2) states that "Sean needs State determination of State-only pesticide question, which Matt is researching." However, even if it is determined that some portion of the sediment is a State-listed pesticide residue waste, it would not preclude the placement of this sediment in a CDF (see HWIR discussion below) or disposal in a Subtitle D landfill out of state. When a State-listed hazardous waste is transported out of state (for example, to the Roosevelt Regional landfill as presented in the FS), the Oregon State waste designation no longer applies, and the waste can be disposed as a non-hazardous waste so long as it meets other landfill disposal criteria. This was recently demonstrated by the disposal of soil from the Arkema Stormwater and Groundwater SCMs, at the RCRA Subtitle D Roosevelt landfill in Washington.*

*Arkema disagrees with the cost assumption that "cement solidification/stabilization, low temperature thermal desorption, and no treatment will be used in equal proportions to treat pesticide/chlorobenzene PTW" for the disposal of dredged sediment that meets*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*EPA's PTW criteria from the Arkema Site. Notwithstanding the fact that there are no PTW sediments currently identified off the Arkema Site, the FS fails to clearly outline the basis for EPA's assumptions regarding treatment as a prerequisite for offsite disposal. Section 3.2.2.3 fails to clearly identify specific regulations and the conditions under which they are assumed to apply, or not apply, to sediments that are designated as PTW and the mechanism under which they derive need for treatment prior to offsite disposal. Furthermore, the "Top 10 State Issues for Proposed Plan" document obtained from the LWG's FOIA request (Attachment Ark-2) states that "DEQ wants to be clear that land disposal of these sediments does not require treatment under Oregon Administrative Rules." As presented, EPA has arbitrarily made more conservative assumptions for disposal of PTW defined by sediments purportedly containing DDx and NAPL than it has for PCBs, dioxin/furans, and PAHs.*

**EPA Position:**

See EPA position to LSS dispute issue 3.

**Arkema Dispute Issue 5 - Inappropriate application of the Hazardous Waste Identification Requirements (HWIR) Rule for disposal of sediment in a CDF**

*EPA asserts that "Dredged material subject to requirements of a permit that has been issued under Section 404 of the CWA is excluded from the definition of hazardous waste (40 CFR 261.4(g)). This provision is discussed in the Hazardous Waste Identification Rule (HWIR) (63 Federal Register [FR] 65874, 65921; November 30, 1998). Oregon State adopted the HWIR rule in 2003. This rule means that RCRA regulatory requirements do not apply to sediment dredged at the Site and disposed of on-site, such as at the Terminal 4 CDF, if the material otherwise meets the CDF acceptance criteria." (emphasis added)*

*EPA has correctly stated that RCRA regulatory requirements, including the designation of waste sediment as either a Federal or State-only hazardous waste, do not apply to sediment placed in a CDF; however, the statement mischaracterizes the CWA requirement that the sediment must meet CDF acceptance criteria for this rule to apply. This is not the case. Because DEQ has adopted the federal HWIR rule, and the CDF would meet CWA Section 404 requirements, RCRA Subtitle C requirements would not apply, and the dredged material placed in the CDF would not be a hazardous waste. The disposal of Arkema sediment in a Terminal 4 CDF should, therefore, be considered. The failure to consider CDF disposal for Arkema dredged sediment artificially inflates the disposal costs for alternatives related to the dredging at the Arkema Site. EPA disregards the scope and intent of the HWIR Rule by placing arbitrary restrictions on what EPA believes can be placed into the T4 CDF if constructed. All of the EPA's Acceptance Criteria for the T4 CDF are arbitrary and should be removed. Disposal of dredged material should follow the HWIR Rule as adopted by the State. This arbitrary action by EPA has severe negative implications for the FS and any subsequent RA.*

**EPA Position:**

See EPA's position to LSS dispute issue 4.

**Arkema Dispute Issue 6 - Inappropriate use of PCB non-detected values in RAL and PTW footprint maps**

*The RAL and PTW footprint maps incorporate data with high PCB detection limits adjacent to the Arkema Site (Attachment Ark-5). The high PCB non-detects with detection limits 5 times EPA's PTW value (e.g., >1 mg/kg) occurred in the Aroclor analysis as a result of a matrix interference with DDx. The RAL and PTW footprint maps should only consider detected PCBs based on PCB congener concentrations adjacent to the Arkema Site. The identification of PTW and remediation footprints for PCBs adjacent to the Arkema Site based on non-detect values with elevated detection limits resulting from matrix interference with DDx is inconsistent with EPA's PTW guidance and biases the assessment of PTW and remediation footprints for the SDU RM7W alternatives. This exaggerated PCB footprint will also bias the alternative selection for SDU RM7W.*

**EPA Position:**

See EPA's position to LSS dispute issue 6.

**Arkema Dispute Issue 7 - Inaccurate RAL and PTW footprint maps**

*The PCB and PCDD/F RAL and PTW maps were contoured using natural neighbors gridding and did not account for the flow direction or depositional environments in a river system. The RAL and PTW maps in EPA's FS used nearest neighbor interpolation, and data points were inappropriately interpolated through upland areas. An example of this inappropriate interpolation is between points in the Willbridge Terminal and the area between Dock 1 and the Salt Dock on the Arkema Site (Figures 3.4-7, Attachment Ark-5; 3.4-11, Attachment Ark-6). In this example, the points are not correlated and should not be interpolated through the upland portion of the Arkema site. The RAL and PTW maps must include some interpretation to reflect the physical features of the site and site uplands, as well as the hydrodynamics of a river system.*

**EPA's Position:**

See EPA's position to LSS dispute issue 6.

**Arkema Dispute Issue 8 - Background concentrations for PCDD/F compounds in sediment**

*Sediment PRGs for RAO2 and RAO6 as well as riverbank PRGs for RAO9 for the five PCDD/Fs congeners are based on background concentrations. Background PCDD/F concentrations for individual congeners are presented in Appendix B, Table B2-4 of EPA's FS.*

*EPA uses new methods for deriving these levels that appear significantly different from both EPA's methods for other chemicals as well as past LWG input on this subject. Sediment PRGs for RAO2 and RAO6 as well as riverbank PRGs for RAO9 for the five PCDD/Fs congeners are based on background concentrations.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*The background values are based on limited and poor quality data (with elevated detection limits). In fact, only one congener has sufficient data (1,2,3,4,7,8-HxCDF) to calculate a background value and even that is limited (13 of 31 samples were non-detects). Thus, most of the background “values” are based on a 95% UCL of the detection limits. The background values also appear skewed quite low compared to other urban watersheds.*

*The background values estimated based on this limited data and approach, furthermore, are approximately an order of magnitude lower than values from other regions and watersheds. For example, a memorandum published by EPA in 2010 provides a good summary of background levels for dioxins/furans in sediment, which range from approximately 2–5 parts per trillion (ppt) as TEQs. It also summarizes values from Puget Sound which include a TEQ value of 4 ppt for non-urban areas but allowing up to 10 ppt as TEQs for open water disposal; this value is also used in San Francisco Bay and elsewhere.*

*(<https://klamathrestoration.gov/sites/klamathrestoration.gov/files/EPA%20Klamath%20dioxin%20memo%201-13-10%20final.pdf>). The Duwamish Waterway FS establishes an upper bound background value for dioxins/furans as 11.6 ppt TEQ.*

*Background values in other regions and watersheds are expressed as TEQs, which is generally the manner in which cleanup goals for dioxins/furans are expressed. For Portland Harbor, EPA used 5 individual congeners. The individual congener background values provided in Appendix B of the FS and in the PRG tables for RAOs 2 and 6 can be converted to TEQs using TEFs, which results in a value of 0.56 ppt on a TEQ basis (since the 5 congeners equate to the majority of the risk, this value may be slightly biased low, but probably less than 10% of the total TEQ). This background value is an order of magnitude or more lower than the range of values, mainly for non-urban areas, from the literature. A study to better define background levels for dioxins/furans is necessary since the calculated risk-based PRGs are well below even these low-biased background levels resulting in the background values being adopted as the final PRGs. Otherwise, it is unlikely that the remedies for dioxins/furans will be successfully implemented and estimated risk reductions for dioxins/furans will be realized. This latter issue addresses the validity of the alternatives analysis and its biased outcome.*

*It should also be noted that no background values are listed for RAOs 1 or 3. Those PRGs are expressed as TEQs and data is lacking to identify a background level on a TEQ basis. Those PRGs may be below background. In fact, the PRG for RAO3 is four orders of magnitude below the MCL and is likely not reliably measurable at that level. Overall, providing PRGs that are below MCLs is inconsistent with other cleanup actions under CERCLA or other programs. Cleanup to below MCLs is unlikely to be achievable.*

**EPA Position:**

See EPA position to LWG dispute issue 1h and LSS dispute issue 11a.

**Arkema Dispute Issue 9 - Background Concentrations in other COCs and media**

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*The FS (Section 2.2.2.4) states that only sediment background concentrations were estimated and background concentrations for other media could not be calculated due to insufficient data. However, surface water background concentrations were calculated in the RI. Upriver surface water background concentrations of COCs are orders of magnitude higher than the ARARs based on the AWQC. Note, the background UCLs for upriver surface water (dissolved concentrations with outliers removed; Table 7-4b of RI) vs RAO3 AWQC-based PRGs. For example, the background concentrations and ARARs for DDT, PCBs, and TCDD TEQ demonstrate examples of RAOs that are less than background:*

- *background UCL for DDT = 0.000114 µg/L and the ARAR (RAO3) is 0.00002 µg/L;*
- *background UCL for PCBs = 0.000126 µg/L and the ARAR (RAO3) is 0.000006 µg/L;*
- and*
- *background UCL for TCDD TEQ = 0.000126 µg/L and the ARAR (RAO3) is 0.000000033 µg/L.*

*Because of the deficiencies in determining the background levels, a new background study for sediment, surface water and tissue needs to be conducted in the design phase. The results of this evaluation need to be used to update PRGs, RALs and SDUs.*

**EPA Position:**

See EPA's position to LWG dispute issue 1g and LSS dispute issue 11b.

**Arkema Dispute Issue 10 - Benthic risk models do not honor the measured data**

*EPA made extensive changes to the benthic approach for this FS, but those changes are still inconsistent with the comprehensive benthic risk approach contained in the approved BERA. The FS states:*

*“The protection of benthic species to contaminated sediment is evaluated using the benthic risk area defined by an order of magnitude greater than the RAO5 PRGs. The post-construction interim target for RAO5 was established at 50% reduction in the area posing unacceptable benthic risk.” So, instead of using the CBRA, EPA now maps benthic PRG exceedance factors on a point-by-point basis and uses a 10 times exceedance factor to identify areas of concern. EPA then concludes that if 50% of this area is actively remediated, the alternative is “protective” on an interim basis. It is unclear how this new method is: (1) more accurate or consistent with the BERA, or (2) more predictive of benthic risk or the effectiveness of the alternatives, as compared to simply using the CBRAs, which are entirely consistent with the BERA.*

*Furthermore, and most importantly, the benthic risk models used by EPA do not honor the measured data. Although the LRM and FPM are model predictions using data from the toxicity tests conducted with site sediments, much of the measured data is not considered or addressed in this evaluation. Any modeled risk for benthic invertebrates that ignores actually toxicity testing results needs to be assessed in weight-of-evidence and river-mile specific decision-making. The benthic risk footprints should not extend into areas shown to have a lack of toxicity based on actual laboratory toxicity tests. This error has been carried through the alternatives analysis and therefore has biased the selection of alternatives for SMAs in the FS.*

**EPA Position:**

See EPA Position to LWG dispute issue 1b and LSS dispute issue 12.

**Arkema Dispute Issue 11 - Overly prescriptive decision trees**

*The FS acknowledges uncertainties in site characterization and the conservative assumptions used to form the basis for associated technology assignments, however EPA continues to use a prescriptive set of technology evaluation and scoring criteria to determine the technologies to be applied in each area of the site and, with the exception of a vague paragraph in Section 3.8.1, the FS is silent regarding the degree of flexibility that is envisioned to be available during remedial design to refine technology assignments based on the additional information gained through future pre-design investigations. This will lead to a lack of flexibility with regard to technology assignments, depth of removal, potential improvements in technology, design efficiencies to address remedial, and CWA/ESA requirements, among other things.*

*EPA should clearly explain the conditions under which changes to major alternative elements (e.g., changes in technologies assignments, methods to address PTW, methods for determining treatment and disposal requirements, requirements for rigid containment) might be considered or allowed. EPA should explain how new data, including the “initial conditions” assessment, will affect the RAL boundaries based on surface sediment concentrations. The FS should include language to allow for updates to risk assessments. EPA should incorporate decision frameworks for proposing equally or more effective capping options or other technology refinements based on detailed design-level evaluations and new data.*

**EPA Position:**

See EPA’s position to LSS dispute issue 14.

**Arkema Dispute Issue 12 - Prescriptive dredge residuals management strategy**

*The prescribed application of 12-inches of sand across the entire dredge footprint (amended with AquaGate+PAC in areas where PTW present) is poorly supported. The FS is misleading in stating that the placement of sand (and GAC in areas where EPA has speculated that PTW is present) immediately following dredging will eliminate the need for additional dredge passes. The FS indicates that sediment cores would be taken post-placement to verify that thin-layer residual cover successfully reduces residuals concentrations. It is inappropriate to assume a 12-inch layer of residuals management cover will be applied across the entire dredge footprint, without providing a strategy that will determine the necessity for thinlayer placement and flexibility to develop an appropriate thickness.*

*As PAC can be toxic to benthic organisms, overall quantities and where and how it is applied warrants more thoughtful consideration. The FS neglects to consider the physical stability of PAC in the deployment of the thin-layer residuals cover. PAC will be ineffective if it immediately washes away. The FS neglects to consider any possible*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*unintended consequences that may be posed by transport/erosion and aggregation of PAC (with or without adsorbed contamination) in depositional areas. The assumed performance requirements for this residuals strategy are unclear.*

**EPA Position:**

See EPA's position to LSS dispute issue 15.

**Arkema Dispute Issue 13 - Inappropriate use of rigid containment technologies**

*EPA assumes the use of sheet pile barrier walls as dredge water quality control measures based on the suspected presence of NAPL will support the short term effectiveness of all alternatives. The FS still fails to adequately evaluate the implementability, effectiveness, and cost of this particular technology relative to other technologies and BMPs. In making gross assumptions for this FS, EPA has disregarded the complexity of constructing such barrier walls (e.g., consideration of structural components such as king piles and structural bracing, or more complex cofferdam structures) and the associated impacts this will have on numerous aspects of remedy implementation ranging from construction duration (e.g., time required to install walls, and impacts to dredge production rates) to the overall net benefit and cost effectiveness relative to other means. EPA also continues to show figures that depict sheet piling in greater than 50 feet of actual water depth, which is technically infeasible. These figures also imply that sheet piles will be installed in the navigation channel, which would infeasibly obstruct vessel traffic. Sheet pile would also impact ongoing water dependent operations and nearshore fish migration does not evaluate whether sheet piles in the navigation channel could be permitted by USACE.*

**EPA Position:**

See EPA position to LSS dispute issue 16.

**Arkema Dispute Issue 14 - Risk reduction between alternatives**

*The calculated post-construction risks and HI values are higher than the interim target risks and HI. Because much of the remedy relies on MNR, the lack of a residual risk estimation process for time intervals post-construction (up to year 30) limits the usefulness of the residual risk estimates in terms of comparing the protectiveness of the remedies.*

*Furthermore, there is very little difference in net risk reduction between Alternatives B and I for almost all COCs. For most of the COCs, the differences are less than a factor of 2 and sometimes much smaller (e.g., difference in HQ of 0.25). Given the very conservative assumptions that were used to calculate PRGs, differences in estimated risks by a factor of 2 or less are not significant. A more reasonable criterion for evaluating differences in estimated risk between alternatives would be a factor of 10, which should be considered the minimum significant difference given the limited sensitivity of these criteria. A probabilistic-type risk evaluation, which incorporates the quantitative uncertainties, would be a more appropriate approach.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*This small difference in risk reduction between alternative remedy scenarios is likely due to the driving PRGs being based on background. The risk associated with background levels of COCs should be presented in a side-by-side comparison to the residual risk estimates in order to demonstrate the benefit of the remedial measures to the public. Based on the residual risks presented, any remediation beyond Alternative B (which does show a great degree of risk reduction from Alternative A, no action, than the difference between other alternatives) is unwarranted. The very large increase in costs for minimal and insignificant risk reduction between Alternatives B and I is not recognized in the FS.*

*In summary, the removal volumes in Alternative I cannot be justified as a cost-effective reduction of risk in comparison to other alternatives. Nor can the use of mixed criteria such as PRGs (and RALs) from different alternatives (i.e., “E” and “F” applied either site-wide or within an SMA) be justified based on differences in risk outcomes that are within an order-of-magnitude.*

**EPA Position:**

See EPA’s position to LSS dispute issue 8.

**Evraz Dispute Issue 1 - EPA’s Feasibility Study improperly imposes more stringent remedial action levels (RALs) in some areas of the site than others.**

*EPA established a range of RALs based on the distribution of surface sediment contamination. In some areas of the site its preferred alternative (Alternative I) selects “Alternative B+PTW” or Alternative D RALs. However, in other areas of the site, including adjacent to EVRAZ’s Rivergate mill, Alternative I selects “Alternative E” RALs. This leaves higher concentrations of PAHs and dioxins in some portions of the river. There is nothing in the FS that describes why, if the “Alternative B +PTW” or Alternative D RALs are protective in some portions of the river, they are not equally protective in other areas. One specific example where the use of Alternative E RALs drives remedial action to a lower concentration than other areas is the remedial footprint near outfall OF53A. It is unclear why additional risk reduction is necessary at this location. For dioxin, sufficient data is not available to support such a decision. EVRAZ believes the FS is flawed in applying different levels of protectiveness, and that its site should similarly be remediated to “Alternative B+PTW” RALs.*

**EPA Position:**

The SDU specific evaluations for each of the alternatives provides the evaluation of each alternative in various portions of the river (see Section 4 of the 2016 FS). Based on evaluation of how each alternative performed in achieving interim goals and PRGs, some areas achieved those goals in some alternatives, while they were not achieved in other areas. This is due to the variability in the contaminant releases to the Site and the distribution of contamination in sediments in various portions of the Site. However, EPA is applying the same levels of protectiveness everywhere consistently throughout the Site – the interim goals and PRGs are consistent. What is different is the concentration of contamination that needs to be capped or dredged in order to meet those protective levels.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

For Alternative I, Alternative E RALs were selected in SDU 2E to address all PTW and achieve interim targets for all RAOs in this area of the Site.

**Evraz Dispute Issue 2 - Failure of FS to account for riverbank remedial actions already implemented, with EPA's approval.**

*The FS is based on inaccurate information in that it ignores that EVRAZ already implemented a riverbank remedial action for its Rivergate property, a remedial action based on a source control decision made by the Oregon Department of Environmental Quality and concurred with by EPA. Assumed riverbank cleanup extents are used in the overall protectiveness determination and without basis.*

**EPA Position:**

See EPA's position to LWG's dispute issue 1q.

**Evraz Dispute Issue 3 - Inadequacy of "groundwater plume" conclusions.**

*In addition to the concerns raised in the main text of the document, EVRAZ disputes the following issues with respect to EPA's description of what it depicts as a "groundwater plume" adjacent to EVRAZ's Rivergate property.*

- a. For arsenic, this should not be a plume as concentrations in beach groundwater are within the range of or below site background values, do not exceed benthic toxicity criteria and groundwater discharges do not adversely affect the water column.*
- b. For manganese, this should not be a plume at all because it does not include site-specific hardness for ecological values and the basis for the human health PRG is application of tap water Regional Screening Levels (RSLs) for manganese in groundwater. As explained in the main text of the document, RSLs are not appropriate PRGs for groundwater in these circumstances.*
- c. The exposure pathway of concern is in the surface water to which the groundwater discharges. Surface water concentrations here meet the surface water PRG for manganese.*
- d. Groundwater plumes are used in the overall protectiveness evaluation and overestimation of plume extent skews the metrics.*

**EPA Position:**

The 2016 FS identified COCs for groundwater plumes based on information provided by ODEQ. See EPA position to LWG issue 1q.

There has been limited sampling to characterize the nature and extent of the groundwater plumes offshore of the Evraz facility. Further, there have been no source control actions taken at this property to control the groundwater plumes. Contaminants of concern in groundwater are arsenic and manganese based on information provided by ODEQ. [AR Doc # 1469786 and 1469793] Thus, these contaminants will be monitored in pore water during remedial design to ensure that the pore water is not impacted such that a reactive layer in a cap or some other upland control may be necessary to ensure PRGs are achieved. The ecological PRGs for manganese were developed based on site-specific hardness values. [AR Doc # 100005457]

See EPA position to LWG dispute issue 1d, 1m and 1n.

**Gunderson Dispute Issue 1 - Failure to Account for Completed Riverbank Source Control Measures**

*The FS ignores Gunderson's extensive source control work implemented under the oversight of the Oregon Department of Environmental Quality (DEQ) under Voluntary Cleanup Agreement No. WMCVC-NWR-94-01 and Consent Order No. LQVC-NWR-13-02, and in accordance with the requirements set out in the DEQ-EPA Portland Harbor Joint Source Control Strategy (JSCS; DEQ, 2005). Gunderson has implemented permanent riverbank source control measures at some riverbank areas that are identified by EPA as needing remediation. Gunderson has also completed interim source control measures under DEQ oversight at the remainder of the riverbank areas that are identified by EPA in the FS and agreed with DEQ that additional permanent measures will be implemented concurrent with the adjacent in water remedy.*

**EPA Position:**

See EPA Position to LWG dispute issue 1q.

**Gunderson Dispute Issue 2 - "Groundwater Plume" Conclusions Are Inaccurate and Contradictory to Conclusions of the RI**

*The FS depicts two groundwater plumes (referred to herein as the "Southeast Plume" and the "Northwest Plume") adjacent to Area 1 of the Gunderson facility. Gunderson disputes the following issues with respect to the EPA-depicted groundwater plumes.*

*a. EPA provides no clear rationale for depicting the locations and extents of the plumes at the*

*Gunderson facility (and elsewhere in the Portland Harbor).*

*b. During extensive investigations conducted under DEQ oversight, there has never been any evidence that the so-called Southeast Plume exists now, or ever approached anywhere near the river either before or after it was subjected to remediation by sparging.*

*c. The depiction of the Northwest Plume is contradictory to the conclusions of the EPA approved*

*RI, "The data suggest that ongoing migration of the chemicals to the TZW via groundwater discharge does not contribute to significant concentrations of COIs in nearshore TZW sediments."*

*d. The Northwest Plume was delineated because VOC concentrations in near shore TZW exceeded human health screening levels based on the ingestion of Willamette River water. TZW remediation standards based on the consumption of Willamette River water are not appropriate.*

*e. The contaminants detected in a small area of transition zone water have not been detected in surface water.*

*f. The December 2007 Round 3 Groundwater Pathway Assessment Field Sampling Report for Stratigraphic Covering – Gunderson, Prepared for the Lower Willamette Group and submitted to EPA by Integral Consulting concluded that "the stratigraphic*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*information does not indicate a conductive pathway for any remnant TCA plum.... On November 8, 2007, EPA indicated to the LWG Management Team that the agencies concurred that the stratigraphic information did not indicate the need for follow-up TZW sampling."*

*g. The analytical data that serve as the apparent basis for EPA's delineation of the Northwest Plume were collected more than ten years ago. VOCs in upland groundwater have exhibited long-term decreasing trends, even prior to active treatment, which began in 2007. Based on these trends and the low residual concentrations of VOCs in groundwater, DEQ authorized deactivation of the groundwater treatment system for this plume in 2014. There is no evidence that it posed any current threat to sediments or porewater.*

**EPA Position:**

Groundwater plumes were identified in the RI Report, Section 4 and Appendix C2 (see Figure 4.4-10a-c, Map 4.4-3a-h, and Table 4.2-2). There has been limited sampling to characterize the nature and extent of the groundwater plumes offshore of the Gunderson property. Further, there have been limited source control actions taken at this property to control the groundwater plumes. Contaminants of concern will be monitored for in remedial design to determine whether the pore water is impacted such that a reactive layer in a cap or some other upland control may be necessary to ensure PRGs are achieved.

See EPA position to LWG dispute issue 1d, 1m and 1n.

**NW Natural Dispute Issue**

*On September 27, 2012, EPA provided a preliminary set of comments on the Gasco EE/CA stating that "any comments provided on the Gasco EE/CA are preliminary as the Gasco EE/CA is so heavily dependent on the Portland Harbor draft FS.... Therefore, comments provided on the Portland Harbor draft FS may also need to be addressed in the Gasco EE/CA." Pursuant to EPA's February 4, 2016 agreement with the Lower Willamette Group, EPA is finalizing the Portland Harbor FS rather than providing comments. Many of the modifications EPA has made in the June 2016 FS are inconsistent with the terms of the Gasco Consent Order and with the information, analyses and conclusions of the Gasco EE/CA.*

**EPA Position:**

The effect of the 2016 FS on the Gasco Consent Order is beyond the scope of this dispute.

**NW Natural Dispute Issue 1 - Risk Reduction and Risk Management**

*In the September 9, 2009 Administrative Settlement and Agreement and Order on Consent for the Gasco Sediments Site (the "Gasco Consent Order"), EPA and NW Natural specifically agreed to use risk management principles and the results of the*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*harborwide risk assessment to define areas for and approaches to cleanup that are based on significant risk reduction.*

*“This SOW’s goal is to design a remedy consistent with the ROD that will reduce key human and ecological risks cost effectively given Site characteristics, which results in a cleanup that is protective of public health and the environment and meets all federal and state applicable and relevant and appropriate requirements (ARARs). The risk lines of evidence used in the ROD will guide risk management for the Gasco Sediments Site. The design will also use a risk management framework consistent with EPA guidance (EPA 2005 and EPA 1988) on developing sediment remedies and specifically recognizes the risk management goals for the project throughout the evaluation and design process. The risk management related approaches that are specifically important to this project and are consistent with guidance include:*

- The Gasco Sediments Site cleanup boundary will be consistent with Portland Harbor EPA approved BLRA.*
- Evaluate remedial alternatives with regard to total net risk reduction within the overall framework of the NCP remedy selection criteria.*
- Use the Portland Harbor risk assessment protocols, procedures, data, and outcomes whenever possible to set clean up boundaries and evaluate risk reduction, unless use of these would cause an unacceptable delay to the Gasco Sediments Site remediation.”<sup>57</sup>*

*As more fully described in the LWG’s comments on the EPA August 2015 draft FS and the main text of this document, EPA’s FS is not consistent with either the approved baseline risk assessments for Portland Harbor or a risk management approach focused on the reduction of key human and ecological risks at the site. In particular, NW Natural objects to EPA’s use of TPAH RALs and PRGs, the use of which are inconsistent with the findings of the approved BHHRA and BERA, are technically unsupported, and result in significant mass removal unrelated to any measurable reduction in risk.*

*cPAH PRGs and RALs (expressed as BaPEq) were developed under EPA oversight for the LWG’s March 2012 draft FS and were used in NW Natural’s March 2012 draft Engineering Evaluation and Cost Analysis for the Gasco Sediments Site (the “Gasco EE/CA”). BaPEq is consistent with the methods and results of the Portland Harbor BHHRA, which were assessed in terms of total cancer risk from cPAHs on a BaPEq basis. The risk-based approach called for in the guidance<sup>6</sup> specifies that RALs should be consistent with the methods and findings of the BLRAs to ensure that sediment remedies are “risk-based” (i.e., result in effective risk reduction).*

*The EPA June 2016 FS itself is consistent with this and expresses all human health PAH PRGs as BaPEq. Therefore, use of BaPEq RALs clearly allows for a direct comparison on a consistent basis between the RALs and the PRGs. Using TPAH RALs does not allow for a direct relationship between RALs and PRGs. In fact, using a TPAH PEC for protection of benthic exposure is not only inconsistent with the approved BERA but is particularly inappropriate for the Gasco sediments site, where NW Natural has invested considerable effort and expense (under EPA oversight) in evaluating the multiple lines of*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*evidence approach defined in the Gasco Consent Order as the basis for identifying areas requiring active remediation consistent with the BLRAs.*<sup>58</sup>

*NW Natural further objects to the application of TPAH (or BaPEq) RALs within the navigation channel. cPAH risks related to sediment direct contact and shellfish consumption exposures occur only outside the navigation channel (along the shoreline), and as a result, BaPEq RALs associated with these potential risks should be applied in exposure pathway areas only. Although some potentially unacceptable cPAH risk from fish consumption was identified in the BHHRA, EPA was unable to develop any valid relationship between cPAH fish tissue and sediment concentrations at the Site, or any other sediments site, due to the rapid metabolism of PAHs by vertebrate fish.*<sup>59</sup> *Carcinogenic PAHs represent less than 1% of the cumulative risks to people eating fish and are, therefore, not a technically valid reason to significantly expand the remedy on the basis of a technically inappropriate PRG, given that there is no reasonable expectation that such an expansion could have any meaningful impact at all on the overall fish consumption risk. It is critical to note that if the shellfish consumption PRG EPA has proposed to use as a surrogate for fish consumption were applied at the same fish exposure scale as EPA used in the BHHRA (whole river mile rather than one-third transect river mile), all remedial alternatives (other than no action) evaluated in the Gasco EE/CA would attain the PRG without application of TPAH or BaPEq RALs in the navigation channel.*

*TPAH or BaPEq RALs can only be linked to effective risk reduction along the shoreline (using the BHHRA findings and the resulting appropriate PRGs for sediment direct contact and shellfish consumption). If inappropriately applied to the navigation channel, where the risk pathway does not exist, the remedy would cost perhaps hundreds of millions of dollars more, yet result in no additional risk reduction. These RALs should therefore only be used only along the shoreline outside of the navigation channel where the exposure pathway is complete. The multiple lines of evidence (LWG Comprehensive Benthic Risk Area) approach outlined in the Gasco Consent Order and consistent with the BERA is appropriate for protection of ecological receptors and NW Natural respectfully requests that it be used by EPA for remedial decisions in that area.*

**EPA Position:**

See EPA position to LWG dispute issue 1d.

**NW Natural Dispute Issue 2 - Future Source Material**

*EPA's identification of "globules or blebs" of NAPL as "source material" constituting "principal threat waste" (PTW) at the Gasco Sediments Site is inconsistent with the more specific definition of "potential future source of risk material" in Section 3.2 (RAO 1) of the*

*Gasco Consent Order Statement of Work through the delineation of "substantial product."*

*Section 3.6.2.1 of the Gasco SOW states:*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*“Areas with substantial presence of product in sediments is a line of evidence related to potential mobility of chemicals in the future, and thus related to risks identified in the BLRA. Visual observations in sediment cores shall be the primary parameter used for this line of evidence. As noted above, the term “substantial” product is intended to 1) target product that is related to potential future mobility and 2) indicate a preference for removal as defined by RAO #1. The definition of substantial product does not include every incidence of product observation at the site.”*

*Section 3.6.2.1 goes on to provide more than a page of detail on the precise physical characteristics of material that EPA will consider sufficiently mobile to constitute source material. Based upon this definition, NW Natural has conducted multiple field investigations at a cost of several million dollars to delineate the location of “substantial product” at the Gasco sediment site. These investigations were used to complete detailed and site-specific remedial alternative evaluations in the Gasco EE/CA.*

*The June 2016 FS does not explain why EPA has apparently abandoned the more specific and technical definition of “substantial product” in favor of “globules and blebs” or why “globules and blebs” is a superior approach for identifying material that presents a significant source of future risk. In the absence of any technical justification, and given the substantial resources NW Natural has put into complying with EPA’s original direction on the identification of potential future source material, EPA’s change of course is arbitrary and capricious.*

*NW Natural respectfully requests that EPA abide by the more specific and technically sound definition of “substantial product” contained in the Gasco Consent Order.*

**EPA Position:**

The NCP and EPA guidance uses the terms “source material” and “principal threat waste”, not “substantial product.” Any material that is highly mobile as analyzed in the 2016 FS is principal threat waste. It is expected that substantial product as defined in the Gasco order matches up with and is consistent with the highly mobile PTW identified in the 2016 FS. The 2016 FS is being consistent with the NCP and EPA guidance.

**NW Natural Dispute Issue 3 - Remediation Waste**

*EPA’s June 2016 FS identifies a category of remediation waste called “Waste or Media Containing Waste that May Warrant Additional Management.” EPA states that “Waste with this designation may be specially managed as a non-hazardous waste at a Subtitle C facility based on the exceedance of TCLP criteria for MGP-related constituents and/or special considerations such as worker safety and equipment decontamination. However, if the material is treated and TCLP criteria are no longer exceeded after treatment, it may be disposed of in a RCRA Subtitle D facility.”*

*NW Natural agrees that MGP-related remediation waste that exceeds TCLP criteria at the time it leaves the site will be disposed of as non-hazardous waste at a Subtitle C facility. This material is identified as “Special Waste” under the Gasco Consent Order.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*To the extent, however, that EPA's June 2016 FS indicates that it may require MGP-related remediation wastes that do not exceed TCLP criteria to be disposed of at a Subtitle C facility based on other "special considerations," that requirement would be inconsistent with the Gasco Consent Order, which provides*

*"The method to determine that MGP-related material should be managed as a Special Waste shall be based on the absence of TCE and associated CVOC chemicals and exceedance of TCLP criteria for any MGP-related constituent. If TCLP criteria are exceeded at the time the material leaves the Site, then the material shall be designated Special Waste and transported to a Subtitle C facility. If not, the material would be disposed of as Cleanup Material at a Subtitle D facility [permitted to accept the material]."*

*This method applies to both untreated and post treatment materials, if treatment is proposed. Consequently, an untreated material may meet this definition, but, upon treatment may be determined to no longer meet this definition. In the event that treatment, including treatment in barges, changes the definition, the material would no longer be designated a Special Waste."*

*The June 2016 FS goes on to state that EPA is assuming "for FS cost purposes" that Gasco remediation wastes identified as PTW "would exceed the TCLP criteria and would need cementbased solidification treatment prior to disposal in a Subtitle C disposal facility."*

*NW Natural respectfully requests that EPA clarify that, consistent with the Gasco Consent Order (and text earlier in the same paragraph in the June 2016 FS), material that either does not exceed TCLP criteria or that is treated so that TCLP criteria are not exceeded may be disposed of in an appropriately permitted Subtitle D facility.*

**EPA Position:**

EPA's 2016 FS was clear what the assumptions were about disposal of MGP wastes and the need for treatment, and that if TCLP criteria are no longer exceeded after treatment then dredged MGP wastes could be disposed of in a RCRA Subtitle D facility. The 2016 FS page 3-29 stated:

**Waste or Media Containing Waste that May Warrant Additional Management**

MGP wastes are by definition not RCRA hazardous wastes per 40 CFR §261.24(a), which specifically excludes solid MGP waste. While MGP wastes are exempted as a RCRA hazardous waste, concerns about the toxicity and mobility of the material prompted EPA to classify these materials as a "Waste or Media containing Waste that May Warrant Additional Management" at the Site so the contaminated sediment could be appropriately handled and managed. Waste with this designation may be specially managed as a non-hazardous waste at a Subtitle C facility based on the exceedance of TCLP criteria for MGP-related constituents and/or special considerations such as worker safety and equipment decontamination (USEPA 2004, 2005). **However, if the material**

**is treated and TCLP criteria are no longer exceeded after treatment, it may be disposed of in a RCRA Subtitle D facility.** It was assumed for FS cost purposes that the MGP waste identified as PTW NAPL/NRC at the Gasco former MGP facility would exceed the TCLP criteria and would need cement-based solidification treatment prior to disposal in a Subtitle C disposal facility. (emphasis added)

**NW Natural Dispute Issue 4 - Site-Specific Technology Assignment and Evaluation**

*The Gasco Consent Order provides for evaluation of “a range of technologies including dredging, capping, and Monitored Natural Recovery (MNR). Alternatives will include combinations of technologies that are tailored to the physical, chemical and other conditions of the Site.” By contrast, the EPA June 2016 FS assigns prescriptive technologies based upon generalized decision trees. The EPA alternatives do not allow evaluation of the comparative effectiveness of various combinations of technologies applied within the same area of the site – the only difference among the EPA FS alternatives is the size of a single applied technology.*

*The combination of technologies that will attain the best balance of risk reduction and cost effectiveness at any specific location is highly site-specific. EPA’s remedy selection must allow for technology adjustment and refinement through the incorporation of the types of site-specific information considered in the Gasco EE/CA but not carried forward into EPA’s June*

*2016 FS. EPA has not provided any rationale for its decision not to import the more refined technology evaluations of the Gasco EE/CA into the FS (or into the Proposed Plan, for that matter). EPA should, at a minimum, clarify how technology assignments will be refined and adjusted during remedial design and implementation. The draft capping demonstration decision tree EPA provided to NW Natural in November 2015, for example, would be an appropriate sort of tool to illustrate how EPA intends to make refinements based on site-specific data or other remedial design information. EPA’s decision not to incorporate such tools into the June 2016 FS or the Proposed Plan is a major contributor to our inability to understand EPA’s vision for how cleanup will actually be designed and implemented, especially if additional data collection leads to a change in our understanding of site conditions.*

*NW Natural also objects to EPA’s decision to assign remedial technologies at Gasco that ignore the documented performance of the upland hydraulic control & containment system installed under Oregon DEQ oversight and in close coordination with EPA. Similarly, the June 2016 FS provide does not discuss or consider the integration of HC&C system performance data in the future during remedial design.*

*The Gasco Consent Order clearly states that “cleanup alternatives shall be evaluated in the context of upland groundwater source controls, which will be implemented by this time, including [ ] reviewing groundwater seepage rate reductions as measured or predicted for upland source control performance[; a]pply the most up to date estimates of groundwater seepage rates and chemical concentrations (as measured or extrapolated) for evaluation of attenuation (i.e, MNR), capping, and dredging*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*alternatives and their long term effectiveness[; and e]valuating attenuation rate predictions for groundwater and TZW that will not be directly remediated by upland source controls.” EPA’s unexplained retreat from a site-specific, technically sound decision framework that directly accounts for the performance of upland source controls to a generic approach that ignores established fact is arbitrary and inconsistent with the Gasco Consent Order. NW Natural respectfully requests that EPA state that technology assignments can be reevaluated during design in a manner that includes comparative effectiveness using site specific data and procedures consistent with the Gasco Consent Order (as was done in the Gasco EE/CA), including current conditions associated with existing upland groundwater source controls.*

**EPA Position:**

As described in Section 3 of the 2016 FS, technology assignments were made based on environmental and anthropogenic conditions at the Site. The entire Portland Harbor Site (2,167 acres) exceeds PRGs and thus requires action. The four general response actions for consideration in the 2016 FS are capping, dredging, enhanced natural recovery (ENR), and monitored natural recovery (MNR) which is consistent with the technologies listed in the Gasco order. ENR and MNR (per EPA’s 2005 Contaminated Sediment guidance) are most appropriately applied to low contaminant concentrations in large diffuse areas since:

- harm to the ecological community due to sediment disturbance may outweigh the risk reduction of an active cleanup
- slow in reducing risks in comparison to active remedies
- includes some risk of reexposure of the contaminants
- the time frame for natural recovery may be slower than that predicted for dredging or in-situ capping
- relies upon institutional controls, such as fish consumption advisories, to control human exposure during the recovery period, which may have limited effectiveness

Therefore, ENR and MNR were assigned to areas not addressed through capping and dredging since the Site will naturally recover once the higher concentration areas are addressed. The 2016 FS did not assign ENR in the main channel since the CSM is that this is a transitional river system where both deposition and erosion occur seasonally. Therefore, any sand placed in this area would be transported downriver and would not enhance the natural recovery in the area where it was placed. EPA identified Swan Island Lagoon as an area where ENR would be applied; however, there may be some opportunities in offshore areas (coves, embayments, slips) where ENR may be used to ensure PRGs are achieved, which can be explored in remedial design. These technology assignments are generally consistent with the LWG 2012 draft FS, although the LWG’s 2012 draft FS assigned in-situ treatment within SMAs which EPA determined not be supported by the empirical evidence of the erosive conditions in many areas of the site (see EPA’s comments 70 through 74 on the LWG’s 2012 draft FS). **[AR Doc # 100007297 through 100007299]**

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

The navigation channel and future maintenance dredge areas were assigned dredging technology within sediment management areas (SMAs) since these areas are slated to be dredged in the future and therefore placement of a cap would prevent that activity (future dredging) in that area of the Site. This technology assignment is consistent with the LWG 2012 draft FS.

Caps were assigned under structures that would not be removed during remedial action. However, dredging with specialized equipment can be conducted under some types of structures. The decisions to remove a structure, dredge under a structure, or cap design will be made in remedial design.

In the shallow zone (which includes river banks), EPA applied a dredge/cap technology assignment within SMAs based on habitat issues and 404(b)(1) requirements. The amount of dredging and capping and the cap design used in this area is to be determined in remedial design. EPA made reasonable assumptions in the 2016 FS in order to develop a cost estimate.

The assignment of technologies within SMAs in the intermediate zone (the area between the navigation channel/FMD zone and the shallow zone) are discussed in Section 3.4.6 and Appendix C of the 2016 FS. Factors evaluated included current and reasonably anticipated future land and waterway use, areas of erosion/deposition, sediment bed slope, infrastructure such as docks and piers, and physical sediment characteristics. If both capping and dredging technologies were both found to work in a particular area of the Site, EPA applied the capping technology.

In-situ treatment was included as components of ENR, capping and dredge residual management in various areas of the river to address contaminated groundwater plumes and principal threat waste remaining in the river. Ex-situ treatment was also assumed as a component of disposing of certain dredge material. Several assumptions were made to develop costs in the FS regarding in-situ and ex-situ treatment of material for cost purposes, but the application and extent of treatment will be determined in remedial design.

Therefore, EPA did evaluate all available technologies to specific areas in development of the alternatives and selected the appropriate technology to use based on site-specific environmental and anthropogenic conditions. EPA's 2005 Contaminated Sediment guidance acknowledges that alternatives are combinations of technologies since single technologies do not work in a large complex river system with varied uses. [2016 FS, Section 3.1.1]

The decision trees in the 2016 FS merely presented these decisions and the assumptions used to develop the cost estimates and are not meant to imply prescriptive actions to be carried out in remedy implementation.

**TOC Holdings Dispute Issue 1**

*The June 2016 FS neglects to include a discussion of upland source controls that have been implemented and the performance of those source controls in the remedial evaluations. The Time Oil groundwater plume identified in section 1.2.3.4 is fully controlled and meets JSCS values for all constituents other than potentially arsenic, which does not appear to be associated with site-related groundwater contamination.*

**EPA Position:**

The purpose of the FS is to develop and evaluate remedial alternatives for the in-river portion of the Portland Harbor site. EPA is not making a cleanup decision on upland sources and therefore it was appropriate that the 2016 FS did not evaluate or discuss specifics about source control measures that have been taken. Prior to implementing the cleanup, the effectiveness of relevant source control actions will be evaluated to minimize the risk of recontamination. The 2016 FS assumed that all sources were controlled in evaluating and comparing the remedial alternatives' performance to each other. However, the 2016 FS acknowledges that there are some areas where the contamination (usually groundwater and subsurface sediment) extends beyond the point of upland control in which a reactive layer may be needed to ensure that PRGs will be attained in pore water. If PRGs are already attained, then a reactive layer will not be necessary. The 2016 FS identifies where known groundwater plumes throughout the Site are located and the contaminants of concern so that in remedial design focused pore water sampling can be conducted to determine the appropriate cap design or residual management layer to employ.

**TOC Holdings Dispute Issue 2**

*EPA's application of E RALs in some but not all parts of SDU 3.5E results in the identification of a Sediment Management Area for PeCDD where the current SDU 3.5 SWAC already meets the most conservative PeCDD PRG of 0.0002 ppb for RAO2 (fish consumption on a river mile basis).<sup>71</sup> Therefore, no sediment remedy is necessary to achieve RAO2 in the relevant exposure area.*

**EPA Position:**

The RALs are applied to all parts of the Site and therefore all parts of SDU 3.5E. The RALs for an alternative are used in combination, not individually, to delineate areas to apply the remedial technologies of capping and dredging. If a contaminant concentration for one of the RALs is not exceeded in a particular part of the river, then that RAL is not applied. RALs are applied on a point-by-point basis, but evaluations of the effectiveness of the RAL achieving PRGs is conducted on broader spatial scales consistent with the baseline risk assessments. The evaluation is made on all contaminants posing risk, not individually.

Respondent is correct that the most conservative sediment PRG for 1,2,3,7,8-PeCDD is 0.0002 µg/kg for RAO 2. In review of Figure 3.4-10, which presents the 1,2,3,7,8-PeCDD RAL contours, the same RAL is used for Alternatives D, E, F and G of 0.0008 µg/kg, which is only a factor of 4 greater than the PRG. The pre-remedial SWAC in SDU

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

3.5E for 1,2,3,7,8-PeCDD is 0.00025 µg/kg (Alternative A) and the post remedial SWAC for Alternative E is 0.000048 µg/kg (see Table J2.3-7). Since the pre-remedial SWAC is greater than the PRG, a sediment remedy is necessary to achieve RAO 2 in the relevant exposure area. Further, the evaluation in the 2016 FS is based on a limited number of samples (19 sample locations) and additional sampling would need to be conducted to determine the extent of the contamination. A decision in remedial design based on additional sampling will have to be made as to whether or not the area warrants action.

**UPRR Dispute Issue**

*The FS preferred alternative identifies two areas of sediments between RM 10 and 11 that EPA has identified for cleanup, purportedly due to exceedances of the PCB remedial action level (“RAL”). EPA also identified these areas on Figure 3.2-3 as containing principal threat waste. This area of the Site is near Union Pacific’s railyard at Albina Yard. Union Pacific disputes this determination, particularly the area from approximately RM 10.7 to RM 11 where there are no exceedances of the applicable RAL in surface or subsurface samples of sediments.*

*EPA’s potential cleanup area near RM 10.7 appears to be based on a PCB exceedance in soil at one location on a 900-foot stretch of the riverbank. EPA included riverbanks as part of its draft FS evaluation of alternatives, but did not identify Albina Yard as a site with “known contaminated riverbank” in section 1.2.3.5 of the FS.*

*Moreover, in its Final Remedial Investigation/Source Control Measures Evaluation Report for Albina Yard dated November 2010, which was reviewed and approved by Oregon DEQ, Union Pacific determined that the riverbank near Albina Yard had a low potential for erosion because it was highly vegetated and stabilized with rock/rip rap. Because PCB concentrations in the sediments are below the applicable RAL, and the riverbank is stable, this area of sediments should not be included as a potential cleanup area. Certainly, the FS contains no explanation for this area’s inclusion as a potential cleanup area, much less as an area containing principal threat waste.*

**EPA Position:**

See EPA’s position to UPRR’s dispute issue 6.

**III. LSS, Inc. (on behalf of Arkema, Inc.) DISPUTE STATEMENT RESPONSE**

**LSS Dispute Issue 1 - Inadequate Conceptual Site Model**

*EPA’s inadequate conceptual site model (CSM) does not provide an adequate foundation for a thoughtful comparative evaluation of alternatives. The FS does not sufficiently describe the relevant site features, baseline risks, sources, chemical fate and transport, site uses, and other important factors necessary to understand the potential cost effectiveness of EPA’s remedial alternatives. Information on contaminant fate and transport is not provided in EPA’s CSM discussion. In addition, the site has been characterized by EPA based on aggregated sediment data (i.e., sediment data collected over more than a decade) without regard to time-dependent changes operating in this*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*system. It is not possible to effectively evaluate remedial alternatives without a robust CSM of the site.*

*Some examples of specific technical issues with the CSM presented in EPA's FS report include the following:*

*Aggregating sediment data from the late 1990s through 2007 for the purpose of performing a sediment surface characterization. This is a fatal flaw in EPA's analysis as it prevents any signal of dynamic conditions from being observed; this is also an essential component of monitored natural recovery (MNR) that EPA has included as an important element of every alternative.*

**EPA Position:**

See EPA's position to LWG's dispute issue 1d and 2a.

*Assuming without evidence, and ignoring subsequent evidence to the contrary (including 2012 fish tissue, 2013 sediment profile imaging [SPI] data and 2014 sediment data) that the sediment surface conditions at this site are at steady state. The Portland Harbor site is clearly a dynamic system. This is a fatal flaw in the CSM.*

**EPA Position:**

The CSM in the RI Report produced by the LWG and approved by EPA describes the lower Willamette River as a dynamic river system (see Portland Harbor RI, Sections 3 and 10). EPA's assumption was that the Site is in dynamic equilibrium, not steady state. EPA did consider the 2012 fish tissue data as a line of evidence for MNR (see 2016 FS Section 3.6.1.3). EPA only considered data collected under EPA approved work plans; the 2013 sediment profile imaging [SPI] data and 2014 sediment data were not collected under an EPA approved work plan.

*Ignoring subsurface conditions where geochemistry and microbiology are key parameters associated with the natural recovery of several constituents for which EPA deems remediation a requirement. We know many areas of this site are under reducing conditions based on the presence of methane in cores. Reductive dehalogenation is a known pathway for natural recovery for some chlorinated compounds. In situ processes of natural recovery should have been addressed in the CSM and the FS. This is particularly important as a consideration for active remediation areas determined by EPA to be located landward of the pier-head line at the Portland Harbor site.*

**EPA Position:**

EPA used the data collected by the LWG to draft the 2016 FS. The LWG did not evaluate groundwater plumes at the Site. As stated in the 2016 FS, the extent of groundwater plumes discharging to the river is currently unknown. Further, the effects of source control on groundwater plumes is unknown because EPA has not been provided any performance data. Information regarding the extent and degradation of groundwater

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

plumes in the river will be considered in remedial design to ensure that adequate caps are placed in the river to deal with residual groundwater plumes, where necessary.

*It is unclear if the sitewide total PCB spatially weighted average concentration (SWAC) values presented in EPA's FS included the RM 11.2 information acquired during the Supplemental RI performed in Segment 1 (River miles 9 to 11.7). This creates a significant problem in the comparison of subsequent surface SWACs because it suggests site conditions at the time of the RI were actually cleaner than they were. This makes the demonstration of significant sitewide natural recovery more difficult and inaccurate.*

**EPA Position:**

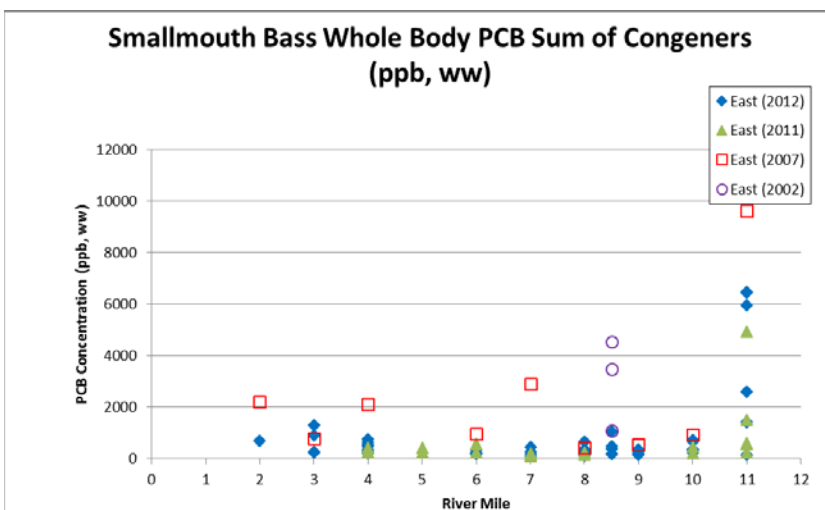

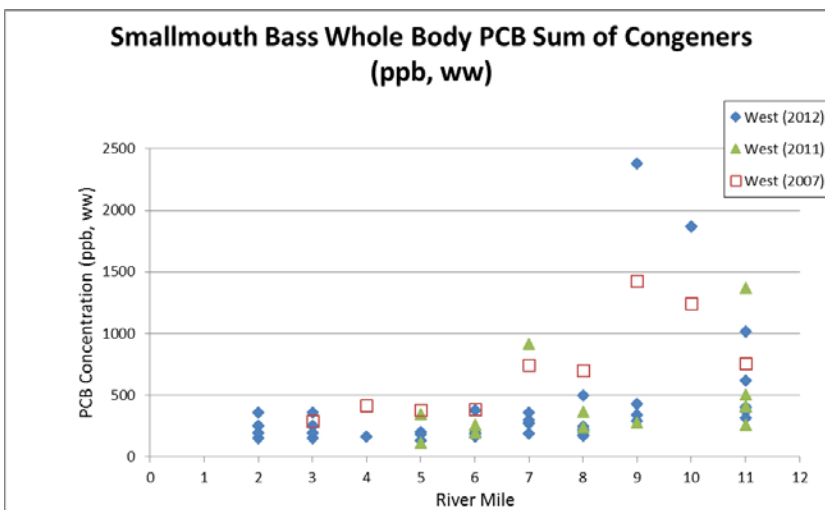

The 2016 FS clearly states in Section 1.3 that the data collected by the RM 11E Group were not included in the FS database. EPA reviewed the data prior to making the decision not to include in the database (although it is in the administrative record because EPA considered it) and determined that it would not significantly change the remedial footprints. EPA is unclear why the Respondent believes that the omission of this data would result in a significantly different SWAC since the data were collected to supplement the RI/FS data, not to recharacterize this area of the Site. EPA did not look at natural recovery Site-wide as the river dynamics are not consistent throughout the Site. EPA looked at natural recovery on a smaller spatial scale as discussed in Appendix D8 of the 2016 FS.

*The use of highly uncertain SWAC values (in some cases the SWAC values varied by an order of magnitude) in localized segments of the site to establish predicted tissue concentrations. This indicates a significant scale effect associated with the surface data used to support the CSM that indicate a lack of characterization in "extent" in the near field of EPA's CSM.*

**EPA Position:**

The variation in the SWAC values in localized segments of the Site does not mean that the SWAC values are highly uncertain. It has to do with the variability in the sediment data and translates into the variability in the fish data. The smallmouth bass data collected in 2007, 2011 and 2012 all show that fish concentrations vary throughout the Site, as can be seen by the plots of the data in the following two figures.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Evaluating the SWACs on this spatial scale (1 RM) reflects the home range of the fish; thus, accurately predicts the exposure to the fish species from contamination in those areas of the Site, and are more representative of the effects of the cleanup in those areas.

*A flawed approach was used for calculating site background concentrations (see dispute issue 11 below).*

**EPA Position:**

See EPA’s position to LSS’s dispute issue 11, below.

*A robust surface sediment data set that is representative of current conditions is critical for setting up initial conditions for the alternatives evaluated in the FS. EPA’s FS uses aggregated sediment data from 1997 through 2007 for the surface sediment characterization. When these outdated data are used to define surface sediment concentrations at the site, it shifts the “knee of the curve” for comparing alternatives away from the alternatives with less active remediation (B, C, and D) and toward*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*alternatives with more active remediation (E, F, G, and I). Graphs of PCB sitewide SWAC versus duration for EPA's FS SWAC (84 µg/kg) and the SWAC based on the recent 2014 sediment data (40 µg/kg) are presented in Exhibit 1. CSM errors and omissions need to be corrected to properly understand the source, distribution, fate, and transport of site COCs and to accurately assess and weigh the differences between remedial alternatives.*

**EPA Position:**

EPA used a robust data set provided by the LWG under EPA oversight to develop the alternatives in the 2016 FS. The data set includes 2,293 surface sediment samples collected during the RI to characterize the baseline of the Site. The 2014 data set was not collected under an EPA approved work plan and the validity of the data is uncertain. Further, the 2014 data set is based on merely 98 samples, which is not comparable to the FS data set and can be misleading. [See pages 6 and 7 in **AR Doc ID # 100033508.**] As can be seen from these figures, the data collected in 2014 does not represent the distribution of contamination in the Site and development of RAL curves using that data apportion low level concentrations to large areas of the Site that have greater concentrations. EPA does not believe there are any errors or omissions in the CSM and that the information used in the 2016 FS is sufficient to develop and select a remedial alternative. EPA acknowledges that additional baseline sampling will be needed during remedial design to implement the remedy and apply the decision tree.

**LSS Dispute Issue 2 - Principal Threat Waste Adjacent to the Arkema Site**

*EPA inappropriately identifies chemicals in sediment adjacent to the Arkema Site as PTW based on either a "source material," "not reliably contained," or "highly toxic criterion. As expanded upon below, source material has never been identified in Arkema Site sediment; EPA should not identify chemicals that can be reliably contained as PTW; and chemicals that require long-term exposure durations through indirect exposure pathways (i.e., consumption of fish tissue) should not be identified as "highly toxic." In addition, the blanket identification of large areas with low concentrations of chemicals in sediments as PTW is neither required by the National Contingency Plan (NCP) nor necessary to protect public health or the environment.*

*EPA errs when it misidentifies source material in the FS based on "globules or blebs of product in surface and subsurface sediments...." and when it states "NAPL observed in sediment cores offshore of Arkema contains chlorobenzene and DDT (dissolved)." Arkema/LSS disputes the presence of NAPL globules and blebs related to the site or historical site operations (i.e., sheens related to oils and other uses of the river by ships and other vessels are not related to Arkema and would not contain Arkema contaminants such as MCB). Arkema/LSS responded to CDM Smith's 2013 memorandum (Exhibit 2) that purports to identify NAPL at the Arkema site. To resolve the issue, Arkema prepared a work plan in response to EPA requests under the EE/CA Administrative Order on Consent (AOC) to yet again confirm that NAPL was not present in sediment adjacent to the Arkema site (Integral 2016, Exhibit 3). In addition, no samples of NAPL offshore of Arkema have identified an MCB NAPL. There is no data that supports EPA's statement*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*that NAPL observed in Arkema sediment "...contains chlorobenzene....". Significantly, a document titled "Top 10 State Issues for Proposed Plan" obtained from the LWG's Freedom of Information Act (FOIA) request identified that based on Oregon DEQ's review of the data "The multiple phases of sediment investigation have not encountered sediment exhibiting NAPL saturated conditions that would warrant thermal treatment prior to management." The status column for the same issue states that "EPA agreed to not assume NAPL at Arkema for the purposes of the cost estimate" (Exhibit 4). Based on these records, we conclude that EPA and DEQ agreed that there was no MCB NAPL in offshore sediments, and therefore the assertion that such sediments represent PTW Source Material as defined by EPA's PTW fact sheet is without foundation, acceptance, or support.*

*EPA erred when it identified an extensive area of groundwater containing MCB DNAPL discharging to the river as "not reliably contained" (Exhibit 5). First, there is no documented MCB DNAPL groundwater plume to the extent shown in EPA's Figure 3.2-4, adjacent to the Arkema site. The nature and extent of MCB DNAPL in groundwater or sediment porewater as shown in this figure is not based on any current site data. Second, groundwater SCMs have been implemented at the site beginning in 2012, including an upland groundwater barrier wall and extraction and treatment system. The groundwater pathway to the river from upland areas that have MCB in groundwater has been cut off and containment has been in existence for 4 years, and therefore, there is no ongoing source of dissolved phase MCB to the sediment adjacent to the Arkema site. There is no scientific evidence that supports the existence of an ongoing source of MCB DNAPL to the sediment adjacent to the Arkema Site. Groundwater and porewater sampling conducted after the implementation of the SCM has not identified a MCB DNAPL source to sediment adjacent to the Arkema Site. The site characterization error which postulates an extensive area of chlorobenzene DNAPL in sediment at the Arkema Site biases the assessment and comparison of the effectiveness of alternatives as evidenced from the following text: "Alternative D has less capped area (71 acres), but does not reliably contain all PTW remaining in the river." (USEPA 2016, p. ES-15). Without an accurate assessment of NAPL, PTW and PTW areas, EPA's alternatives evaluation is highly inaccurate.*

*EPA errs when it misidentifies the remaining areas of the Arkema site (including areas upstream and downstream of Arkema; Exhibit 5) as containing "highly toxic" PTW based on surface sediment concentrations for DDX, 2,3,7,8-TCDD, 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, and 1,2,3,4,6,7,8-HxCDF that exceed a 10<sup>-3</sup> excess cancer risk level for fish consumption based on the fish ingestion risks from the baseline human health risk assessment (BHHA). This definition of highly toxic based on a long-term (30 year) exposure to a chemical substance via a fish consumption pathway is not the intent of EPA's PTW fact sheet. These 10<sup>-3</sup> risk levels include long-term exposure parameters and indirect exposure based on a 30-year subsistence fish consumption scenario, which does not meet the definition of highly toxic (i.e., toxic under a direct contact or acute exposure scenario). Highly toxic levels should be based on direct*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*exposure conditions only. Furthermore, the 10-3 excess cancer risk is only a suggested basis and is not prescriptive.*

*The EPA's proposed highly toxic PTW levels should also be considered in a broader context. EPA's highly toxic PTW values for some constituents are well below cleanup levels and screening level for unrestricted use established for other sites and scenarios. For example, the PCB PTW value of 200 µg/kg is below cleanup goals for many other CERCLA sites, which are at or above 200 µg/kg, typically in the 1,000 µg/kg range. The EPA regional screening level (RSL) for residential soil in fact is 249 µg/kg; in other words, soil with PTW levels specified in the FS could be used as clean fill at homes, schools, and day care facilities. In this context it does not make sound technical or risk management sense for the PTW level to be set at 200 µg/kg. An approach more consistent with the intent of EPA's PTW guidance would be to set the PTW level at a 10-3 risk value based on direct contact to sediment (removal action objective 1 [RAO1]); that would be the lower of the 10-3 risk level (370,000 µg/kg), the hazard quotient (HQ) of 10 (147,600 µg/kg) (as stated in the guidance), or for the PCB case, the TSCA waste threshold (50,000 µg/kg). The use of the TSCA threshold for PCBs is also consistent with decisions at other CERCLA sites. A similar approach should be taken for the other constituents for which highly toxic PTW has been identified, especially dioxins/furans for which the PTW level in the FS is less than 3 times the EPA-recommended preliminary remediation goals PRG for dioxins/furans (once toxicity equivalence factors (TEFs) are applied). LSS believes that application of the revised and readily accepted PTW standards for not reliable contained or highly toxic material will result in none of the sediment at the Arkema site being identified as PTW.*

**EPA Position:**

LSS makes two main points on this issue: (1) "EPA should not identify. . . chemicals that require long-term exposure durations through indirect exposure pathways (i.e., consumption of fish tissue) . . . as "highly toxic" and (2) that there is no NAPL in the river adjacent to its facility.

On the first point, LSS provides no statutory or regulatory support for its position of what can or cannot be principal threat waste.

The NCP [40 CFR 300.430(a)(1)(iii)] states:

(iii) Expectations. EPA generally shall consider the following expectations in developing appropriate remedial alternatives:

(A) EPA expects to use treatment to address the principal threats posed by a site, wherever practicable. Principal threats for which treatment is most likely to be appropriate include liquids, areas contaminated with high concentrations of toxic compounds, and highly mobile materials...

The NCP does not say that principal threats at a site can't relate to contaminants posing a bioaccumulative risk. Identification of principal threats is a site-specific determination.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

EPA's *A Guide to Principal Threat and Low Level Threat Wastes* (1991) indicates that the NCP principal threat expectation reflects the belief that certain source materials should be treated given the long-term unreliability to contain them or the serious consequences of exposure if a release were to occur. Source material is defined as material that includes or contains hazardous substances, pollutants, or contaminants that act as a reservoir for migration of contamination to ground water, to **surface water**, to air, or acts as a source for direct exposure. (emphasis added) Identifying principal and low-level threat wastes combines concepts of both hazard and risk. In general, principal threat wastes are those source materials considered to be highly toxic or highly mobile which generally cannot be contained in a reliable manner and/or would present a significant risk to human health or the environment should exposure occur. Conversely, low-level threat wastes are those source materials that generally can be reliably contained and that would present only a low risk in the event of exposure. The manner in which principal threats are addressed generally will determine whether the statutory preference for treatment as a principal element is satisfied. EPA agrees that the NCP does not mandate a classification of wastes at a site.

However, EPA disagrees that the entire Portland Harbor site represents large areas with low concentrations of chemicals in sediments. The presence of liquid wastes such as NAPL, mobile source materials that are not readily contained, and contaminants that are highly toxic to sensitive populations are strong indicators of wastes that would be consistent with EPA's *A Guide to Principal Threat and Low Level Threat Wastes* as being identified as PTW. Likewise, the setting of the release of hazardous substances and the exposures that are likely to occur at a particular site is relevant to identifying principal threats. LSS's claims that the PCB PTW levels could be used as fill in a residential setting is totally irrelevant to this FS, which was analyzing cleanup alternatives for addressing contaminated sediment and surface water to protect the in-river receptors. Significant risks to wildlife and people, particularly, infants and children who eat or whose mothers eat resident fish from the site has been documented. Stating where the contaminated sediment could go or be placed and not be presenting a risk is irrelevant to the issue of what is principal threat waste in the lower Willamette River.

The identification of PTW at the Portland Harbor site is consistent with the NCP and EPA guidance. EPA's *A Guide to Principal Threat and Low Level Threat Wastes* further clarifies that principal threat wastes are "those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur." The guidance goes on to state that "no 'threshold level' of toxicity/risk has been established to equate to 'principal threat.' However, where toxicity and mobility of source material combine to pose a potential risk of  $10^{-3}$  or greater, generally treatment alternatives should be evaluated." EPA's guidance does not distinguish between risks due to indirect exposure associated with fish consumption and direct contact exposure. As a result, EPA's definition of highly toxic PTW is considered consistent with the NCP and EPA guidance.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

TSCA is not a factor for PTW identification. LSS indicates that the use of the TSCA threshold for PCBs is consistent with decisions at other CERCLA sites; however, the sites are not identified in the comment, and therefore, it is not clear whether the use of TSCA at the referenced “other CERCLA sites” was for identification of PTW or for other purposes such as a cleanup level or offsite disposal requirements.

EPA’s *A Guide to Principal Threat and Low Level Threat Wastes* states that “no ‘threshold level’ of toxicity/risk has been established to equate to ‘principal threat.’ The classification threshold value for PTW is based on site-specific circumstances. Consistent with the NCP and EPA’s PTW guidance and site-specific conditions, PTW has been identified based on a  $10^{-3}$  cancer risk (highly toxic) or NAPL within the sediment bed (source material) and on an evaluation of mobility of contaminants in the sediment.

LSS’s second point is whether NAPL exists at its facility. EPA disagrees with LSS’ assertion there is no evidence PTW as defined by EPA’s PTW fact sheet exists adjacent to its facility is without foundation, acceptance, or support. As noted in the comment, EPA has identified the presence of NAPL offshore of the Arkema site based on physical observations and other information indicating the presence of NAPL. Chlorobenzene is used in the DDT manufacturing process and the largest amount of chlorobenzene DNAPL is present under and around the manufacturing process residue (MPR) pond in the Acid Plant Area. This indicates that liquid chlorobenzene may have been discharged directly to the MPR pond along with other process residues. DDT is produced by combining chlorobenzene with trichloroacetaldehyde and an excess of chlorobenzene is essential to the reaction, which leads to considerable amounts of unreacted chlorobenzene being generated as a by-product with the DDT (Curtin, 1953). This means it is likely that large amounts of chlorobenzene were being discharged as liquid waste, a hypothesis that is supported by the information in the 2005 RI Report. The horizontal and vertical extent of chlorobenzene NAPL within the upland is also well documented in the 2005 RI report. Sediments and groundwater in the vicinity of Docks 1 and 2 have also been affected by the migration of the NAPL plume at the upland MPR pond and have high dissolved concentrations of chlorobenzene. Six sediment cores were indicative of the presence of NAPL based on field screening but none of these were conclusively identified as chlorobenzene NAPL. [AR Doc # 686965]

Qualitatively, soils with chlorobenzene concentrations greater than 10,000 mg/kg would indicate the presence of NAPL, however NAPL may also be present at lower concentrations (Feenstra et al. 1991). The highest chlorobenzene soil concentration identified in the Arkema RI is 43,000 mg/kg so the presence of chlorobenzene NAPL can be expected. Typically, dissolved concentrations greater than 1 percent of the aqueous solubility limit are suggestive of NAPL presence; however, concentrations less than 1 percent are not necessarily indicative of NAPL absence (Cohen et al. 1992; USEPA 1992a,b). The maximum in-water groundwater concentration and sediment porewater/transition zone water (TZW) concentration of chlorobenzene measured in the vicinity of Docks 1 and 2 is 64 mg/L and 30 mg/L, respectively. Both TZW and in-water groundwater concentrations are greater than 1 percent of chlorobenzene’s solubility of

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

500 mg/L (i.e., greater than 5 mg/L). The results do not show extensive visual evidence of chlorobenzene NAPL present in groundwater and sediment porewater; however, the dissolved chlorobenzene concentrations are deemed indicative of the presence of residual chlorobenzene NAPL in the vicinity of Docks 1 and 2 (CDM Smith 2013).

Core logs from sediment borings installed offshore of the Arkema site were evaluated to determine whether visual observations of blebs, globules, dark brown oily material, or other terms indicating presence of product were present. Other lines of evidence evaluated included sheens and odors along with corresponding elevated organic vapor meter (OVM) readings, transition zone water (TZW) and offshore groundwater concentrations at levels exceeding 1% of solubility, and the documented presence of dense non-aqueous phase liquid (DNAPL) in upland soils. These lines of evidence clearly indicate that NAPL may be present offshore of the Arkema site.

EPA acknowledges statements by ODEQ that multiple phases of sediment investigation have not encountered sediment exhibiting NAPL saturated conditions that would warrant thermal treatment prior to management and that the most significant observations have been the occasional sheen and product bleb. However, ODEQ also notes that it is possible that RD/RA activities could encounter a pocket of heavily NAPL impacted sediment and recommends that EPA adaptively manage these potential circumstances rather than ascribe a large treatment cost associated with these sediments to the Portland Harbor remedy. [AR Doc ID # 100019939] To estimate the potential treatment costs that may be associated with mobile PTW offshore of the Arkema facility in the 2016 FS, EPA applied no treatment to one-third of this material, solidification/stabilization to one-third of this material, and thermal treatment to one-third of this material. EPA has not made any decisions or requirements for treatment of this material at this time; this decision will be made in remedial design phase of the project.

Based on existing information, the 2016 FS assumes some pesticide/chlorobenzene PTW wastes will need to be dredged and disposed of off-site at the Area 7W SDU; however, it also assumes that not all contaminated sediment generated during dredging or capped in situ at the Area 7W SDU will require treatment. Remedial design sampling will need to further refine the waste characterization along with the identification of PTW at this area of the site; final dredge and capping footprints; and what treatment for off-site disposal may be required.

The EPA disagrees with the statement that it erred in identifying an extensive area of groundwater containing MCB DNAPL discharging to the river as “not reliable (sic) contained” (Exhibit 5). First, the figure referenced in Exhibit 5 does not show, nor intends to show a groundwater plume. The figure referred to in the comment, Figure 3.2-4 in the 2016 FS, presents an FS level understanding of the extent of contaminants within the river. This extent is based on limited remedial investigation sampling that bounds contaminant concentrations meeting PTW thresholds. The EPA anticipates additional, more extensive site data will be collected during the remedial design phase to refine this FS level characterization. Second, the assertion made in this comment that SCMs have

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

“cut off” and contained the groundwater pathway to the river from upland areas that have, or could potentially have MCB in groundwater, is not supported by any data, or information provided in the comment. Without this information, the comment assertions are speculative.

The EPA’s current understanding of the groundwater extraction and treatment system referenced in the comment is that there have been performance issues with the treatment system and biofouling of the extraction wells to the point that a Corrective Action Plan has been submitted at DEQ’s request (ERM West, Inc., 2016) providing a path forward to bring the system into compliance to meet its operational capture and treatment objectives so that DEQ and EPA can complete their evaluation of the operations effectiveness in cutting off and containing any potential ongoing source of dissolved phase contaminants discharging to the in-river sediment adjacent to the Arkema site. Further, the comment implies EPA’s alternatives evaluation is highly inaccurate without an accurate assessment of NAPL, PTW and PTW areas and quotes a sentence out of the 2016 FS Executive Summary to prove its point. EPA contends that appropriate FS level alternative assessment information is found within the body of the document and not exclusive to text within the Executive Summary. That said, it is unclear what specifically is inaccurate about the summary statement pulled from the executive summary. The 2016 FS presents an assessment of the extent of NAPL, PTW and PTW areas based on the RI data. Using this information and honoring the context of the Executive Summary statement, there is nothing inaccurate in the statement that “Alternative D has less capped area (71 acres), but does not reliably contain all PTW remaining in the river”.

**LSS Dispute Issue 3 - Inappropriate waste designation for sediments adjacent to the Arkema site**

*The assumed areas for disposal of sediment as RCRA waste (Figure 3.4-35, Exhibit 6) are based on a single toxicity characteristic leaching procedure (TCLP) sample for lead and no TCLP samples for chromium. Based on sediment analytical results, the area shown on Figure 3.4-35 does not represent sediment that will require RCRA Subtitle C landfill disposal. The State-listed pesticide residue designation also does not necessarily apply to sediment at the Arkema Site (Figure 3.4-36, Exhibit 6). As recently as February 2016 DEQ was researching the issue of whether sediment near Arkema would be designated a State-listed pesticide waste. Item 3 of the “Top 10 State Issues for Proposed Plan” document obtained from the LWG’s FOIA request (Exhibit 4) states that “Sean needs State determination of State-only pesticide question, which Matt is researching.” However, even if it is determined that some portion of the sediment is a State-listed pesticide residue waste, it would not preclude the placement of this sediment in a CDF (see HWIR discussion below) or disposal in a Subtitle D landfill out of state. When a State-listed hazardous waste is transported out of state (i.e., the Roosevelt Regional landfill presented in the FS), the Oregon State waste designation no longer applies, and the waste can be disposed as a non-hazardous waste so long as it meets other landfill disposal criteria. This waste disposal process was recently demonstrated by the disposal of soil from the Arkema Stormwater and Groundwater SCMs, which was disposed of at Roosevelt landfill in Washington.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*1 The analytical results minimally exceeded TCLP regulatory limits for lead in this sample. LSS notes that the TCLP samples were collected from specific intervals from single boreholes and were not necessarily representative of the general area around these boreholes. As perhaps a more appropriate approximation representative of bulk sediments, drummed sediments that contained the referenced sample intervals were re-sampled and analyzed for TCLP to evaluate the disposal options for these sediments, and none of those re-sampled drums exceeded the TCLP concentrations.*

**EPA Position:**

EPA made assumptions in the 2016 FS regarding waste disposal to develop a cost estimate. The State did not provide EPA with any definitive information on state listed waste designation, therefore, EPA did not assume that all waste removed offshore of the Arkema would be required to go to a Subtitle C landfill, only the portion that was identified as NAPL-NRC. As EPA clearly states in the 2016 FS, the ultimate disposal requirements will be set by the disposal facility after adequate characterization is accomplished and a disposal facility identified.

*Arkema disagrees with the cost assumption that “cement solidification/stabilization, low temperature thermal desorption, and no treatment will be used in equal proportions to treat pesticide/chlorobenzene PTW” for the disposal of dredged sediment that meets EPA’s PTW criteria from the Arkema site. Notwithstanding the fact that there are no PTW sediments currently identified off the Arkema Site, the FS fails to clearly outline the basis for EPA’s assumptions regarding treatment as a prerequisite for offsite disposal. Section 3.2.2.3 makes vague references to regulatory “standards” and “requirements;” however, it fails to clearly identify specific regulations and the conditions under which they are assumed to apply, or not apply, to sediments that are designated as PTW and the mechanism under which they derive need for treatment prior to offsite disposal. Furthermore, the “Top 10 State Issues for Proposed Plan” document obtained from the LWG’s FOIA request (Exhibit 4) states that “DEQ wants to be clear that land disposal of these sediments does not require treatment under Oregon Administrative Rules.” As presented, EPA has arbitrarily made more conservative assumptions for disposal of PTW defined by sediments containing DDx and NAPL than it has for PCBs, dioxin/furans, and PAHs. LSS believes that based on current data, none of the sediment at the Arkema site should be classified or handled as a Federal- or State-listed hazardous waste.*

**EPA Position:**

PTW has a statutory preference for treatment. EPA expects to use “treatment to address the principal threats posed by a site, whenever practicable” and “engineering controls, such as containment, for waste that poses a relatively low long-term threat.” [40 CFR Section 300.430(a)(1)(iii).] EPA identified potential PTW offshore of the Arkema Site (see Figure 3.2-4). Since it is currently unknown what, if any, treatment requirements will be necessary for disposal of removed waste offshore of the Arkema facility, EPA used a range of options to base the 2016 FS costs. The actual costs and requirements will not be

determined until remedial design or after removal and characterization of the waste and identification of the actual disposal facility.

**LSS Dispute Issue 4 - Inappropriate Application of the Hazardous Waste Identification Requirements (HWIR) Rule for Disposal of Sediment in a CDF**

*EPA's FS asserts that Dredged material subject to requirements of a permit that has been issued under Section 404 of the CWA is excluded from the definition of hazardous waste (40 CFR 261.4(g)). This provision is discussed in the Hazardous Waste Identification Rule (HWIR) (63 Federal Register [FR] 65874, 65921; November 30, 1998). Oregon State adopted the HWIR rule in 2003. This rule means that RCRA regulatory requirements do not apply to sediment dredged at the Site and disposed of on-site, such as at the Terminal 4 CDF, if the material otherwise meets the CDF acceptance criteria. (emphasis added)*

*EPA has correctly stated that RCRA regulatory requirements, including the designation of waste sediment as either a Federal or State-only hazardous waste, do not apply to sediment placed in a CDF; however, the statement mischaracterizes the CWA requirement that the sediment must meet CDF acceptance criteria for this rule to apply. This is simply not the case. Because DEQ has adopted the federal HWIR-media rule, and the CDF would meet CWA Section 404 requirements, RCRA Subtitle C requirements would not apply, and the dredged material placed in the CDF would not be a hazardous waste. The disposal of Arkema sediment in a Terminal 4 CDF should, therefore, be considered. The failure to consider CDF disposal for Arkema dredged sediment artificially inflates the disposal costs for alternatives related to the dredging at the Arkema site. In conclusion, EPA disregards the scope and intent of the HWIR Rule by placing arbitrary restrictions on what EPA believes can be placed into the T4 CDF if constructed. All of the EPA's Acceptance Criteria for the T4 are arbitrary and should be removed. Disposal of dredged material should follow the HWIR Rule as adopted by the State. This arbitrary action by EPA have severe negative implications for the FS and any subsequent RA.*

**EPA Position:**

EPA cited CDF acceptance criteria in the 2016 FS, Section 3.4.9.2. There are no statements in the 2016 FS that identify a CWA requirement that the sediment must meet CDF acceptance criteria. EPA developed the CDF acceptance criteria based on protectiveness.

**LSS Dispute Issue 5 - Feasibility study sediment and fish tissue dataset is not representative of current site conditions**

*EPA's draft final FS is based on a data collected between 1997 and 2007 and is not representative of current conditions at the site. The 2014 surface sediment PCB data collected by Kleinfelder to provide a current reference for comparison of the Portland Harbor RI dataset was not discussed or evaluated in the FS. It is unclear if the recent sediment PCB data collected by the RM11E Group was included in EPA's FS. These data are critical to the FS because the RM11E area is a source of PCBs in the upstream*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*portion of the site and has significant implications for assessing remedial alternatives, calculating SWACs, and assessing residual risk for the Portland Harbor site. PCBs are the primary risk driver for the Portland Harbor site and some of the most critical data for evaluating PCBs was omitted by EPA in the FS report.*

*A surface sediment and fish tissue dataset representing current conditions must be generated for the FS to accurately assess remedial alternatives. A new dataset will account for natural recovery that has occurred at the site since the Portland Harbor dataset was collected between 9 and 19 years ago and will fill a critical data gap in EPA's FS.*

*In Section 3.6.1.3, EPA's updated evaluation of fish tissue concentrations over time ignores 2002 data without any explanation. EPA states in this section a downward "trend" in fish tissue concentrations. In all but two instances (RMs 4E and 7E), concentration declines were not statistically distinguishable from zero. Possible explanations are the trend itself is close to zero, or the estimated coefficient could be very different from zero with a very wide confidence interval. The former would imply that the decay rate is small and that it is simply close to zero with strong level of confidence, whereas the latter indicates that the data are too sparse to precisely estimate the decay rate.*

*This section also states that the previous fish data are sufficient for baseline conditions for PCBs. This statement is incorrect since these data will be nearly 10 years old when the remedy is implemented and will not be representative of baseline conditions.*

*The Arkema pre-remedial design investigation work plan (Integral 2016) evaluated natural recovery at the Portland Harbor site (Exhibit 3, Appendix H). In this analysis, the original RI data sets were evaluated against more recently collected smallmouth bass fish tissue (2012), SPI (2013), and surface sediment PCB (2014) data. Based on a total of eight lines of evidence, including tests of statistical significance and a likelihood analysis, the weight of evidence strongly supports that natural recovery is occurring and will continue to occur within Portland Harbor. Therefore, MNR is a strongly viable process that should be utilized in Portland Harbor sediment remedies, including the area adjacent to the Arkema site. This analysis and its conclusions are directly relevant to EPA's alternatives analysis, comparison, and effectiveness evaluation, and therefore the lack of more recent data analysis biases the conclusions of EPA's alternative analysis and selection for sediment management areas (SMAs), including SMA 7W. EPA should incorporate the complete existing fish tissue data sets, as was done in the Integral (2016) analysis, and also allow for an updated fish tissue collection study to determine the current baseline fish tissue concentrations of COCs and demine the current site risk.*

**EPA Position:**

As described in Section 1.3 of the 2016 FS, the FS data set included data collected under EPA oversight through authority of the Portland Harbor, Gasco and Arkema AOCs. The data presented in the 2014 Kleinfelder report were not collected under an EPA-approved,

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

work plan. As noted in EPA's position to LWG's dispute issue 1d, Respondents' 2012 draft FS notes that temporal changes in contaminant concentrations were not an objective of the data collection efforts, and that the aggregated data collected between 1997 and 2010 has been deemed representative of current conditions in the site. As clearly stated in Section 1.3 of the 2016 FS, sediment data collected by the RM11E Group were not included in the 2016 FS because upon review, the data was not significantly different than RI data. Thus, it should not be "unclear" whether these data were included. The PCB SWAC concentration for SDU RM11E represents one of the highest concentrations within the Site, and LSS provided no information why RM 11E data would alter the FS analysis of alternatives.

The 2016 FS uses sediment data collected as recently as 2013, and presents and discusses contaminant concentration trends in fish using data collected as recently as 2012. Thus, the assertion the data are a minimum of 9 years old appears deliberately misleading. As noted in Respondents' FS, the large data set is considered adequate to represent current conditions and is adequate for evaluating alternatives in the 2016 FS. Additional sampling to more fully assess "current conditions" is a remedial design issue and beyond the scope of the 2016 FS and dispute.

Tissue data for smallmouth bass collected in 2002 are not directly comparable with the data collected in 2007 and again in 2011/12. Individual fish collected in 2002 were composited by river mile without regard to side of the river prior to analysis. In 2007, fish were composited by river mile but segregated by side of the river prior to analysis, while fish collected in 2011/12 were analyzed individually. As discussed in the ODFW 2005 study cited in the risk assessments, radio tracking of smallmouth bass indicated that their home range is typically between 0.1 and 1.2 km, and they exhibited a strong preference to remain in near-shore habitat. Given the heterogeneous nature of the contaminant distribution within the site, contaminant trends in fish were evaluated by river mile and by side of river. Because of the compositing scheme used in 2002, meaningful comparisons of these data with subsequent tissue results are not possible.

The term "baseline conditions" here defines the conditions prior to initiating a response action. As such, since the existing data represent conditions prior to initiating a remedial response, they represent "baseline" conditions. EPA does agree that additional tissue sampling prior to implementing a remedy is appropriate, as the current data set is limited to a single species (smallmouth bass) and a single contaminant (PCBs). The exact nature and design of such a sampling effort is beyond the scope of the 2016 FS and dispute. With regard to the age of the data at remedy implementation, given that the most recent tissue data was collected in 2012, EPA is disappointed to learn that LSS has no intention of performing any work prior to at least 2022.

The Arkema pre-remedial design investigation work plan was disapproved by EPA on March 30, 2016 for the reasons provided in the disapproval letter. EPA concurs that natural recovery is occurring within most areas of the Site and that it should be utilized in the sediment remedies, as evidenced by the fact that MNR represents the response action

assigned to between 64 and 90 percent of the total area of the Site for all alternatives carried through the detailed analysis in the June 2016 FS.

**LSS Dispute Issue 6 - Inappropriate use of PCB non-detected values in RAL and PTW footprint maps**

*The RAL and PTW footprint maps incorporate data with high PCB detection limits adjacent to the Arkema site (Exhibit 7). The high PCB non-detects with detection limits 5 times EPA's PTW value (e.g., >1 mg/kg) occurred in the Aroclor analysis as a result of a matrix interference with DDx. The RAL and PTW footprint maps should only consider detected PCBs based on PCB congener concentrations adjacent to the Arkema site due to the well-known matrix interference with DDx in PCB Aroclor analyses. The identification of PTW and remediation footprints for PCBs adjacent to the Arkema site based on non-detect values with elevated detection limits resulting from matrix interference with DDx is inconsistent with EPA's PTW fact sheet guidance and biases the assessment of PTW and remediation footprints for the SDU RM7W alternatives. This exaggerated PCB footprint will also bias the alternative selection for SDU RM7W. EPA should remove the PCB non-detect value from this PCB footprint analysis as it biases and exaggerates the area of PCBs in sediment at the site. If necessary, additional PCB congener data could be collected from these high non-detect sample locations to confirm the absence of high concentrations of PCBs at these locations.*

**EPA Position:**

EPA used the data provided by the LWG. The LWG did not indicate that there were any issues with this data nor did they remove this data from the database provided to EPA. If there were issues with this data, LWG should have flagged the data and resampled the Site using congener analysis. EPA agrees that congener, not Aroclor, data should be collected at this Site in remedial design. Review of the footprints for PCB RAL contours (Figure 3.4-7), DDx RAL contours (Figure 3.4-12), and dioxin/furan RAL contours (Figures 3.4-8, 3.4-9, and 3.4-10) indicates that the SMA footprint offshore of the Arkema property is largely driven by DDx and dioxins/furans and overlaps with the PCB RAL footprint; thus, omitting PCB data from this area would not substantially change the evaluation in the 2016 FS. New data will be collected in remedial design that will determine the SMA boundaries based on the final RALs selected in the ROD.

**LSS Dispute Issue 7 - Inaccurate RAL and PTW footprint maps**

*The PCB and PCDD/F RAL and PTW maps were contoured using natural neighbors gridding and did not account for the flow direction or depositional environments in a river system. The RAL and PTW maps in EPA's FS report blindly used nearest neighbor interpolation, and data points were inappropriately interpolated through upland areas. An example of this inappropriate interpolation is between points in the Willbridge Terminal and the area between Dock 1 and the Salt Dock on the Arkema Site (Figures 3.4-7, Exhibit 7 and 3.4-11, Exhibit 8). In this example, the points are not correlated and should not be interpolated through the upland portion of the Arkema site. The RAL and PTW maps must include some interpretation to reflect the physical features of the site and site uplands, as well as the hydrodynamics of a river system. This manual*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*interpretation should be done for the PCB and PCDD/F maps covering the area adjacent to the Arkema site.*

**EPA Position:**

EPA acknowledges the limitations of natural neighbor interpolations. However, the primary limitation to natural neighbor interpolations is data density. Because the Willamette River is subject to frequent flow reversals, considering flow direction is not expected to improve the accuracy of natural neighbor interpolations. With respect to consideration of depositional environments, EPA's natural neighbor interpolation divided the Willamette River into three lateral zones – west nearshore, navigation channel and east nearshore which is considered the key geomorphic factor affecting flow dynamics within the lower Willamette River. EPA also acknowledges that some of the interpolations extended through upland areas. However, these instances are few and not expected to fundamentally alter depiction of the distribution of contamination at the site.

**LSS Dispute Issue 8 - Inconsistent risk assessment methods and risk inequality for various compounds**

*Interim targets for risks and hazard indices (HIs), which were established by EPA in the FS "...to evaluate the potential for achievement of PRGs in a reasonable time frame" (Section 4.1.3) were not consistent between chemicals of concern (COCs) and RAOs. As such, estimated residual risks were not consistent among the COCs (e.g., total PCBs has  $5 \times 10^{-5}$  residual risk and DDx has  $1 \times 10^{-6}$  residual risk for RAO2 [Appendix J, Table J1-2]). This is mainly due to a very low and unattainable sediment PRG that was calculated using average fish tissue concentrations and ambient water quality criteria (AWQC) for surface water inputs to the food web model (FWM), which resulted in very low or even "0" value PRGs (issues related to the FWM are provided below in dispute issue 13). This then resulted in defaulting to background for several COCs. Remediation to background levels is not realistically achievable.*

*This FS also adopts entirely new methods to estimate pre- and post-construction risks for the alternatives (Appendix J). The residual risk evaluation process is neither technically sound nor transparent. There is no rationale or a clear example provided for the process. The FS states that methods used to evaluate residual risks are consistent with the Baseline Risk Assessments, but this is not an accurate characterization of these methods. Some examples of differences in risk assessment methods and assumptions include:*

- Fish meals/10 years was not used in the BHHRA and no rationale was provided in the FS for using this unit.*
- Appendix J presents the RM/SDU residual risks using fish ingestion rate of 49 g/day, however, PRGs based that ingestion rate have not been selected in the FS.*

*The difference in the risk assessment methods risks is apparent if the risks estimated for Alternative A (no action) are compared to baseline risks from the BHHRA—these should be the same.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*The only spatial scale that allows for direct comparison of risks is at the sitewide scale. The sitewide fish consumption risks estimated in the BHHRA (summarized in Section 1.2.5.1) are higher than those presented for Alternative A in Table J2.3-1a. However, the risks for Alternative A are based on average concentrations whereas the BHHRA risks are based on 95% upper confidence limit (UCL) or maximum concentrations. The average PCB concentration in the BHHRA based on actual tissue data was 160 µg/kg in bass and 2,500 µg/kg in carp, which includes a single outlier sample of 19,000 µg/kg (the average without the outlier is 353 µg/kg). The modeled tissue concentrations used for Alternative A are 352 µg/kg for bass and 820 µg/kg for carp, which are approximately 2 times higher than the measured tissue concentrations (excluding the single carp outlier).*

*The river mile risks for Alternative A cannot be compared directly with the BHHRA because the risks for Alternative A are on a rolling river mile basis for both sides of the river and navigation channel whereas the BHHRA risks were for an entire river mile. The risks for Alternative A are generally higher than those in the BHHRA (potentially due to spatial scale issues). In the BHHRA, risks at RM 11 were  $1 \times 10^{-3}$  and all other risks were less than  $1 \times 10^{-3}$ . For Alternative A, there are several segments with risks of  $1 \times 10^{-3}$  or higher.*

*There continues to be an issue with EPA's modeled dioxin/furan tissue concentrations. In the BHHRA, the sitewide risk from the total toxicity equivalent (TEQ) based on the 95% UCL or maximum concentration for actual tissue data was  $2 \times 10^{-4}$ . For Alternative A, the sitewide risk from 1,2,3,4,7,8-HxCDF alone based on an average concentration is  $6 \times 10^{-4}$  (Table J2.3-1a of EPA's FS report). There is no way that the risk from an individual congener can be higher than the total TEQ.*

*Furthermore, the residual risk assessment appears to present relative risks and not absolute risks. The term "residual risk" is used in different ways throughout the document, but it appears that EPA first estimated risks associated with the selected PRG (in general a risk of  $1 \times 10^{-6}$  or an HQ of 1 where the PRG is risk-based, but some other value if the PRG is not risk-based). For example, for RAO2, the residual risk (which is a ratio of the selected tissue PRG to the risk-based tissue PRG) for DDx is  $10^{-6}$  because the fish tissue PRG (3 parts per billion [ppb]) is equal to the risk-based tissue PRG (3 ppb). However, for PCBs, the risk-based fish tissue PRG is 0.5 ppb and yields a "0" sediment concentration, and the PCB sediment PRG, which is the background value of 9 ppb, is apparently used in the FWM to calculate a PCB fish tissue concentration of 23 ppb (Table J1-2 of the FS). The sitewide residual risk for PCBs was estimated to be  $5 \times 10^{-5}$  (i.e., 23 divided by 0.5 and multiplied by  $10^{-6}$ ). Then the "post-construction risks" was calculated for each alternative using SWACs to estimate fish tissue concentrations, again using the FWM and ratio of this "post-construction risk" and the "residual risk" to understand the "magnitude of residual risk." Again, this is relative risk and not absolute risk. Therefore, the risks between COCs are not comparable as some are based on actual risks (where the selected PRG is risk-based) and some are relative risks (where the*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*selected PRG is not risk-based). This approach is not at all consistent with the methods of the BHHRA and BERA and also misleading.*

*The post-construction sediment concentrations also appear unrealistic. For example, some of the PCB and DDX post-construction concentrations in Table J2.3 are below the background concentrations. Other tables in Appendix J show similar results. It is unclear how remedies will result in concentrations below background. In addition, the concentrations of COCs used in the remediated areas to calculate the post-remediation SWACs were 0, which does not account for dredge residuals or background (upstream) concentrations of COCs.*

*A significant deficiency of the residual risk evaluation is that it does not provide residual risks for any time frame other than the immediate post-construction condition (Time 0). As reported in the FS (Section 4.1.3):*

*As a long-term model is not available to predict the time to meet the PRGs, interim targets for risks and HIs were established to evaluate the potential for achievement of PRGs in a reasonable time frame, which was considered to be 30 years, commensurate with the site-specific contaminants and conditions. These interim targets are higher than residual risks once PRGs are achieved, and assume that further reductions will be achieved through MNR.*

*The calculated post-construction risks and HI values are higher than the interim target risks and HI. Because much of the remedy relies on MNR, the lack of a residual risk estimation process for time intervals post-construction (up to year 30) makes the usefulness of the residual risk estimates limited and almost worthless in terms of comparing the protectiveness of the remedies.*

*Furthermore, there is very little difference in net risk reduction between Alternatives B and I for almost all COCs. For most of the COCs, the differences are less than a factor of 2 and sometimes much smaller (e.g., difference in HQ of 0.25). Given the very conservative assumptions that were used to calculate PRGs, differences in estimated risks by a factor of 2 or less are not significant. A more reasonable criteria for evaluating differences in estimated risk between alternatives would be a factor of 10, which should be considered the minimum significant difference given the limited sensitivity of these criteria. A probabilistic-type risk evaluation, which incorporates the quantitative uncertainties, would be a more appropriate approach.*

*This small difference in risk reduction between alternative remedy scenarios is likely due to the driving PRGs being based on background. The risk associated with background levels of COCs should be presented in a side-by-side comparison to the residual risk estimates in order to demonstrate the benefit of the remedial measures to the public. Based on the residual risks presented, any remediation beyond Alternative B (which does show a great degree of risk reduction from Alternative A, no action, than the difference*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*between other alternatives) is unwarranted. The very large increase in costs for minimal and insignificant risk reduction between Alternatives B and I is not recognized in the FS.*

*In summary, the removal volumes in Alternative I cannot be justified as a cost-effective reduction of risk in comparison to other alternatives. Nor can the use of mixed criteria such as PRGs (and RALs) from different alternatives (i.e., “E” and “F” applied either site-wide or within an SMA) be justified based on differences in risk outcomes that are with an order-of-magnitude. To adequately assess the alternatives, an accurate assessment of risk needs to be completed using the risks identified in the EPA-approved BHHRA and BERA. The improper modifications to the risk assessments and assessments of residual risk should be removed from the FS document.*

**EPA Position:**

Residual risk is clearly defined in the 2016 FS as the cumulative risk associated with the PRGs, whether risk-based or otherwise. The use of a PRG associated with a background concentration, when that value is greater than a risk-based concentration, is consistent with EPA policy. LSS’ claim that “remediation to background levels is not realistically achievable” is simply declarative and wholly unsupported by any information provided by respondents. In fact, the 2014 Kleinfelder report repeatedly cited by LSS in this dispute presents a simple mean upstream PCB concentration of 5.8 µg/kg. This value is essentially the same as the UCL on the mean of 5.6 µg/kg PCBs from the background data set and presented in Table 7.3-1 of the final RI. Thus, if the more recent data submitted by respondents are taken solely at face value, the background levels presented in the 2016 FS are not only realistically achievable, but may be high relative to more recent data.

The number of acceptable fish meals per unit of time represents nothing more than a calculation of post-construction or residual risk, based on predicted tissue concentrations using the models developed and used by the LWG. Consistent with the assumptions used in the BHHRA, post-construction fish consumption risks on a river-mile scale were evaluated using PRGs calculated based on a consumption rate of 49 g/day.

Respondents’ assertion that “risks for Alternative A are based on “average concentrations” versus the “95% upper confidence limit” is directly contradicted by the information presented in the 2016 FS, which states in Section J2.1 “A site-wide average concentration for each COC – represented by the 95 percent upper confidence limit on the mean – was then calculated for each RAO 2 COC using ProUCL.” We note that according to EPA guidance, the 95 percent upper confidence limit (UCL) of the arithmetic mean should be used when calculating the “average” concentration to represent the exposure concentration. Further, EPA is unclear of the basis for respondents’ assertion that the average PCB concentration in the BHHRA was 160 µg/kg in bass and 2,500 µg/kg in carp, as Table 3-12 in LWG’s final BHHRA presents mean PCB (measured as Aroclors) tissue concentrations for whole body smallmouth bass and carp of 1,200 µg/kg and 1,700 µg/kg, respectively. The corresponding mean tissue

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

concentrations for PCBs measured as congeners are 1,100 µg/kg and 2,800 µg/kg in smallmouth bass and carp, respectively.

Risk estimates associated with consumption of fish presented in the 2016 FS were calculated using sediment data to estimate tissue concentrations, while risk estimates in the BHHRA used measured tissue concentrations. For the purpose of evaluating the effectiveness of different alternatives, sediment concentrations were averaged separately for each section by side of river to account for the fact that the majority of contamination, as well as habitat for fish is located in the nearshore areas. Respondents provide no basis in statute, EPA policy or guidance that an analysis of risks in the 2016 FS must aggregate data exactly as was done in the baseline risk assessments.

See EPA's position to LWG's dispute issue 1k regarding measured versus predicted dioxin/furan risks.

No definition of "actual risks" or "absolute risks" is provided. However, it appears LSS believes that risks associated with background concentrations qualify as "relative." Risk is directly related to concentration, and does not recognize the basis for that concentration. Thus, risk estimates for two or more different COCs are "comparable" and additive.

As noted, post-construction COC concentrations in areas assigned dredging or capping were assumed to be zero, as the 2016 FS assumed clean material would be used for caps, and that the residual layer applied to dredged areas would consist of clean sand. The absence of a defensible fate and transport model precluded estimating COC concentrations with any degree of certainty in these areas for any time-frame beyond the immediate post-construction period. Regardless, the same metric is used for each alternative, and the resulting comparative analysis is adequate for FS purposes.

The use of interim targets is consistent with EPA's sediment guidance. The degree to which estimated post-construction risks approach the risk associated with the proposed cleanup goals provides a measure of the degree to which MNR must be relied upon to achieve the cleanup. If, as LSS postures, the lack of an estimation process for time intervals post-construction renders the residual risk estimates almost worthless, the most logical conclusion would be for the ROD to acknowledge that limitation and select Alternative H, as it is the only alternative for which final COC concentrations can be estimated with any certainty.

No justification is provided by LSS for the assumption that a factor of 10 in risk estimates is needed to distinguish between alternatives. The effective use of probabilistic methods is reliant on the distribution of the estimates for the terms to be varied. The LWG's attempt at a probabilistic analysis (2012 Draft FS Appendix E) relied on assuming distributions for the population representing various inputs because the underlying data regarding the shape of the distribution was unknown. Further, EPA noted in its 2013 disapproval of the LWG 2012 draft FS that EPA guidance on probabilistic risk

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

assessment clearly notes that probabilistic methods should not be used to develop PRGs when point estimates were used in the risk assessment.

“Background risks” are explicitly included in the residual risk estimates presented in Appendix J1 for those COCs for which the PRG is based on background concentrations. Post construction risk estimates, and well as estimated costs, for Alternatives B and I are presented in the 2016 FS.

The 2016 FS does not conclude that the removal volumes in Alternative I are justified as “a cost-effective reduction of risk in comparison of other alternatives,” rather, the comparative analysis evaluates the relative performance of each alternative in relation to each specific evaluation criterion. The determination of the merits of Alternative I relative to other alternatives was made in the Proposed Plan, and Respondents dispute rights do not extend to that document. Respondents provide no support from CERCLA, EPA policy, or guidance to support their assertion that an order of magnitude difference in risk outcomes is needed to distinguish between alternatives. PRGs are not applied as a “mixed criteria” in the 2016 FS, the same PRG for each COC is used in all alternatives.

**LSS Dispute Issue 9 - RALs are not tied to PRGs and site risk**

*It is not clear how the RALs equate to risks, other than value for Alternative H, and only if based on the 10-6 risk-based PRG but not based on background. The risks from the RALs and background levels of COCs should be presented side-by-side to demonstrate the risk reduction for these alternatives.*

*Risk-based PRGs should be consistent with the spatial scales of the exposure scenarios used to characterize risk in the approved baseline human health and ecological risk assessments for evaluating cleanup alternatives. The spatial scales over which the PRGs are applied are a key element of the respective exposure scenarios being represented by the PRG. The spatial scales are as fundamental to establishing PRGs as the numeric values themselves. Various spatial scales were used in developing PRGs in the FS (Section 4.1.1): (1) Benthic risk was evaluated on a population level as the area exceeding RAO5 PRGs (2) 0.5 RM was used for RAO1 (sediment only) for direct contact exposure of people engaged in fishing activities, (3) 1 RM was used for RAOs 2 and 6 for the dietary exposure of humans and ecological receptors that consume fish and shellfish, and (4) Sitewide for RAO2. In the FS, COC concentrations were estimated on a rolling average developed from the surface sediment data in the FS database. Surface sediment results were averaged over a distance of 0.5 mile (RAO1) or 1 mile (RAOs 2 and 6) in successive 0.1-mile increments in both the east and west nearshore segments, and the navigation channel. Although the spatial scales match the baseline risk assessment exposure areas, the sediment concentrations calculated for the alternatives are not the same as in the baseline risk assessments and therefore, residual risks for the various*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*alternatives cannot be compared to baseline conditions, except for sitewide conditions (see dispute issue 8 above).*

*For RAO2, two scales were used to derive two sets of PRGs, sitewide and 1RM, using consumption rates of 142 g/day (based on the subsistence fisher) and 49 g/day (based on the recreational fisher), respectively. However, the selected PRGs for RAO2 are shown to be the ones derived based on the sitewide scale (shaded green in Table B3-5). The 1RM scale PRGs assume that recreational fishers will only be exposed to that portion of the river, which is a very conservative and unrealistic assumption. The RALs for RAO6 only used the 1 RM scale. This corresponds with the home range of species such as smallmouth bass, hooded merganser, osprey, bald eagle, and mink that were evaluated in the BERA. Ecological risk is managed on a population scale and even if a home range is within a river mile, the contiguous population may be exposed over a larger area.*

*In summary, the spatial scales, exposure scenarios, and estimation of exposure concentrations for the remedy development and residual risk evaluations vary from those used in the BHHRA and no clear rationale is provided for the approach.*

**EPA Position:**

It seems that the Respondent is confused between PRGs and RALs. PRGs are established in various media using risk-based values, ARARs, and consideration of background. PRGs are developed independent of spatial scales in Section 2 of the 2016 FS. However, PRGs are evaluated at relevant spatial scales based on exposure assumptions developed in the baseline risk assessments in Section 4 of the 2016 FS. Respondent agreed that the spatial scales used in the 2016 FS matched the baseline risk assessment exposure areas. The disparity in the risk estimates calculated in the baseline risk assessments for exposure to sediment and those in the residual risk estimate is due to the aggregation of the data. The baseline risk assessments aggregated data by dividing the site into discrete areas based on exposure (for RAO 1 direct contact to sediment, the river was divided into nearshore areas and then further divided into 0.5 river mile segments – RM 0-0.5, RM 0.5-1, RM 1-1.5, etc.) whereas the 2016 FS evaluated the same 0.5 river mile exposure assuming that the exposure could be to any 0.5 river mile (for RAO 1, the river was divided into nearshore areas and then divided into 0.5 river segments by 0.1 river mile increments – RM 0-0.5, RM 0.1-0.6, RM 0.2-0.7, etc.). Further, most of the risks in the baseline risk assessments were based on measured tissue data whereas the 2016 FS used models to predict tissue concentrations based on sediment concentrations. Again, the fish tissue data were aggregated by segmenting the river while the 2016 FS did not assume that fish reside only in a particular river segment, but could reside in any part of the river within that spatial scale. The BHHRA evaluated fish consumption on a Site-wide scale using 142 g/day consumption rate and a one river mile scale using 49 g/day. The 2016 FS used this same assumption and spatial scale; thus, is consistent with the BHHRA. Since EPA used this approach consistently to the no action alternative and to each of the

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

remedial alternatives evaluated, the comparison of alternatives in the 2016 FS can be compared to the baseline conditions at any spatial scale considered.

*In Table 2.2-3, several COCs have “A” under the columns for RAOs 3, 4, or 8. It is unclear why this is necessary. There are no data to justify selection of ARAR-based COCs as provided in Table 2.2-3a. The FS text simply states “contaminants that were detected in upland media (storm water and groundwater) that may potentially migrate to the river at concentrations that would exceed the Safe Drinking Water Act MCLs and national or State of Oregon water quality criteria were also designated as ARAR-based COCs.” Data or references are required to substantiate this assertion. In addition, the rationale behind assignment of ARAR-based PRGs is not clear and transparent.*

**EPA Position:**

All of the “A” designations under RAO 3 are incorrect and should be “R.” See EPA position to LWG’s dispute issue 1d regarding application of MCLs and ARARs.

*For some COCs (PCBs and dioxin/furan congeners), the sediment PRGs (RAO2) that were developed using the FWM based on target tissue concentrations were assigned a value of zero. Therefore, the PRGs selected for these COCs are background. The mathematical rationale provided is that when using the FWM, dissolved concentrations alone are predicted to result in estimated tissue concentrations greater than the risk-based target. This indicates some flaw in the FWM. Appendix B also states that the FWM presented in detail in the Bioaccumulation Modeling Report (Windward 2015) was submitted to, but not approved, by EPA. However the sediment PRGs for RAO2 and RAO6 are based on this FWM. Note, for RAO6, sediment risk-based sediment PRGs could be estimated for PCBs and dioxins/furans (much higher than background). For the FWM, the OR AWQC were used as post-remedial water concentrations. Note that LWG has disagreed with the use of AWQC in the FWM; instead upstream water concentrations should be used.*

**EPA Position:**

EPA disagrees that surface water concentrations alone can result in tissue concentrations that could pose unacceptable risk. Such a statement indicates a fundamental lack of understanding of the Arnot and Gobas model used by the LWG. The Arnot and Gobas model is a complex, fugacity-based model that estimates tissue concentrations resulting from exposure through a variety of measures, including gill uptake and dietary exposure, as well as accounting of transformation and elimination through metabolic processes. The mechanistic nature of the model is such that certain model outputs in fact represent inputs to other portions of the model. For example, the dietary preference for certain fish may consist of a sufficient proportion of zooplankton and phytoplankton such that exposure via diet alone, or in combination with gill uptake may result in a tissue concentration exceeding risk-based concentrations, particularly in species that prey on planktonivorous fish. In fact, the LWG’s submittal of Early Preliminary Remediation Goals (March 2009) presented sediment PRGs for several contaminants as “<0,” indicating that a sediment concentration of 0 in conjunction with the input water concentration resulted in an

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

estimated tissue concentration exceeding the risk-based target. The LWG did not identify this as “some flaw in the model” when it submitted the report to EPA for approval.

While the Bioaccumulation Modeling Report as submitted by LWG was never approved, EPA did notify the LWG on November 18, 2014, that the Arnot and Gobas food web model as calibrated by the LWG was approved. [AR Doc # 100005458] Since AWQC represent ARARs in surface water that must be achieved, EPA believes they appropriately represent surface water concentrations to calculate PRGs in sediment using the food web model.

*It is also not clear if risk from background was accounted in the risk reduction. In addition, some of the post-construction calculated sediment concentrations are below background.*

**EPA Position:**

Risk from background was accounted for in the residual risk if background exceeded the risk-based PRG. Post construction calculated sediment SWACs were calculated using a replacement value of zero (the assumption was that clean material would be used in caps and residual covers). If enough of the values in a SWAC area are replaced with zero, it could result in a concentration below background. This would mean that the alternative is more aggressive than necessary to achieve the PRGs. EPA acknowledges that after the remedy is constructed, surrounding sediment and upriver sediment will mix with the clean material which will result in some equilibrium concentration greater than the post construction SWAC, but could not be calculated due to too many unknown variables (area-specific deposition rates, depth of mixing, sediment transport rates in the Site, etc.) and is too difficult to compute without a functioning fate and transport model.

*The RALs developed for dioxins and furans in the FS (Section 3.4.1.2) are based on several assumptions leading to low confidence and high degree of uncertainty. PRGs for dioxins/furans are less than or within the MDLs. The FS recognizes that due to low data density, interpolations are required across large areas with no data, leading to large footprints that exceed these uncertain RALs.*

*The RALs need to be related to the PRGs for the site that were developed from the EPA-approved BHHRA and BERA. The spatial scales, exposure scenarios, and estimation of exposure concentrations for the remedial levels, should be on the same basis as for the BHHRA and BERA. Remedial levels should be no lower than background for COCs that have PRGs that based on background. Uncertainty in remedial areas identified needs to be accounted for in the cleanup area assessment especially for COCs that have small data sets and low data density, such as dioxins and furans.*

**EPA Position:**

PRGs developed for dioxins/furans are all quantifiable. All RALs developed for focused COCs, including dioxins/furans, are all greater than the PRGs. EPA agrees that there is a higher degree of uncertainty in the dioxin/furan areas delineated in the 2016 FS, but that

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

the estimated costs are within the accepted cost range of +50/-30 percent. It is expected that that uncertainty will be resolved in remedial design.

**LSS Dispute Issue 10 - PRGs and RALs are inconsistent with other sediment sites**

*EPA's Portland Harbor PTW value for total PCBs (200 µg/kg) is much lower than the hot spot remediation and expanded hot spot remediation values for the Hudson River site (30,000 and 10,000 µg/kg, respectively). Cleanup goals for other sites are significantly higher than the PTW concentration for Portland Harbor and were not defined as PTW for these other sites. For example, the PCB cleanup goal protective of human health is 386 µg/kg for Yosemite Slough in San Francisco, California; 1,240 µg/kg for Hunters Point, California; and 1,000 µg/kg for Fox River, Wisconsin. The cleanup goal for Passaic River in New Jersey is based on the background of 460 µg/kg. All of these cleanup goals protective of human health are greater than the 200 µg/kg PTW value for PCBs proposed for Portland Harbor.*

*PRGs developed in the FS using parameters and assumptions used in the baseline risk assessment are considered very conservative. For the BHHRA, upper end of the exposure parameters were used for estimating risks. For example, assuming a subsistence fisher would consume fish 149 g/day from the site alone is highly unlikely. Not refining these conservative assumptions for developing PRGs is considered unrealistic. The FS should utilize assumptions and targets that are reasonably achievable given the background conditions and other factors affecting implementability.*

*EPA's use of sediment PRGs for riverbanks, even on areas rarely inundated and without considering attenuation, is technical inappropriate. Delineations of groundwater plumes and riverbanks, and a zero post-construction restoration time frame are arbitrary. There is a total lack of data and analysis as to what risk considerations are driving the specific remedial actions delineated (and therefore how this will be refined in the design phase when further data/analysis is available) and what specific remedial actions will be implemented in which areas driven by those risks. This arbitrary delineation is then carried forward into the evaluation of alternatives and given weight for assessing the relative effectiveness of alternatives.*

*EPA's Portland Harbor PTW value for total PCBs (200 µg/kg) is much lower than hotspot remediation and cleanup goals for other PCB-impacted sites. EPA should modify the PTW values in the FS to make them consistent with other sediment sites such as the Hudson River site noted above.*

**EPA Position:**

As a general matter, the NCP provides a framework for assessing and managing risks at Superfund sites. More information and many recommendations for assessing both human health and ecological risks and developing cleanup levels are provided in several guidances and fact sheets issued by the Superfund program. These guidances by design are not prescriptive and provide the regions with discretion to make decisions based on site-specific data and information. A principal tenant of the Superfund program is that all

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

baseline risk assessments and cleanup levels should be based on site-specific exposure data and the reasonable maximum exposure that could occur at a site. Cleanup levels typically are based on site-specific risk, ARARs or background.

Based on site-specific information, EPA applies the reasonable exposure pathways, exposure factors, and risk level within the  $10^{-4}$  to  $10^{-6}$  risk range (with  $10^{-6}$  being the point of departure) for choosing cleanup levels appropriate for the site. Different site-specific circumstances can account for the variability in cleanup goals between sites. Sediment cleanup goals and fish tissue targets may not be set at risk-based concentrations, where site-specific conditions, background concentrations, and available remedial technologies indicate that risk-based goals are not expected to be achievable. Under these circumstances higher cleanup levels may be set, in addition to fish consumption advisories to reduce exposure and to achieve protection.

The Portland Harbor risk-based goals for individual contaminants are based on  $10^{-6}$  cancer risk or a non-cancer hazard of one and achieve a cumulative cancer risk level at  $10^{-5}$  to comply with Oregon's residual risk ARAR for this Site. That level of protection for most exposures is achievable at Portland Harbor based on current information. Where sediment background concentrations are higher than that risk level, background concentrations are used.

Risk-based PRGs in the 2016 FS are developed consistent with the exposure assumptions in the baseline risk assessments. Consistent with the BHHRA, both the subsistence fisher consumption rate of 142 g/day and the recreational fisher consumption rate of 49 g/day were used to develop risk-based PRGs in the 2016 FS (see Appendix B). The Respondent does not provide any detail as to which 2016 FS assumptions and targets are not readily achievable given background conditions nor provides which factors affecting implementability are not reasonable. EPA believes that the 2016 FS assumptions and targets are reasonably achievable, considered background conditions, and factors affecting implementability.

LSS complained that our PTW values and our PRGs for PCBs were lower than cleanup levels at other sites. As stated above, every cleanup decision is based on site-specific circumstances. Likewise, the cleanup decision itself can be structured in many different ways making simple comparisons of "cleanup" numbers misleading at best and just plain wrong at worst. A cursory review of the site decision documents for the sites and "numbers" referenced by LSS illustrates this point. The Hudson River numbers LSS references were hot spot remediation levels that required removal, not the final cleanup goals. The Yosemite Slough is a removal action and may only be addressing ecological risks. The Hunters Point site from what we could tell has not made a final cleanup decision at this time. Furthermore, 1ppm is only the remedial action level at the Fox

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

River site, not the final cleanup goals which are not significantly higher than PRGs proposed for Portland Harbor.

**LSS Dispute Issue 11 - Methodology for calculating background concentrations**

*EPA's proposed background values based on inappropriately derived upstream bedded sediment statistics are unlikely to represent achievable cleanup levels for the site. The FS also does not present background concentrations for surface water and does not present sediment background concentrations for all chemicals with sediment PRGs.*

*A sediment remedy must include evaluating what is deposited within the Study Area, both physically and chemically (i.e., potential future bedded sediment equilibrium). EPA has not conducted such an evaluation. The cleanup goal for PCBs of 9 ppb based on EPA's calculation of background concentrations is not achievable. Background should not be used to establish cleanup goals when likely ongoing contaminant inputs from upland sources within the Site and upriver of the Site exceed EPA's calculation of background. The LWG provided EPA an evaluation of equilibrium concentrations for the Site that are a much more reliable indicator of future concentrations that can be achieved.*

*More specific detail is provided below for PCDD/F compounds in sediments and other COCs and media.*

**EPA Position:**

Background values were derived using data specific to the Portland Harbor site and overall watershed. Use of site-specific information is consistent with EPA background guidance, and because site-specific data are available, comparisons to other urban watersheds, which may or may not be similar to Portland Harbor, are not relevant.

See EPA's position to LWGs dispute issue 1g.

**LSS Dispute Issue 11a - Background concentrations PCDD/F compounds in sediment**

*Sediment PRGs for RAO2 and RAO6 as well as riverbank PRGs for RAO9 for the five PCDD/Fs congeners are based on background concentrations. Background PCDD/F concentrations for individual congeners are presented in Appendix B, Table B2-4 of EPA's FS.*

*EPA uses new methods for deriving these levels that appear significantly different from both EPA's methods for other chemicals as well as past LWG input on this subject. Sediment PRGs for RAO2 and RAO6 as well as riverbank PRGs for RAO9 for the five PCDD/Fs congeners are based on background concentrations.*

*The background values are based on limited and poor quality data (with elevated detection limits). In fact, only one congener has sufficient data (1,2,3,4,7,8-HxCDF) to calculate a background value and even that is limited (13 of 31 samples were non-detects). Thus, most of the background "values" are based on a 95% UCL of the*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*detection limits. The background values also appear skewed quite low compared to other urban watersheds.*

*The background values estimated based on this limited data and approach, furthermore, are low and approximately an order of magnitude lower than values from other regions and watersheds. For example, a memorandum published by EPA in 2010 provides a good summary of background levels for dioxins/furans in sediment, which range from approximately 2–5 parts per trillion (ppt) as TEQs. It also summarizes values from Puget Sound which include a TEQ value of 4 ppt for non-urban areas but allowing up to 10 ppt as TEQs for open water disposal; this value is also used in San Francisco Bay and elsewhere.*

*(<https://klamathrestoration.gov/sites/klamathrestoration.gov/files/EPA%20Klamath%20dioxin%20memo%201-13-10%20final.pdf>). The Duwamish Waterway FS establishes an upper bound background value for dioxins/furans as 11.6 ppt TEQ.*

*Background values in other regions and watersheds are expressed as TEQs, which is generally the manner in which cleanup goals for dioxins/furans are expressed. For Portland Harbor, EPA used 5 individual congeners. The individual congener background values provided in Appendix B of the FS and in the PRG tables for RAOs 2 and 6 can be converted to TEQs using TEFs, which results in a value of 0.56 ppt on a TEQ basis (since the 5 congeners equate to the majority of the risk, this value may be slightly biased low, but probably less than 10% of the total TEQ). This background value is an order of magnitude or more lower than the range of values, mainly for non-urban areas, from the literature. A study to better define background levels for dioxins/furans is necessary since the calculated risk-based PRGs are well below even these low-biased background levels resulting in the background values being adopted as the final PRGs. Otherwise, it is unlikely that the remedies for dioxins/furans will be successfully implemented and estimated risk reductions for dioxins/furans will be realized. This latter issue addresses the validity of the alternatives analysis and its biased outcome.*

*It should also be noted that no background values are listed for RAOs 1 or 3. Those PRGs are expressed as TEQs and data is lacking to identify a background level on a TEQ basis. This needs to be rectified; those PRGs may be below background. In fact, the PRG for RAO3 is 4 orders of magnitude below the MCL and is likely not measurable at that level. Overall, providing PRGs that are below MCLs is inconsistent with other cleanup actions under CERCLA or other programs. Cleanup to below MCLs is unlikely to be achievable.*

**EPA Position:**

As noted in Section B2.4, background for 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, 2,3,7,8-TCDD, 2,3,7,8-TCDF were established as the 95th percentile of the detection limits in the background data due to the very low frequency of detection of these analytes in the background data set. Thus, any detection of these congeners can be construed as representative of contamination. Respondents' calculation of a background value on a TEQ basis appears contradicted by their subsequent statement that "data is lacking to

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

identify a background on a TEQ basis.” EPA continues to believe that background values in sediment expressed solely as a TEQ would be inconsistent with the risk assessments, which assess exposure via bioaccumulation through the food chain. Information submitted to EPA by the LWG in its validation of the food web model for dioxin/furans clearly demonstrates that the individual congeners bioaccumulate at different rates, and information presented in the 2016 FS Section B2.2 demonstrates that calculated TEQ values in sediment do not correlate with calculated TEQ values in biota. The PRG for dioxin/furans is based on Oregon water quality standards.

**LSS Dispute Issue 11b - Background concentrations for other COCs and media**

*The FS (Section 2.2.2.4) states that only sediment background concentrations were estimated and background concentrations for other media could not be calculated due to insufficient data. However surface water background concentrations were calculated in the RI. Upriver surface water background concentrations COCs are orders of magnitude higher than the ARARs based on the AWQC. Note, the background UCLs for upriver surface water (dissolved concentrations with outliers removed; Table 7-4b of RI) vs RAO3 AWQC-based PRGs. For example, the background UCL concentrations for DDT, PCBs and TCDD Teq are all significantly less than the respective RAOs for these substances:*

- *background UCL for DDT = 0.000114 µg/L and the ARAR (RAO3) is 0.00002 µg/L*
- *background UCL for PCBs = 0.000126 µg/L and the ARAR (RAO3) is 0.000006 µg/L*
- *background UCL for TCDD Teq = 0.000126 µg/L and the ARAR (RAO3) is 0.000000033 µg/L*

*Because of the deficiencies in determining the background levels, a new background study for sediment, surface water and tissue needs to be conducted in the design phase. The results of this evaluation need to be used to update PRGs, RALs and SDUs.*

*EPA should not use background to establish cleanup goals when likely ongoing contaminant inputs from upland sources within the Site and upriver of the Site exceed EPA’s calculation of background. A better approach was provided by the LWG using equilibrium values.*

**EPA Position:**

See EPA’s position to LWG’s dispute issue 1g.

Respondents refer to Table 7-4b of the RI; however, the Final RI does not contain a Table 7-4b.

**LSS Dispute Issue 12 - Benthic risk models do not honor the measured data**

*EPA made extensive changes to the benthic approach for this FS, but those changes are still inconsistent with the comprehensive benthic risk approach contained in the approved BERA). The FS states: “The protection of benthic species to contaminated sediment is evaluated using the benthic risk area defined by an order of magnitude greater than the RAO5 PRGs. The post-construction interim target for RAO5 was established at 50%*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*reduction in the area posing unacceptable benthic risk.” So, instead of using the CBRA, EPA now maps benthic PRG exceedance factors on a point-by-point basis and uses a 10 times exceedance factor to identify areas of concern. EPA then concludes that if 50% of this area is actively remediated, the alternative is “protective” on an interim basis. It is completely unclear how this new method is: 1) in any way more accurate or consistent with the BERA; and 2) more predictive of benthic risk or the effectiveness of the alternatives, as compared to simply using the CBRAs, which are entirely consistent with the BERA.*

*Furthermore, and most importantly, the benthic risk models used by EPA do not honor the measured data. Although the LRM and FPM are model predictions using data from the toxicity tests conducted with site sediments, much of the measured data is not honored. Any modeled risk for benthic invertebrates that ignores actually toxicity testing results needs to be assessed in weight-of-evidence and river-mile specific decision-making. The benthic risk footprints should not extend into areas shown to have a lack of toxicity based on actual laboratory toxicity tests. This error has been carried through the alternatives analysis and therefore has biased the selection of alternatives for SMAs in the FS.*

*EPA should modify the benthic approach in the FS so it is consistent with the BERA and honors all measured data.*

**EPA Position:**

See EPA Position to LWG dispute issue 1b.

The benthic risk models were not used by EPA in the 2016 FS. The benthic risk models were used by LWG contractors (Windward Environmental) to determine risks in the BERA. EPA used the outputs of those models provided as a GIS layer in developing the maps in the 2016 FS, Appendix D10. However, the comprehensive benthic risk map (2016 FS Figure 4.1-1) was developed using interpolation of surface sediment concentrations exceeding the RAO 5 PRGs. Since EPA is not requiring action based on these PRGs, they will be monitored post construction until such time as they are achieved.

**LSS Dispute Issue 13 - Food Web Model (FWM) for DDx and PCDD/Fs**

*The FWM is used by EPA to back-calculate concentrations of chemicals of concern (COCs) in sediment associated with acceptable, risk-based human health and ecological concentrations in fish tissue as calculated using the baseline risk assessment (Kennedy/Jenks, 2013). This influences sediment PRGs and hence RAOs, so uncertainty originating with the FWM cascades, having compounding effects on the evaluation of remedy alternatives, and could result in additional remediation costs with no meaningful*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*gains in risk reduction. We identify the following shortcomings with EPA's application of the FWM at the Site:*

*A comprehensive and detailed Conceptual Site Model (CSM) for the Site in total, and for the relationship between COC sediment and fish tissue concentrations specifically, has not been presented by EPA. This means that EPA's chief assumptions for the FWM related to steady-state conditions (in a major river), the completeness of the site characterization dataset, regional contributions of COCs, and the apparent relationship between sediment and fish concentrations.*

*Based on an examination of the empirical data for the Site, no statistically significant relationship is observed between sediment and fish tissue concentrations for DDx and PCDD/Fs at the concentrations relevant to risk decision making. This means that the FWM - which assumes such a relationship exists - is not reliable and that the conclusions reached on its basis are fundamentally inaccurate.*

*Good modelling practice was not used by EPA for the FWM, and in particular sufficient model documentation detailing the work does not exist. Adequate model documentation is one of several criteria used by EPA and other international regulators for determining the acceptability of a model for regulatory decision making (USEPA 2009, EFSA, 2014, Grimm et al., 2014).*

*EPA should not use their FWM to evaluate sediment PRGs if there is no statistical relationship between sediment and fish tissue concentrations for key COCs such as DDx and PCDD/Fs.*

**EPA Position:**

See EPA's position to LWG's dispute issue 11.

**LSS Dispute Issue 14 - Overly prescriptive and flawed approach used to assign remedial technologies**

*The FS acknowledges uncertainties in site characterization and the conservative assumptions used to form the basis for associated technology assignments, however EPA continues to use a prescriptive set of technology evaluation and scoring criteria to determine the technologies to be applied in each area of the site and, with the exception of a vague paragraph in Section 3.8.1, the FS is silent regarding the degree of flexibility that is envisioned to be available during remedial design to refine technology assignments based on the additional information gained through future pre-design investigations. This will lead to a lack of flexibility with regard to technology assignments, depth of removal, potential improvements in technology, design efficiencies to address remedial and CWA/ESA requirements, etc.*

*EPA should clearly explain the conditions under which changes to major alternative elements (e.g., changes in technologies assignments, methods to address PTW, methods for determining treatment and disposal requirements, requirements for rigid*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*containment) might be considered or allowed. EPA should explain how new data, including the “initial conditions” assessment will affect the selection of alternatives and the RAL boundaries based on current surface sediment concentrations. The FS should include language to allow for updates to risk assessments. EPA should incorporate decision frameworks for proposing equally or more effective capping options or other technology refinements based on detailed design-level evaluations and new data.*

*Specific examples of EPA’s flawed approach for assignment of remedial technologies:*

- EPA makes unsupported assumptions regarding nature and extent of contaminated groundwater discharge which drive inappropriate, prescriptive technology assignment decisions that fail to provide flexibility to develop appropriate site-specific designs and mandate use of potentially unnecessary materials (e.g. reactive amendments and/or cap armor).*
- The FS fails to provide evidence supporting speculative assertions of groundwater impacts, and selectively ignores facts including the physical effects of upland controls on contaminant transport/mobility (i.e., significant reduction in advection) which would otherwise allow for remedial design that considers, and is compatible with, upland SCMs. Similar to EPA’s treatment of riverbank areas (Item 18 below) arbitrary assumptions regarding nature/extent of contaminated groundwater are carried forward into the evaluation of alternatives and given weight for assessing the relative effectiveness of alternatives with respect to RAOs 4 and 8, which biases the outcome of alternative selection.*
- While EPA’s decision trees prescribe specific technologies amenable for use under heavy structures, it fails to consider the need for flexibility during design to adapt to any number of other site-specific constraints including slope stability, proximity to nearshore structures, etc. and preclude use of other technologies of potentially equivalent effectiveness.*

*EPA should modify the FS to clearly explain the conditions under which changes to major alternative elements might be considered, explain how new data will affect the selection of alternatives and the RAL boundaries based on current surface sediment concentrations, include language to allow for updates to risk assessments, and incorporate decision frameworks for proposing equally or more effective capping options based on detailed design-level evaluations and new data.*

**EPA Position:**

The Respondent is confusing the requirements for an FS with the requirements for a ROD. The sole purpose of the FS is to develop remedial alternatives to be compared to each other in order to select a preferred alternative. The technology assignments in the 2016 FS are based on current information about the Site. The 2016 FS makes specific assumptions based on current conditions to develop remedial alternatives that can be compared to each other to inform remedy selection. Costs cannot be derived in the FS unless a technology is selected and evaluated. EPA used several lines of evidence based on site conditions described in the RI report to determine the appropriate technology to apply to various areas of the Site. The information and flexibility Respondents seek to be

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

discussed in the 2016 FS do not inform the evaluation of the NCP criteria and are more appropriately discussed in the ROD. Thus, EPA does not consider this a dispute issue for the 2016 FS.

**LSS Dispute Issue 15 - Prescriptive dredge residuals management strategy**

*The prescribed application of 12-inches of sand across the entire dredge footprint (amended with AquaGate+PAC2 in areas where PTW present) is very poorly supported. The FS is misleading in stating that the placement of sand (and GAC in areas where EPA has speculated that PTW is present) immediately following dredging will eliminate the need for additional dredge passes. The FS indicates that sediment cores would be taken post-placement to verify thin-layer residual cover successfully reduces residuals concentrations. It is inappropriate to assume a 12-inch layer of residuals management cover will be applied across the entire dredge footprint, without providing a strategy that will determine the necessity for thin-layer placement and flexibility to develop an appropriate thickness.*

*As PAC can be toxic to benthic organisms, overall quantities, where and how it is applied warrants more thoughtful consideration. The FS neglects to consider the physical stability of PAC in the deployment of the thin-layer residuals cover. PAC will be ineffective if it immediately washes away. The FS neglects to consider any possible unintended consequences that may be posed by transport/erosion and aggregation of PAC (with, or without adsorbed contamination) in depositional areas. The assumed performance requirements for this residuals strategy are unclear.*

*The prescriptive dredge residual strategy should be removed from the FS. If left in, the strategy and rationale for the residual management approach should be clearly explained, and a flexible, objective approach to assessing the need for and approach residual management should be allowed.*

*2 The text makes numerous inappropriate references to specific commercial products (i.e., AquaGate+PAC, Aquablok) as components of the conceptual remedial design. The FS should provide flexibility to consider other commercially products for a given class of technologies.*

**EPA Position:**

EPA made an assumption in the 2016 FS regarding the type and quantity of material to be used in dredge residual management in order to develop costs. The actual type and quantity of material needed for dredge residual management will be area-specific and determined in remedial design. However, EPA acknowledges that the use of a residual management layer can reduce costs of both post dredge sampling and multiple dredge passes to achieve remediation goals.

**LSS Dispute Issue 16 - Inappropriate use of rigid containment technologies**

*EPA assumes the use of sheet pile barrier walls as dredge water quality control measures based on the suspected presence of NAPL will support the short term effectiveness of all*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*alternatives. The FS still fails to adequately evaluate the implementability, effectiveness and cost of this particular technology relative to other technologies and BMPs.*

*In making gross assumptions for this FS, EPA has disregarded the complexity of constructing such barrier walls (e.g. consideration of structural components such as king piles and structural bracing, or more complex cofferdam structures) and the associated impacts this will have on numerous aspects of remedy implementation ranging from construction duration (e.g. time required to install walls, and impacts to dredge production rates) to the overall net benefit and cost effectiveness relative to other means. EPA also continues to show figures that depict sheet piling in greater than 50 feet of actual water depth, which is technically infeasible. These figures also imply that sheet piles will be installed in the navigation channel, which would infeasibly obstruct vessel traffic. Sheet pile would also impact ongoing water dependent operations and nearshore fish migration does not evaluate whether sheet piles in the navigation channel could be permitted by USACE.*

*Because of the technical infeasibility of the use of sheet pile barrier walls, their consideration as a feasible technology for dredge water quality control measure should be removed from the FS.*

**EPA Position:**

EPA disagrees that the use of sheet piles has not been adequately evaluated relative to other control technologies and BMPs. Sheet piles are a representative engineered rigid control measure identified and evaluated for sediment dispersion control in the 2016 FS. However, that representative approach does not preclude other types of rigid control measures for consideration during remedial design. As stated in the 2016 FS, Appendix O, EPA agrees that depth can limit the use of suitable engineered options for controlling releases, and deep water depths can preclude the use of sheet piles. EPA assumes that engineered rigid containment will be utilized when NAPL was present in water depths less than 50 feet.

Engineered rigid control measures were evaluated holistically within the 2016 FS for their use in reducing or eliminating short-term releases of contaminants during construction and not on a location-specific basis. Thus, the 2016 FS does not present figures indicating design level logistical details regarding location and depth of engineered rigid control measures. Location-specific evaluations for feasibility of sheet pile versus other types of engineered rigid control measures, including placement within the navigation channel, were beyond the scope of evaluation of the 2016 FS. Details regarding sediment dispersion control and location-specific engineered rigid control measures will be determined during remedial design which is the appropriate time for those types of evaluations.

Alternative-specific costs for purchasing, installing and removing sheet pile walls are presented in Appendix G of the 2016 FS. The unit costs were developed by the LWG in the draft 2012 FS on a horizontal linear foot basis. Quantities for sheet pile lengths used

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

in the detailed alternative cost estimates and presented in the 2016 FS, Table D2.j (in horizontal linear feet), were holistically estimated for each alternative by encircling all PTW dredge and/or capped areas with silt curtains assumed for the remainder of dredged and/or capped areas.

See EPA's position to LWG's dispute issue 2b regarding rigid containment.

The determination of technical feasibility of engineered rigid control measures is highly dependent on site specific conditions. As stated in Appendix O of the 2016 FS, EPA agrees that depth can limit the use of suitable engineered options for controlling releases, and deep water depths can preclude the use of sheet piles. However, blanket elimination of the technology is not warranted. EPA assumes that engineered rigid containment will be utilized when NAPL was present in water depths less than 50 feet.

**LSS Dispute Issue 17 - Flawed evaluation used to determine whether PTW can be reliably contained**

*Notwithstanding Arkema's objection to EPA's definition of PTW, and assertion it is present offshore of the Arkema site, the approach used to determine applicable remedial technologies to address PTW in the draft final FS is flawed because it is based on a simplistic, overly conservative screening analysis and does not include standard engineering methods used to assess and ensure reliability. Additionally, EPA neglects to consider the current state of practice for reactive capping.*

*According to EPA, PTW is a concept used in the NCP to characterize contaminant source material (USEPA 1991). PTWs are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. In the 1991 guidance, EPA stated their expectation that PTW would be treated, wherever practical, because of current technical limitations of long-term reliability of containment technologies. The long-term reliability of containment of certain NAPL PTWs has improved through the development and implementation of reactive capping, as demonstrated by EPA (USEPA 2013). The draft final FS does consider and propose reactive capping but uses a flawed, simplistic screening analysis to limit its use through designating certain SMAs as PTW NAPL/NRC, reflecting those areas where purported NAPL is deemed not reliably contained (NRC). Furthermore, the draft final FS is not consistent with the EPA guidance on principal threat and low-level threat wastes (LTW) (USEPA 1991), as it does not differentiate PTW from LTW NAPL based on toxicity, mobility, and (realistic) reliability of containment, but uses NAPL and PTW interchangeably. For instance, for shallow areas it states that NAPL or PTW that is not reliably contained within an SMA would be dredged to the lesser of the RAL concentrations or 15 feet.*

*To determine the boundary for where PTW can be reliably contained, two limited capping options were modeled in Appendix D to determine the maximum concentrations of PTW material that would not result in exceedances of AWQC in the sediment cap pore*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*water after a period of 100 years. Contaminants modeled were chlorobenzene, dioxins/furans, DDx, naphthalene, PAHs, and PCBs. Appendix D contains the following errors or omissions:*

- The objectives of the analysis are not clearly identified. The document states “this appendix is evaluating whether or not PTW at the Site can be reliably contained under specific assumptions”. However, at the end maximum containable sediment concentrations of 320 µg/kg and 140,000 µg/kg for chlorobenzene and naphthalene are presented;*
  
- The two potential active cap designs modeled (thickness of capping layers and amount of active material in cap for a reasonably conservative approach and a more aggressive augmented capping approach) are not representative of the current state of practice for reactive capping and so cannot be used to determine the contaminant concentrations that cannot be reliably contained;*
  - o The reasonably conservative approach (12-inch active layer containing 5% activated carbon by weight) is not applicable for NAPL sites. The example site referenced (Berry’s Creek in New Jersey and Bailey Creek, Fort Eustis in Virginia) are likewise not NAPL sites. Additionally, Berry’s Creek represents a very small pilot-scale test of reactive cap technologies.*
  - o The more aggressive augmented capping approach (12-inch active layer containing 20% activated carbon by weight) is also not applicable for NAPL sites. Organoclay is a more applicable and effective amendment for NAPL site (McCormick Baxter and West Branch Grand Calumet River).*
  - o GAC may have a greater absorption capacity than organoclay on an equivalent weight basis with regards to some dissolved phase contaminants, but it can easily be fouled by NAPL.*
  
- The long term reliability of a reactive cap is a direct function of the thickness of the reactive layer and the amendment(s). A more reliable reactive cap with a thickness greater than 12-inches and consisting of a lower layer of organoclay and an upper layer of GAC should have been considered in Appendix D.*
  
- Maximum porewater concentration of chlorobenzene used as a continuous source term in the model is based on the relatively old Remedial Investigation (RI) database and is not representative of current conditions, let alone for the next 100 years. In addition, EPA has used data that was not collected pursuant to the RI. EPA has used reconnaissance data collected using a Geoprobe rig. The data are unacceptable for and cannot be used to represent porewater chlorobenzene concentrations. Therefore, the maximum porewater concentration EPA used is based on inappropriate data and needs to be replaced in the model. Since the RI data collection, a barrier wall and pump and treat system has been installed along the shoreline of the Arkema site. It is anticipated that any remaining dissolved-phase chlorobenzene left beneath sediments (stranded wedge along toe of riverbank) will continue to naturally attenuate. Furthermore,*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*maximum data are no appropriate for assessing engineering performance, including reliability. A more appropriate input parameter is the 90th percentile concentration.*

*• A range of seepage velocities were evaluated (0.3, 3, and 30 cm/day), representing the minimum, average, and maximum values measured at the Site. However, actual seepage velocities in SMA 7W are likely lower than 0.3 cm/day due to presence of barrier wall and pump/treat system.*

*EPA should revise the active cap modeling calculations to be transparent and clearly explain the assumptions in the model, model the active cap layers using current state of practice assumptions, utilize realistic long-term source concentrations in the cap model, and use a range of seepage velocities.*

**EPA Position:**

Consistent with the NCP and EPA guidance, PTW was identified based on a  $10^{-3}$  risk, source material (NAPL) within the sediment bed. As noted in “A Guide to Principal Threat and Low- Level Threat Wastes” (Superfund Publication 9380.06FS, November 1991):

Principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. They include liquids and other highly mobile materials (e.g., solvents) or materials having high concentrations of toxic compound

EPA expects to use treatment to address the principal threats posed by the Site, wherever practicable, consistent with the NCP (40 CFR §300.430) and EPA guidance. However, based on the technology assignment process, if sediment classified as containing PTW is located in an area designated for capping, then a reactive cap will be assumed for that area to meet the preference for treatment and meet surface water applicable or relevant and appropriate requirements (ARARs). As such EPA determined what PTW may potentially be reliably contained based on modelling representative site conditions and capping options to determine the maximum concentrations of PTW material that would not result in exceedances of human health based water quality criteria. While modeling indicates that there may be an increase in the potential to control the material, it is not deterministic that that will in fact be the case for all portions of the site. As such, the modeling information is useful as part of the nine evaluation criteria, but it not relevant to the determination of PTW.

The 2016 FS relied on location specific technology assignments to develop remedial action alternatives for evaluation in the detailed and comparative evaluation of remedial alternatives. The technology assignment process considered site specific information such as water depth, current and future navigation uses, PTW, contaminated groundwater plumes, structures, wind and vessel wake generated waves, sediment deposition rate, sediment bed slope, the presence of cobbles, rocks and bedrock, propeller wash, debris,

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

and the vertical extent of contamination. Consideration of these site specific factors was conducted in a technically appropriate manner.

EPA relied on observations of NAPL to identify areas where NAPL may be present and employed a site-specific capping model to determine whether COCs at the Portland Harbor site can be reliably contained. As mentioned in Section 3.2.2.2 of the 2016 FS “This is an appropriate model to make FS-level decisions and is sufficiently rigorous to be used for decision-making at the FS phase. More rigorous modeling may be conducted as needed in remedial design.” It should be noted that the identification of NAPL and not reliably containable material in sediments offshore of the Arkema site are not mutually exclusive. Rather areas identified as containing NAPL were also found to contain levels of chlorobenzene that were determined to be not reliably containable.

The 2016 FS also developed a series of generic cap designs that incorporate reactive materials. This includes the “significantly augmented reactive cap” that utilize organoclay mats and low permeability materials to contain NAPL and reactive caps that utilize particulate activated carbon (PAC) mixed with sand to a PAC concentration of 5 percent by weight to contain highly toxic PTW. These FS level cap designs are consistent with the application of reactive caps at contaminated sediment sites around the country including the McCormick and Baxter site in Portland, Oregon and the River Mile 10.9 removal action in Lyndhurst, NJ.

This comment misrepresents the cap designs utilized in the 2016 FS. The 2016 FS relies on a “significantly augmented reactive cap” for areas where NAPL will be left in place. The significantly augmented reactive cap relies on organoclay mats and low permeability materials to contain NAPL and consists of the following elements:

- Chemical Isolation Layer: 1-inch organoclay mat.
- Low Permeability Layer: 17-inch layer of fine grained sand or other low permeability material
- Physical Isolation Layer: 12 inches of sand.
- Stabilization Layer: 6 inches of armor stone.

Reactive caps are utilized for areas where highly toxic PTW will be left in place. As noted in the comment, activated carbon is not considered suitable for NAPL due to the potential for fouling.

Reactive caps rely on a 12 inch layer of sand and powdered activated carbon (PAC) at a concentration of 5 percent by weight to contain highly toxic PTW and consists of the following elements:

- Chemical Isolation Layer: 12-inch layer consisting of approximately 50 percent sand and 50 percent AquaGate+PAC.
- Physical Isolation Layer: 18 inches of sand.
- Stabilization Layer: 6 inches of beach mix or armor stone.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

For the significantly augmented cap, an organoclay mat that is effectively equivalent to four times the amount of activated carbon typically placed in a cap was conservatively assumed. The conservative assumption of a low permeability layer, COC degradation and no deposition were also used in order to contain the maximum possible contaminant concentration with this cap. The use of an organoclay mat and an upper layer of GAC (or PAC) may be considered during remedial design.

The model was used to estimate the maximum concentration of chlorobenzene that can be reliably contained using the significantly augmented reactive cap. The effects of the barrier wall and pump and treat system can be used during remedial design activities.

Any seepage velocities being influenced by the presence of the barrier wall and pump-and-treat system should be empirically collected prior to design for the construction of a cap based on site-specific criteria. The range of seepage velocities evaluated in Appendix D of the 2016 FS were selected to better understand contaminant fate and transport under a range of conditions.

The assumptions used for this analysis are outlined in the 2016 FS, Appendix D, Section D7.4 and Section D7.5, and are in line with current state of practice. A range of seepage velocities were evaluated (0.3, 3, and 30 cm/day), representing the minimum, average, and maximum values measured at the Site. As noted above, seepage velocities that consider the presence of the barrier wall and pump and treat system may be considered during remedial design. The assumptions used for this analysis are explained as follows:

- a 12-inch active layer with “active layer loading of the augmented cap of 0.48 lb/ft<sup>2</sup>/cm” was assumed which is four times the amount of activated carbon typically placed in a cap
- “a low permeability layer limiting seepage velocity to 0.3 cm/day was assumed” to represent a conservative value for seepage velocity
- degradation was assumed to incorporate effects of degradation of chemicals due to the long residence time in the cap
- “No sediment deposition on top of the cap” was conservatively assumed
- No consolidation was assumed to take place in the cap or in the underlying sediment

**LSS Dispute Issue 18 - Riverbank contaminants adjacent to the Arkema Site**

*PCBs are listed as a riverbank contaminant at Arkema, but have only been detected in small number of samples below the applicable screening levels (with one exception, one sample slightly exceeded a conservative bioaccumulative SLV). The FS references an attached riverbank database, but the database was not included. Consequently, LSS continues to have no way to verify any of EPA’s FS decisions regarding remediation of the river banks. Regardless, prior issues with EPA’s source control approach remain. Two key issues are (1) risk-based PRGs should not be established based on exposure pathways being evaluated as part of the upland source control evaluations under DEQ*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*and (2) that none of these upland media were evaluated in the BLRAs or RI. EPA's use of sediment PRGs for riverbanks, which were even applied to areas rarely submerged by the river and without considering fate and transport (e.g., attenuation), is technically unsupportable and inappropriate. Delineations of groundwater plumes and riverbanks, and a zero post-construction restoration time frame are arbitrary. There is a total lack of data and analysis as to what risk considerations are driving the specific remedial actions delineated (and therefore how such analyses will be refined in the design phase when further data/analysis is available) and what specific remedial actions will be implemented in which areas driven by those risks. This arbitrary delineation is then carried forward into the evaluation of alternatives and used to assess the relative effectiveness of alternatives. This appears to significantly bias the outcome of alternative selection.*

*Source control measures taken at the Arkema Site have largely eliminated the stormwater pathway from this site. Groundwater controls, namely the installation of a slurry wall and a groundwater extraction and treatment system designed to prevent migration from the uplands to the river, have eliminated the groundwater pathway.*

*The June 2016 FS fails to include a discussion of upland source controls that have been implemented as well as failing to include anything related to the performance of source controls in the remedial evaluations.*

*The FS report should be modified to include appropriate risk-based PRGs developed for riverbanks rather than sediments and should acknowledge and include a discussion of upland source control measures in the remedial evaluations.*

**EPA Position:**

See EPA position to LWG dispute issue 1q.

**LSS Dispute Issue 19 - Updates to risk assessments**

*The FS should include language for allow for changes in pre-design work, to allow for updates to risk assessments. For example, if sediment and/or fish tissue samples are collected which show concentrations less than target levels, then PRGs/RALs would need to be revisited. Similarly, if additional studies on benthic toxicity are conducted for a portion of the river, those results should be used to update the remedial footprint for RAO5. Several source control actions have been undertaken and completed since the RI dataset was collected. Thus, areas of the river, COCs and media previously shown to show unacceptable risk may no longer show risk. Thus, a remedy may not be necessary to address some or all RAOs where such changes have occurred. Furthermore, as noted above, background levels are not well defined based on the RI dataset and need to be updated and re-assessed to develop more robust background values. Because many of the COCs have PRGs based on or very close to background levels, as currently defined, an improved understanding background conditions is key to a successful remedy. Otherwise, predicted risk reductions, which are already minimal, will not be realized. The potential outcome is a high cost remedy which provides no public benefit.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Section 2.2 of the FS only states: “Achieving the above RAOs relies on remedial alternatives’ ability to meet final remediation goals/cleanup levels derived from PRGs. At this point, Table 2.2-1a-d provides PRGs that are based on such factors as risk, ARARs, and background. Section 2.2 of the FS also states “PRGs may be further modified through the evaluation of alternatives and the remedy selection process. Final cleanup levels will be selected in the Record of Decision.” Yet, there is no other mention of the process in the FS.*

*EPA should modify the FS to clearly describe data gaps and uncertainties that can be addressed during design, including listing anticipated pre-design and design studies, developing robust background values and using any new measured data, and the process for modifying PRGs and remedies based on these studies.*

**EPA Position:**

Within the main text of the 2016 FS there are 26 instances where collection of additional data to assist remedy design and flexibility in refining the remedy during the remedial design process is discussed. EPA is not aware of a prescriptive number of how many instances this must be mentioned before it may be considered sufficient. The data gaps and uncertainties that can be addressed during design, including anticipated pre-design studies, is appropriately discussed in the ROD, not in the FS. [See EPA’s *A Guide To Preparing Superfund Proposed Plans, Records Of Decision, And Other Remedy Selection Decision Documents* (OSWER 9200.1-23P), *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (OSWER Directive 9355.3-01), and *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (OSWER 9355.0-85)] Thus, modifications to the FS to incorporate this information are not appropriate.

**LSS Dispute Issue 20 - Evaluation of MNR**

*The Monitored Natural Recovery (MNR) evaluation is insufficient to support the alternatives evaluation. The FS continues to omit key components of an MNR evaluation as required by guidance (such as EPA’s 2005 sediment remediation guidance) including: 1) an adequate CSM; 2) appropriate evaluation of multiple lines of empirical evidence; and 3) a quantitative evaluation of natural recovery and the associated long-term (i.e., after “time zero”) outcomes of the alternatives. New concerns with this FS include:*

- *EPA added new information on bathymetry changes and fish tissue. In Section 3.6.1.3, EPA’s updated evaluation of fish tissue concentrations over time completely ignores 2012 data without any explanation.*
  
- *EPA states that, “Therefore, a minimum deposition rate of 2.5 cm/year was assumed as the criteria [sic] for effective MNR.” This criterion is obviously not used by EPA in the FS because the FS assumes MNR as the applicable technology for all areas outside SMAs (as opposed to applying MNR in just areas exceeding the minimum deposition rate).*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*Although we agree with the wide application of MNR, EPA's explanation of its MNR evaluation process is full of inconsistencies and errors.*

*• Rather than assuming an effective conceptual framework that will incorporate new information and adjust the assignment of MNR to specific areas during design, the FS focuses on minor challenges affecting one, of multiple, lines of evidence used to assess natural recovery rates (i.e. EPA emphasizes the challenge in assessing deposition rates for the shallow region using bathymetric data - given an assumed inability for survey boats to maneuver and obtain quality data.) In its biased presentation of this matter, EPA ignores multiple lines of evidence that can, and should, be used to reduce uncertainties during design and be used to refine technology assignments.*

**EPA Position:**

The Respondent does not provide any information as to why the CSM described in the RI Report produced by the LWG is inadequate. EPA significantly modified and approved the RI Report that meets the requirements of the NCP and EPA guidance and policy. Also, as stated in Section 3.6.1.3 of the 2016 FS, EPA did use the 2012 fish data in evaluating MNR. As stated in the 2016 FS, MNR is both deposition and dispersion; thus, MNR is applied to all low concentration areas, not just areas exhibiting a certain deposition rate. EPA looked at areas of deposition (see Appendix D8) to determine if enough deposition would occur in various areas of the Site using the deposition rates for each 10 ft x 10 ft pixel to mix and reduce remaining sediment concentrations to acceptable concentrations. As stated above, the 2016 FS developed alternatives based on currently available information and does not discuss what should be in a ROD for future evaluation.

**IV. UPRR DISPUTE STATEMENT RESPONSE**

**UPRR Dispute Issue 1 – Overarching Concern**

*Under the Comprehensive Environmental Response Compensation and Liability Act ("CERCLA"), 42 U.S.C. § 9601 et seq., and its implementing regulation, the National Oil and Hazardous Substances Pollution Contingency Plan ("NCP"), 40 C.F.R. Part 300, EPA is required to use a specified framework and particular criteria for identifying and evaluating cleanup alternatives to address unacceptable risks posed by hazardous substances. EPA's national sediment guidance documents explain how the NCP framework should be utilized at sediment megasites.*

*While EPA has substantial discretion in how it evaluates cleanup alternatives and identifies a preferred alternative using the nine criteria for FS evaluations set forth in 40 C.F.R. § 300.430(e), the cleanup goals must be achievable through the implementation of the selected cleanup. Contaminated Sediment Remediation for Hazardous Waste Sites, December 2005 ("Sediment Guidance").*

*Such is not the outcome of the FS for the Site. In failing to comply with requirements for evaluating cleanup alternatives in a FS, as described in more detail below, EPA Region*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*10 has generated a preferred alternative that requires attainment of a total PCB cleanup goal that is not achievable and sustainable, is far more disruptive than described by EPA, will take much longer to implement than predicted by EPA, will likely cost significantly more than estimated by EPA, and is therefore not cost-effective as required by the NCP. Further, the FS does not identify which areas currently pose the highest risk and should be prioritized for remediation.*

*This result is inconsistent with one of the fundamental principles of the Superfund program as expressed in the NCP Preamble: "... this process [the remedy selection process] considers the full range of factors pertinent to remedy selection and provides the flexibility necessary to ensure that remedial actions selected are sensible, reliable solutions for identified site problems." 55 FR 8700 (March 8, 1990).*

*The LWG's draft FS fulfilled the requirements of the law and EPA guidance, proposing a workable, common sense cleanup. EPA's unnecessary and inappropriate takeover of the FS from the LWG has diminished the quality and value of the FS. The LWG's 2012 draft FS incorporated reliable science, provided the required comparative analysis of alternatives, and relied on realistic estimates of cost and time necessary to perform work. The LWG was prepared to fully engage with EPA and resolve EPA's comments and concerns in order to produce a report that provided a credible basis for EPA's selection of a remedy that conformed to CERCLA, the NCP, and EPA guidance. EPA's unwarranted deviation from the RI/FS process agreed to by EPA in 2001 was an abuse of discretion and will not lead to an effective and timely cleanup.*

*Cleanup projects that are estimated to cost hundreds of millions, if not billions, of dollars must be evaluated and selected based on how effectively they will perform in the physical world. At this Site in particular, the impact of fast-flowing river dynamics on the schedule and cost of remediation are not sufficiently evaluated in the FS.*

*Union Pacific disputes the FS as a whole because it leads to a proposed cleanup project that has not been sufficiently evaluated as required under the NCP and has no realistic chance of being implemented as described by EPA. Union Pacific also disputes the determination that certain sediments in the vicinity of its railyard (the "Albina Yard") require remediation. Further specific bases for Union Pacific's dispute of the FS are set forth in the paragraphs below.*

**EPA Position:**

See EPA's position to LWG's requested relief #2.

**UPRR Dispute Issue 2 - EPA's PCB Cleanup Goal is Not Achievable**

*The preliminary remediation goal ("PRG") for total PCBs in the FS is nine parts per billion ("ppb"). The basis for this value is that it is the "background" value determined by*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*EPA in the RI. The cleanup goal for PCBs is highly significant because PCBs are driving over 90 percent of the risk at the Site.*

*Union Pacific disputes both that the background number is achievable at the Site and that it should be used as a cleanup goal. Neither CERCLA nor the NCP authorizes EPA to select cleanup goals that are not achievable. EPA's guidance states the FS should confirm that cleanup goals are achievable by the sediment cleanup itself. Sediment Guidance, page 2-15.*

*In section 7.2.2 of the RI, the upriver reach of the lower Willamette River extending from RM 15.3 to 28.4 was selected as the reference area for determining PCB background sediment concentrations. Although separated from the Site by anywhere from four to 17 miles, EPA chose this area because it is considered broadly representative of the upstream sediment loading to Portland Harbor. Based on its evaluation of data from this reference area, EPA determined the background concentration for PCBs for the Site is nine ppb.*

*The Lower Willamette Group disputed how EPA evaluated the data in determining background. In his letter dated March 24, 2015, denying the dispute, Richard Albright, the then current Director of the Superfund program in Region 10, wrote at page 16:*

*I would like to emphasize that as noted by EPA's Response at p. 24, there are sources of contamination outside of the Site - both upriver of the Site and within the downtown reach - that may affect the ability of the cleanup efforts within the Site to equilibrate to the selected cleanup level regardless of whether the cleanup level is based on risk, regulatory standard or background. In this regard, the Site is similar to other urban sediment sites which CERCLA addresses like the Lower Duwamish Site in Seattle.*

*If the Site cannot "equilibrate" to nine ppb, the cleanup level will not be achieved by the sediment cleanup action. The LWG submitted comments to EPA explaining how equilibrium, not background, should be used to establish PRGs and evaluate FS alternatives. The final FS appears to disregard all of this information.*

*Perhaps the most reliable certainty at the Site is that the Lower Willamette River continuously flows in one direction, from south to north, without pause or deviation. As part of the flow, the river carries sediments, much of which are deposited within the Site. Equilibrium is the result, in part, of concentrations of contaminants in the incoming sediments from upstream. As strongly suggested by Rick Albright, active remediation within the Site cannot achieve concentrations lower than that of the equilibrium level.*

*The LWG estimated equilibrium concentrations based on existing RI empirical data, including deposited surface sediment data (from depositional areas upstream of the Site and from depositional areas within the upper reaches of the Site but apart from known source areas), sediment trap data, upstream suspended sediment data, and smallmouth bass fish tissue data from 2002, 2007, and 2012. The result of the LWG's evaluation of*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*empirical data, which was presented to EPA in August 2014, is that the equilibrium value for total PCBs should be 20 ppb. The LWG advised that EPA should not select risk-based PRGs below equilibrium values, including for PCBs. EPA's failure to do so, and failure to explain why the FS does not incorporate any evaluation of equilibrium, is inconsistent with the reasoning of its own former Director and an array of real-world data, and undermines the presumption that its proposed cleanup goal for total PCBs is realistically achievable.*

*Further, EPA's failure to use reliable models to reasonably predict when cleanup goals will be attained is another significant omission in the FS. In effect, EPA has not included any credible information in the FS indicating that its cleanup goals, particularly for PCBs, are actually achievable and sustainable over the long-term at the Site. The importance of models (e.g., sediment transport model and bed composition model) in making cleanup decisions at sediment sites is explained in detail in the Sediment Guidance, section 2. 9. Such models are generally used at large sediment sites (e.g., Lower Duwamish and Lower Passaic sites), but were not used here.*

*Union Pacific disputes both that the cleanup goal for PCBs is achievable at the Site and that it is consistent with the NCP.*

**EPA Position:**

While UPRR alleges that EPA chose the upriver reach from RM 15.3 to 28.4 as the “reference area,” the administrative record for this site clearly indicates that the LWG chose this area, in consultation with EPA, DEQ, and the tribes. EPA does not discount the presence of possible in-water PCB sources upstream of the current Site boundary at RM 11.8, or of potential upland sources. However, the assumption in the 2016 FS is that those sources would be controlled and DEQ has represented that it will have significant upstream sources addressed. [See DEQ’s 3/25/16 updated summary report (AR Doc ID # 1000019892), Section 4.7, and their presentation to the NRRB, (AR Doc ID 100002728) at Slide 16.] It is EPA’s expectation that potential sources will be controlled through DEQ’s source control efforts under State authority, or if necessary by EPA using its CERCLA authority. Thus, background concentrations as represented by the deposited sediment concentrations exhibited in the “reference area” remain the best predictor of achievable cleanup goals for the Site, particularly given the unreliable nature of the predictions from the LWG’s sediment fate and transport model (see 2016 FS Section 4.1.2 and Appendix H). The sediment data for Portland Harbor is replete with a large signature of PCB concentrations at or less than the PRG of 9 ppb, which would not be possible if the LWG’s “equilibrium” theory were credible (Figures 5.2-1 and 5.2-2 in the final RI report). In addition, EPA notes that the assertion that “the most reliable certainty at the Site is that the Lower Willamette River continuously flows in one direction, from south to north, without pause or deviation” is not true and is directly contradicted by information presented in the LWG’s own reports submitted to EPA, which clearly note that Portland Harbor is subject to tidal influence and also documents flow reversals from the Columbia River backing up the Willamette during flooding or high water events through at least the downtown reach. Lastly, UPRR overstates that

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

EPA's sediment guidance emphasizes the "importance of models"; a more correct characterization of the guidance is that the models can be useful. However, the lack of the proper time-series data, as acknowledged in the LWG's draft 2012 FS, prevented validation of a sediment transport model for Portland Harbor.

**UPRR Dispute Issue 3 - Risk Management is Absent from FS Evaluation**

*Another fundamental flaw in the FS is the absence of credible risk management. Risk management in the Superfund program requires the consideration of the advantages and disadvantages of cleanup alternatives and a balancing of trade-offs. This analysis includes an evaluation of the uncertainties at the Site, including uncertainties in the reliability of the exposure data used to identify the risks. 40 C.F.R. § 300.430(e)(2)(i)(A)(4). Further, as noted in the NCP Preamble, "[t]he likelihood of the exposure actually occurring should be considered when deciding the appropriate level of remediation, to the degree that this likelihood can be determined." 55 FR 8710 (March 1990).*

*As described in the Sediment Guidance: "A risk management process should be used to select a remedy designed to reduce the key human and ecological risks effectively." Sediment Guidance, page 7-1. It is telling that the term "risk management" is never used in the FS.*

*At Portland Harbor, the risk assessments, particularly for human health, are built on a cascade of conservative assumptions regarding exposure and durations. Unacceptable risks to various consumers of fish are based on questionable assumptions of how many fish people eat, from which areas of the river, how the fish are cooked, and for how many years. Contrary to the NCP, the assumptions were not placed in an overall estimate that is conservative but within a realistic range of exposure as required by the NCP. NCP Preamble, 55 FR 8710. Further, the assumptions used at Portland Harbor are not compared to assumptions used at other sediment megasites (i.e., nowhere is there an explanation why people are more exposed to certain kinds of risk in Portland than they are in Seattle or Newark, for example).*

*Of equal importance is that EPA's FS fails to document how the risk assumptions have been considered when evaluating alternatives. The FS describes what appear to be highly exaggerated risks at the Site. For example, the acceptable consumption rate is 6 fish meals every 10 years. EPA does not provide backup for how meals per 10 years were calculated or how it is consistent with the baseline risk assessment. Nor does EPA clarify whether resident fish caught from any location within the 10-mile river contribute to potential excess risk. In the absence of such information in the FS, it is not apparent that the reliability of the exposure assumptions has been sufficiently considered (i.e., whether an important element of risk management has even been conducted).*

*Finally, the FS does not identify which areas currently pose the highest risk and should be prioritized for remediation. At a 10-mile Site that, according to the FS, encompasses nearly 300 acres requiring active remediation and likely close to 20 years to perform the*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*cleanup, it would seem necessary and prudent to establish a basis for prioritizing and sequencing the cleanup of the higher risk areas. EPA's failure to do so is an indication that it is not effectively managing the risk.*

*Union Pacific asserts EPA has failed to comply with regulations and guidance because the FS fails to document that EPA included a legitimate risk management step in its evaluation and decision-making process. The absence of risk management means EPA has not demonstrated the preferred alternative represents the most appropriate solution for the Site.*

*Union Pacific disputes that the FS incorporates risk management as required by the NCP.*

**EPA Position:**

UPRR's issues with the BHHRA and the exposure assumptions used were the subject of a previous formal dispute by the LWG under the AOC. EPA's position and determination of the appropriateness of the assumptions used for the Portland Harbor Site was documented in the final ECL Director decision and supporting administrative record. **[AR Doc ID # 1432316 and 715198]**

In the 2016 FS, EPA used equations B3-15 and B3-16 to calculate fish meals and solved for the consumption rate (CR). These are the same equations used to establish risk in the BHHRA.

Lastly, regarding UPRR's assertion that the FS was not clear about how risk management was applied in evaluating the alternatives, the NCP and EPA guidance state that risk management should be used in selecting a remedy. EPA did not select a remedy in the 2016 FS; thus, did not discuss risk management in selection of a remedy. The Preferred Alternative was discussed in the Proposed Plan and the final remedy will be selected in the ROD.

**UPRR Dispute Issue 4 - The FS Requires More Sediment Removal Than Necessary**

*"Principal threats are characterized as waste that cannot be reliably controlled in place, such as liquids, highly mobile materials (e.g., solvents), and high concentrations of toxic compounds (e.g., several orders of magnitude above levels that allow for unrestricted use and unlimited exposure)." NCP Preamble at 55 FR 8703.*

*In the FS, EPA has designated large areas of sediments with relatively low concentrations as principal threat waste ("PTW") (e.g., above 200 ppb total PCBs) that must be removed from the Site, including near Union Pacific's Albina Yard. However, the FS fails to explain satisfactorily how sediments in these large areas are highly mobile or highly toxic and how they cannot reliably be contained in place.*

*The FS does not contain a credible conceptual site model that identifies the extent to which certain areas of sediments are "highly mobile" and need to be removed. Most*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*areas of the Site are depositional, meaning that sediments in these areas are stable and likely to remain in place in the future. In many cases, where contaminant concentrations in surface sediments in these areas represent an unacceptable risk, such sediments can be reliably contained in place.*

*Nor are the PCB levels in the river "highly toxic". In the risk assessment, EPA identified unacceptable risks based on fish consumption, which is an indirect exposure pathway (i.e., people are not eating contaminated sediments). Consistent with acceptable risk assessment methodology, exposure assumptions were averaged over time and space to best represent potential indirect exposure to people eating fish. The exposure units for the fish consumption pathway ranged from site-wide to individual EPA river miles, depending on the home range of the fish species.*

*In its designation of PTW, however, the FS disregards acceptable methods for assessing indirect risk and identification of PTW thresholds. In the FS, any sediment that exceeds 200 ppb PCBs is deemed PTW. The FS does not explain or justify why sediment at such a relatively low concentration is "highly toxic" (i.e., several orders of magnitude above levels that allow for unrestricted use and unlimited exposure). At many other sediment megasites around the country, EPA's cleanup level for total PCBs is 1 part per million. Sediment containing PCBs at 200 ppb is one-fifth of what is considered an acceptable cleanup level at these other sites. The FS's designation of "highly toxic" material at Portland Harbor is without basis, contrary to policy and practice elsewhere, and clearly not reasonable.*

*Further, as the LWG has explained to EPA, EPA's decision to cap, rather than remove, more highly contaminated sediments associated with the McCormick-Baxter site is inconsistent with its current position on treating principal threat waste elsewhere at the Site.*

*Union Pacific disputes EPA's designation of principal threat waste at the Site.*

**EPA Position:**

See EPA position to LWG dispute issue 2c.

EPA did not establish a requirement for removal of principal threat waste in the 2016 FS. Technology assignments were made in the 2016 FS based on area-specific environmental conditions discussed in Section 3 of the 2016 FS. Contaminated sediment identified as principal threat waste was only further evaluated for treatment as discussed in both the NCP and EPA guidance.

**UPRR Dispute Issue 5 - The FS Substantially Underestimates the Impacts of Performing, and the Time and Cost to Perform, the Preferred Alternative**

*One of the key FS evaluation criteria in the NCP is short-term effectiveness, which requires consideration of the effects of the alternative during the construction and implementation phase until remedial response objectives are met. 40 C.F.R.*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*§300.430(e)(9)(iii)(E). At sediment sites, short-term risks associated with capping and dredging may include potential contaminant releases during such operations (which may increase fish tissue concentrations) as well as accidents to workers, disruptions to business and recreational uses, and other impacts to the community (e.g., from light, noise, and air emissions). Sediment Guidance, at page 7-9. At a site where the cleanup will take many years to perform, a realistic evaluation of the time to perform the cleanup also needs to be incorporated into the evaluation of short-term impacts.*

*The FS does not include a reasonable quantification of the above-described short-term impacts, such as realistic estimates of the extent of dredge releases (e.g., water quality impacts). For each more aggressive alternative, the FS simply says the short-term impacts will be "greater."*

**EPA Position:**

There is nothing in EPA guidance (1998 or 2005) that requires quantification of short-term impacts. The guidance states that these impacts should be identified and the trade-off between alternatives discussed. The impacts are the same for all alternatives (except the no action alternative), the only difference is that the impacts are longer due to the increased construction duration with each alternative. Section 4.3.5 of the 2016 FS discusses the trade-offs for short-term effectiveness between alternatives. EPA states that the impacts for any alternative will be for 4 months per year and last the duration of the construction project. EPA quantified the construction period of each alternative and as the construction of the project increases, so would the impacts.

*Moreover, the NCP requires not only an assessment of individual alternatives against each of the nine criteria but also "a comparative analysis that focuses upon the relative performance of each alternative against those criteria." 40 C.F.R. § 300.430(e)(9)(ii). The so-called comparative analysis in the FS is oversimplified and does not attempt to meaningfully consider the trade-offs between increasing short-term impacts and the alleged benefits of more expansive dredging and capping requirements. If, for example, the water quality impacts (and associated impacts to fish tissue concentrations) from dredging are increasingly significant as the extent of dredging and capping increases, then there should be corresponding increases in the benefits from performing such increasingly more aggressive approaches. However, the FS does not include a credible explanation of how the preferred alternative's combination of active remediation and monitored natural recovery achieves cleanup goals in a substantially shorter time than less aggressive alternatives using a different combination (i.e., more monitored natural recovery). The required balancing of trade-offs under the NCP is conspicuously absent from the FS.*

**EPA Position:**

The comparative analysis conducted in the 2016 FS is consistent with the requirements of the NCP and EPA's guidance (cite to FS and sediment guidance). Increases in fish tissue concentrations due to dredging would only occur during the four month construction period. The increases would be localized to where the dredging occurs and would be far less

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

than the exposure during the high flow periods. Longer periods of dredging result in longer exposure in the site as a whole, as discussed in the 2016 FS, but tissue concentration would not increase because of the localized nature of the dredging and home range of the fish. Since all the alternatives include dredging in the same localized areas of the Site, the effects from dredge releases would be fairly indistinguishable between alternatives. At other sites, fish tissue concentrations have been shown to increase during dredging operations and then decrease substantially within a year of construction completion.

Respondents are referring to remedy selection criteria. A preferred alternative is not selected in the 2016 FS. The preferred alternative is discussed in the Proposed Plan, which is not subject to the dispute provisions under the AOC.

*In addition, the FS is wildly optimistic about the estimated time to perform each of the alternatives. In October 2016, the Port of Portland ("Port"), which has extensive experience with dredging projects, participated in a meeting with Jim Woolford, the head of EPA's national Superfund program, and explained that EPA's estimates of construction duration and cost were not reasonable and needed to be revised. On October 13, 2015, the LWG provided Mr. Woolford a memo which incorporated the Port's analysis (Enclosure 1). The FS fails to incorporate the Port/LWG's estimates and does not explain why it disagreed with them. Based on the memo, which incorporated the Port's real-life experience with dredging projects, it is very likely that the magnitude and duration of short-term impacts associated with the cleanup are substantially underestimated in the FS.*

**EPA Position:**

See EPA's position to LWG's dispute issue 1f.

*Further, as noted in section 2 above, EPA's failure to use reliable models to predict when cleanup goals will be attained is a fundamental flaw in the FS. For example, Page ES-16 of the FS states as follows: "Alternative I achieves more interim targets than Alternative D and is therefore more reliable in achieving PRGs and RAOs in a reasonable time frame because it relies less on natural processes."*

*But there is no information in the FS that supports the apparent assertion that Alternative I will achieve PRGs and RAOs more quickly than Alternative D. In the absence of a reasonable basis to compare the time frames in which the cleanup goals will be attained, the trade-offs between increased short-term impacts and the long-term benefits of the cleanup cannot be made as required under the NCP.*

**EPA Position:**

As stated in the 2016 FS, no reliable model of the lower Willamette River exists because Respondents did not collect data necessary to support development of a reliable model. If respondents wanted to use a reliable model, then they should have collected the necessary data identified in EPA guidance (2005) to support the development of a reliable model.

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

Further, EPA’s guidance does not require that a model be used, acknowledges that the use of any model in this type of system is highly unreliable in estimating recovery time frames, and only states that models are helpful in relating one alternative to another. There is no model that has the ability to predict with any certainty that these processes will occur in precisely some time frame. Models can only be used to show how alternatives perform relative to each other.

EPA has enough information in the CSM to understand that MNR processes are occurring in the lower Willamette River. Cleaner sediments from upriver continue to move into the Site, mix with the contaminated sediment, and transport to the Columbia River and out to the ocean. There is very little area within the Site that is constantly depositional (see 2016 FS Appendix D8), thus MNR is going to happen through deposition, mixing and dispersion. Logically, if there is a lower residual concentration in an area of the Site, then it will take less deposition, mixing and dispersion, and thus, less time, to reduce the contaminated sediments concentrations in order to reach the desired remediation goals. Since each of the Alternatives A through H progressively increase in the area capped or dredged, the remaining sediment concentrations would be progressively lower, as shown in the following example:

	Alt A	Alt B	Alt C	Alt D	Alt E	Alt F	Alt G	Alt H
Acres cap/dredge	0	95	117	177	269	505	756	2,167
PCB SWAC (µg/kg)	208	74	NA	56	40	23	17	9

(values taken from 2016 FS Tables 3.8-3 and J2.3-1)

Since MNR is through dilution and the rate would be the same for all alternatives, the lower the post-construction SWAC, the faster the dilution to the desired goal would be. For example, if the dilution rate was 10 µg/kg per year, it would take 20.8 years for Alternative A to reach the goal, 7.4 years for Alternative B, 5.6 years for Alternative D, etc. However, the actual dilution rates vary greatly throughout the site and are currently unknown, so a quantification of the actual dilution rates and times cannot be quantitatively computed with any accuracy. Thus, this evaluation could only be made qualitatively.

*Another significant omission in the FS is the absence of information to support the statutory determination of cost-effectiveness. As explained in the dispute letter submitted by a group of AOC signatories, significant categories of costs are either underestimated (e.g., engineering design, waste processing, water treatment, sheet pile barriers) or*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*completely absent (e.g., pre-design investigation, agency oversight, and Oregon Department of State Lands fees for access, leases, and easements).*

*Second, the FS fails to examine and compare the relative magnitude of cost to effectiveness of each alternative individually and the cost and effectiveness of alternatives in relation to one another. See NCP Preamble at 55 FR 8728.*

**EPA Position:**

See EPA's position to LWG's dispute issue 2b.

*The LWG has submitted many comments to EPA about deficiencies in the draft FS. Most of the deficiencies remain unaddressed. Issues associated with the evaluation of shortterm effectiveness, cost, and time are among significant concerns. However, just these concerns alone demonstrate a substantial weakness in the required evaluations in the FS and significantly impair any representation by EPA in the FS that the preferred alternative represents the best balance of the cleanup evaluation criteria.*

*Union Pacific disputes that EPA's evaluation of short-term impacts, cost-effectiveness, and time for construction of the cleanup are reasonable and in accordance with the NCP.*

**EPA Position:**

EPA considered all the issues previously raised by the LWG, and addressed all the issues raised by the LWG that needed to be addressed. Although the LWG may not agree with EPA's final decision on a particular issue does not mean that EPA did not address their issues.

**UPRR Dispute Issue 6 - Sediments Near Albina Yard Do Not Require Cleanup**

*The FS preferred alternative identifies two areas of sediments between RM 10 and 11 that EPA has identified for cleanup, purportedly due to exceedances of the PCB remedial action level ("RAL"). EPA also identified these areas on Figure 3.2-3 as containing principal threat waste. This area of the Site is near Union Pacific's railyard at Albina Yard. Union Pacific disputes this determination, particularly the area from approximately RM 10.7 to RM 11 where there are no exceedances of the applicable RAL in surface or subsurface samples of sediments.*

*EPA's potential cleanup area near RM 10.7 appears to be based on a PCB exceedance in soil at one location on a 900-foot stretch of the riverbank. EPA included riverbanks as part of its draft FS evaluation of alternatives, but did not identify Albina Yard as a site with "known contaminated riverbank" in section 1.2.3.5 of the FS.*

*Moreover, in its Final Remedial Investigation/Source Control Measures Evaluation Report for Albina Yard dated November 2010, which was reviewed and approved by Oregon DEQ, Union Pacific determined that the riverbank near Albina Yard had a low potential for erosion because it was highly vegetated and stabilized with rock/rip rap. Because PCB concentrations in the sediments are below the applicable RAL, and the*

Appendix A  
EPA Responses to Dispute Issues  
12/27/16

*riverbank is stable, this area of sediments should not be included as a potential cleanup area. Certainly, the FS contains no explanation for this area's inclusion as a potential cleanup area, much less as an area containing principal threat waste.*

*Union Pacific disputes the apparent determination that sediments near RM 10.7 require remediation and, for the reasons explained in detail in section 4 above, the designation of such sediments as principal threat waste.*

**EPA Position:**

The 2016 FS does not identify a preferred alternative. Further, EPA only developed SMAs based on extrapolations of existing sediment data that exceeded RALs, not river bank data. As Respondents point out, the river bank at Albina is not listed as contaminated. The SMA Respondent refers to is an artifact of the computer interpolation process, like many of the other small areas on the site. Because boundaries were not used in the computer interpolation process, this SMA is actually based on the high concentration sample data upstream from that location. EPA confirmed that there are not currently any samples in this cove that exceed RALs until more instream away from the shore at the Alternative H level, which is why there is an SMA strip outside the cove. The 2016 FS is not a design document and the footprints of the SMAs are based on extrapolations of RI/FS data, not design level data, and should not be used as absolute boundaries for SMAs. They are merely to identify at this stage of the process the cost estimates of remedial technologies to be used at the site in order to conduct a comparative analysis. Sampling conducted in remedial design will determine the boundaries for SMAs for active remediation.

**UPRR Dispute Conclusion**

*Sediment megasites like the Portland Harbor Site are extremely challenging -challenging to characterize the contamination and the dynamics of the river system, challenging to identify what are the significant risks, and challenging to evaluate alternatives to reduce such risks. Union Pacific appreciates the hard work, resources, and dedication EPA has devoted to the Site prior to and since the Site was added to the National Priorities List in 2000.*

*Nonetheless, Union Pacific is concerned that because EPA's FS does not comply in significant ways with regulatory requirements and guidance recommendations for sediment megasites, EPA's description of a preferred alternative is not realistic and will not achieve protection of human health and the environment for a reasonable cost and within a reasonable time frame. Union Pacific looks forward to further communication with EPA as its dispute of the FS is considered by EPA.*

**EPA Position:**

EPA has responded to the specific issues raised by Union Pacific. The 2016 FS was developed with EPA's experts at headquarters and reflects feedback and the support provided overall on the content and analysis contained in the 2016 FS, as well as recommendations made by EPA's expert panels for CERCLA remedies and sediment

sites (NRRB and CSTAG). Union Pacific has not provided any specific or credible evidence to support that the FS does not comply with the NCP and EPA guidance.

Contaminant	CAS RN	BERA	BHHRA	Identified as a COC	Rationale for Including/Eliminating
Acenaphthene	83-32-9	X		Y	Evaluate as PAH
Acenaphthylene	208-96-8	X		Y	Evaluate as PAH
Aldrin	309-00-2	X	X	Y	Human health: shellfish
Aluminum	7429-90-5	X		N	Not ecologically significant
Ammonia	7664-41-7	X		N	Ammonia only has an HQ=3 based on FPM, which does not reliably predict sediment toxicity for individual contaminants.
Anthracene	120-12-7	X		Y	Evaluate as PAH
Antimony	7440-36-0	X	X	N	Infrequent and/or anomalous detections in fish
Aroclor 1254	11097-69-1	X		N	Evaluate as PCBs
Arsenic	7440-38-2	X	X	Y	Human health: beach, sediment, water, fish/shellfish Known groundwater plumes at site.
Barium	7440-39-3	X		N	Not ecologically significant
Benzene	71-43-2	X		Y	Known groundwater plume at site.
Benzo(a)anthracene	56-55-3	X	X	Y	Human health: beach, sediment, water, fish/shellfish Evaluate as cPAH and PAH
Benzo(a)pyrene	50-32-8	X	X	Y	Human health: beach, sediment, water, fish/shellfish Evaluate as cPAH and PAH
Benzo(b)fluoranthene	205-99-2	X	X	Y	Human health: beach, sediment, water, fish/shellfish Evaluate as cPAH and PAH
Benzo(g,h,i)perylene	191-24-2	X		Y	Evaluate as PAH
Benzo(k)fluoranthene	207-08-9	X	X	Y	Human health: beach, sediment, water, fish/shellfish Evaluate as cPAH and PAH
Benzyl alcohol	100-51-6	X		N	Not ecologically significant
Beryllium	7440-41-7	X		N	Not ecologically significant
Bis(2-ethylhexyl) phthalate (BEHP)	117-81-7	X	X	Y	Human health: fish Ecologically significant contaminant
Cadmium	7440-43-9	X		Y	Ecologically significant contaminant
Carbazole	86-74-8	X		N	Not ecologically significant

## **I1. INTRODUCTION**

---

An evaluation of the uncertainties in predicted post-construction surface sediment COC concentrations was conducted, consistent with the recommendation provided the joint National Remedy Review Board/Contaminated Sediments Technical Advisory Group Comments on the proposed remedy (EPA 2015).

Because predictions of post-construction SWACs are based on a sample from the population of contaminated sediments, statistical uncertainties are unavoidable. In addition, because most remedial investigation data are based on a mixture of sampling designs, some of which are spatially biased accurate estimates of spatial averages must generally be based on weighted averages which are intended to counter the effects of spatially biased sampling designs. In geostatistics this is referred to as de-clustering the data (Isaaks and Srivastava, 2005).

The Portland Harbor FS, data were declustered by first interpolating the concentrations to a 10-foot by 10-foot regularly spaced grid, followed by averaging the values on these grid nodes. This approach based on natural neighbor interpolation has been found to perform reasonably well for reducing bias in SWAC estimates when they are based on a combination of biased and unbiased sampling designs (Kern et al. 2009). The natural neighbor interpolation was also used as a basis to forecast performance of a range of remedial alternatives based on actions taken in areas with the highest interpolated concentrations—referred to as hill-topping. This report documents an evaluation of the uncertainty in these predictions of remedial effectiveness using nonparametric geostatistical procedure known as conditional simulation using the P-field method (Srivastava, 2005).

## **12. METHODS**

---

### **12.1 DECLUSTERING METHOD SENSITIVITY**

---

Prior to conducting the conditional simulation analysis, four declustering techniques were tested to gain an understanding of the sensitivity of SWAC estimates to declustering methods. Methods that were tested included; 1) Thiessen polygons, 2) polygonal declustering, 3) stratified sampling based methods and 4) natural neighbor interpolation.

### **12.2 FUTURE CONDITION**

---

Uncertainty in predicted future condition was evaluated using two approaches; 1) considering basic mathematical constraints relating percentage area remediated, percentage reduction in SWAC and the ratio of remediated to unremediated areas, and 2) using a spatial Monte-Carlo approach to directly estimate confidence limits on post remedial SWAC under a range of remedial action limits (RALs). The first approach is a diagnostic providing a relative understanding of the demands that may be placed on the resolution of the delineation of deposits relative to experiences at other Superfund Mega Sites. The second approach provides a more direct evaluation of the expected remedial performance, under the combination of existing circumstances, including deposit complexity and level of sampling resolution.

#### **12.2.1 Mathematical Constraints on Remedial Alternatives**

Future condition under selected alternative scenarios was evaluated by considering basic mathematical constraints on the relationships between proportion reduction in post remedial SWAC, the percentage of area remediated, and the ratio of concentrations in remediated to unremediated areas. The constraints are based on equations in **Figure I-1** and provide remedial managers with a relative understanding of the potential level of resolution necessary to achieve remedial targets. In particular, when the remedial footprint is small and the targeted reduction in concentration is large, the ratio of average concentration in remediated areas must be much greater than that in unremediated areas. This will be feasible, only when high concentration deposits are well-consolidated and easily delineated, or with high density sampling providing highly resolved delineation of otherwise unconsolidated complex depositional patterns.

#### **12.2.2 Conditional Simulation**

Conditional simulation is a computer intensive resampling method analogous to bootstrap resampling, with the added constraint that rather than randomly selecting individual sample values, whole concentration maps are randomly selected and analyzed (**Figure I-2**). These maps can be thought of as a deck of cards, each of which interpolates the sample data and is also consistent with the spatial variation observed in

the sample. The analysis proceeds by randomly selecting one of many equally likely maps to which proposed remedial strategies are applied. The results for each randomly selected map are summarized, providing a means to propagate spatial variation and uncertainty through complex calculations, linking uncertainty in maps with uncertainty in SWAC predictions.

The technique takes into account the spatial uncertainty in mapped surfaces, and is spatially scalable and also accounts for uncertainty in the delineation boundaries. Uncertainty calculations help to quantify the effects of the situation where some contaminant concentrations within the RAL footprint are less than the RAL, as well as the when some concentrations outside the footprint may be greater than the RAL. These types of errors are assumed negligible when forecasts are based purely on a single smooth surface which can lead to inaccurate evaluations, usually biased toward overstatement of remedial benefit. This analysis provides an assessment of how these uncertainties accumulate in the post remedial SWAC predictions.

#### **Detailed P-Field Simulation Procedure (Optional Reading)**

The P-field simulation method involves three primary steps; 1) defining conditional cumulative distributions for COCs at each 10 by 10 foot grid cell, 2) simulating a spatially correlated normally distributed random variable for each grid cell, and 3) transforming the normally distributed variable to the original COC scale by identifying the percentile of the COC distribution with corresponding percentile of the simulated normal random variable at each grid cell. The cumulative distributions represent narrower ranges near sample values and wider ranges far from sample values, causing the simulated surfaces to match measured values at the sampled locations, whereas they may vary relatively widely in areas that are distant from sampled locations.

The conditional cumulative distribution functions were estimated using a nonparametric approach based on natural neighbor interpolation approximating the indicator kriging method that is typically used to estimate cumulative distribution functions. Estimating conditional distributions requires interpolation of a range of binary (0 or 1) indicators defined based on COC concentrations being above or below a range of threshold values of interest. In this analysis threshold values were chosen to represent percentiles of the COC distributions, (1, 2.5, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 95, 97.5 and 99). For each percentile, the sample data were coded as 1 for values below threshold and 0 for values above threshold, and these binary values were interpolated using natural neighbor interpolation. This process was repeated for each of the 15 threshold values, resulting in 15 interpolated surfaces representing the probability that COC concentrations were less than the threshold value. This series of 15 probability values unique to each grid cell is an estimate of the conditional cumulative distribution at that location. Traditionally this interpolation is conducted using indicator kriging. However, using natural neighbor interpolation has two distinct advantages, there is no need to

model 15 sets of directional indicator variograms necessary for kriging,, and the natural neighbor method does not require any assumptions of stationarity as is assumed for kriging. Effectively by using the natural neighbor method to interpolate the indicator data, the resulting simulation is both non-parametric as well as accommodating spatially nonstationary COC distributions.

## 13. RESULTS

---

### 13.1 DECLUSTERING METHOD SENSITIVITY

---

Estimated SWACs for PCBs based on four declustering methods ranged from 79  $\mu\text{g}/\text{kg}$  for the method stratified on RAL areas, to 205  $\mu\text{g}/\text{kg}$  based on unweighted averages within geographic strata. The geographic areas used in this analysis are presented on **Figure I-9**. The stratified method based on Thiessen Polygon weighting was 135  $\mu\text{g}/\text{kg}$ , and the method stratified based on RAL areas and using Thiessen Polygon weighting was similar to the natural neighbor method deployed in the FS. As shown, the effects of biased sampling are substantial, with higher unweighted estimates reflecting tendency to focus sampling on high concentration areas. This indicates that some form of declustering is appropriate to improve the accuracy of estimates which would otherwise be based on an unweighted average.

### 13.2 MATHEMATICAL CONSTRAINTS

---

The planned percentage SWAC reduction was plotted against percentage area remediated for PCBs to evaluate the susceptibility of remedial alternatives identified in the FS to delineation errors, and to compare with other remedial alternatives implemented at a number other Superfund Sites (**Figure I-3**). Alternatives E and G each require that the ratio of average SWAC within remediated to unremediated areas should be approximately a 10 to 1 ratio—both alternatives falling roughly along the red 10 to 1 curve. Other sites that have deployed similar ratios, include the Fox River OU4-5 and River Section 2 of the Hudson River. The results at the Fox River Site are not yet complete; however, the deposits there were relatively broadly distributed and only mildly consolidated and ultimately substantial design sampling has been required to achieve this goal. Conversely, deposits in River Section 2 of the Hudson River Site are better consolidated, but not as well consolidated as is apparent in Portland Harbor, and the desired outcome was not fully achieved there. Based on qualitative observation of the distribution of surface COCs at Portland Harbor, it is anticipated that this 10 to 1 ratio is likely to be achievable with substantially less resolution than was required at the Fox River Site, and potentially similar sampling densities to those deployed at the Hudson River in River Section 2. The conditional simulation will help to test this observation more rigorously.

### 13.3 CONDITIONAL SIMULATION

---

Conditional simulation was used to estimate uncertainty in the SWAC vs RAL relationship. The RAL was varied for each COC representing remedial action limits associated with alternatives B through G described in the FS (**Table I-2**). The lateral footprint for each RAL was defined by all grid cells with natural neighbor interpolated concentrations exceeding each specified RAL.

To simulate remediation, remediated cells were replaced with expected background concentrations and SWAC was calculated by averaging all cells (remediated and unremediated) in the map

Four equally likely simulated maps of PCB concentration are shown in **Figure I-4** to illustrate the level of variation that may occur between maps, but that is nonetheless consistent with the sample data. The RAL boundaries for Alternative E, established from the smooth natural neighbor interpolation, are overlaid so that it can be seen that for some maps, areas outside the remedial footprint exceed the 200  $\mu\text{g}/\text{kg}$  threshold and that in some areas for some maps concentrations inside the remedial footprint may be less than the RAL. Generally areas within the RAL footprints tend to be similar among all four maps; however, some areas outside the footprint tend to vary substantially, as indicated by the callouts in the left two panels. This reflects the greater sampling density within the deposits relative to somewhat lower sampling density within the navigation channel, where concentrations are lower and inaccuracies in delineation have less effect on remedial effectiveness.

Conditionally simulated SWACs for PCB concentrations varied from approximately 67 to 95 with an average of 79 prior to remediation, which was equal to the SWAC estimated from the average of the natural neighbor surface (**Figure I-5**). These values were equal because the simulation algorithm is intentionally constrained so that the synthetic mean is required to match the declustered SWAC based directly on sample data.

This range is also portrayed on **Figure I-6**, depicted as a gray band surrounding the pre-remedial SWAC estimate. The simulated SWAC distribution, depicted as red squares with error bars shows that as expected SWAC declines with lower RALs. Additionally, the uncertainty bounds on SWAC is narrower for lower RAL values reflecting that a larger remedial footprint both reduces the SWAC but also its uncertainty. Action limits of 750  $\mu\text{g}/\text{kg}$  and 1,000  $\mu\text{g}/\text{kg}$  had higher uncertainties, with remedial benefit potentially within the margin of error, as indicated by the overlapping uncertainty bounds with the pre-remedial SWAC. Post remedial SWAC for total PCB is clearly outside the margin of error of pre-remedial SWAC indicating clear expectations that the predicted remedial benefit is likely to be achieved in practice.

Pre and post remedial total PAH and DDX concentrations in relation to action limits are plotted on **Figure I-7** and **Figure I-8** respectively. These distributions are characterized by similar qualitative patterns to those observed for PCBs. Relative error is generally greater for these COCs than for PCBs which had greater skewedness in the PAH and DDX distributions, relative to the PCB distribution. Notably, the effects of this uncertainty are minimized in the post remedial forecasts where these areas are remediated under any RAL considered, and therefore their influence is eliminated from the analysis. These RAL and corresponding SWAC values are also summarized in **Table I-3**.

## 14. DISCUSSION

---

Surface weighted average concentration is an estimate exposure to receptors which may range over large areas. If sampling were purely unbiased, standard estimation methods for the mean and its confidence interval would be appropriate and less computationally complex. Because the sample data are right skewed, nonparametric, as opposed to normal theory, methods are preferred irrespective of the sampling design. If the sampling design had been unbiased, one could select one of the bootstrap based methods provided in ProUCL for estimating the mean and its UCL. However, with biased sampling prevalent at Portland Harbor it is necessary to spatially weight the data in order to reduce bias in the estimated mean and to properly characterize uncertainty bounds. Conditional simulation, is a variant of bootstrapping for designed to accommodate biased sampling designs and data that are spatially correlated.

The gray band on **Figures I-6 through I-8** represents the 95 percent confidence interval for the pre-remedial SWAC, and the error bars represent 95 percent prediction intervals for the post remedial SWAC corresponding to each RAL. When these intervals do not overlap, one can be more than 95 percent confident that the pre and post remedial means would differ ( $p < 0.05$ ). When one error bar overlaps the mean there is no difference at the 5 percent level of confidence ( $p > 0.05$ ) and when error bars overlap slightly, one can conclude that there are differences but that the confidence level may be somewhat less than 95 percent. Generally, any RAL which results in an estimated SWAC with error bars that do not overlap the confidence limits of the pre-remedial SWAC can be expected to reliably result in reduced post-remedial concentrations within the range of values bounded by the confidence limits.

It should also be noted that as the RAL declines, the error bars also decline. This is because the variance the change in SWAC is proportional to the square of the proportion of area remediated.

$$var(\Delta SWAC) = (Proportion Remediated)^2 \times var(\Delta Concentration)$$

Simply, as the size of the remedial footprint grows, the chance of making delineation mistakes declines with the area remediated. If the entire site is remediated, there is no uncertainty.
