# **PART 3 – RESPONSIVENESS SUMMARY**

## **Record of Decision**

### **Portland Harbor Superfund Site**

United States Environmental Protection Agency  
Region 10

# Table of Contents

<b>Section 1 Introduction .....</b>	<b>1-1</b>
1.1 Overview and Background .....	1-1
1.2 Community Involvement Activities before Issuing the Proposed Plan .....	1-2
1.3 Community Involvement Activities after Issuing the Proposed Plan.....	1-3
1.4 Overview of Comments Received .....	1-4
Businesses and PRPs.....	1-5
<b>Section 2 Public Comments and Responses.....</b>	<b>2-1</b>
2.1 Extent of Cleanup.....	2-1
2.1.1 Support for More Cleanup (No Specific Alternative Given).....	2-1
2.1.2 Support for Less Cleanup .....	2-3
2.2 Community and Local Business Concerns .....	2-5
2.2.1 Retain Local Jobs and Industry.....	2-5
2.2.2 Hire Locally .....	2-8
2.2.3 Move Quickly and Don't Delay Cleanup.....	2-9
2.2.4 Cleanup Will Take Too Long.....	2-10
2.2.5 The Community Needs Accurate Cleanup Costs.....	2-12
2.2.6 Cleanup Will Create Economic Impacts for Local Businesses .....	2-13
2.2.7 Cleanup Will Cause Local Taxes and Utility Rates to Rise .....	2-15
2.2.8 Implement the Cleanup Safely .....	2-17
2.2.9 Improve Opportunities for Public River Use.....	2-18
2.2.10 Address Concerns of Sauvie Island Residents .....	2-19
2.2.11 Address Enforcement Concerns.....	2-20
2.3 ARARs, PRGs, and COCs.....	2-21
2.3.1 Applicable or Relevant and Appropriate Requirements Issues.....	2-21
2.3.2 Make Unlimited Fish Consumption for All Groups a Cleanup Level and RAO.....	2-27
2.3.3 Acknowledge that Safe Fish Consumption at All Levels Is Not Supportable .....	2-29
2.3.4 Don't Select PRGs that Are Unattainable.....	2-30
2.3.5 Address PRG Issues with Risk Management or Risk Assessment.....	2-32
2.3.6 Develop Technically Sound PRGs for cPAHs in Sediment .....	2-34
2.3.7 Establish Fish Tissue Targets.....	2-35
2.3.8 Address Issues with the PRG for TPH Diesel for RAO 8 .....	2-35
2.3.9 Explain the Bis(2-Ethylhexyl) Phthalate PRG.....	2-37
2.3.10 Address Miscellaneous PRG Issues.....	2-37
2.3.11 BEHP Should Not Be a COC.....	2-39
2.4 Surface Water .....	2-40
2.4.1 Address Feasibility Study Errors Related to Surface Water.....	2-40
2.4.2 Compliance with State and Federal Standards.....	2-42
2.4.3 Address Issues with Assignment of MCLs .....	2-44
2.5 Principal Threat Waste .....	2-45
2.5.1 EPA's Identification of PTW that Cannot be Reliably Contained is Flawed.....	2-45
2.5.2 Provide Justification for PTW for Total PAHs.....	2-46
2.5.3 Reliance on Remedial Investigation Mechanistic Food Web Model Is Inappropriate ..	2-46
2.5.4 Address Miscellaneous PTW comments .....	2-47
2.6 Remedial Action Levels.....	2-48
2.6.1 Address Concerns with Establishment and Application of RALs.....	2-48

2.7 Remedial Action Objectives .....2-50

    2.7.1 Implement Changes to Remedial Action Objectives .....2-50

    2.7.2 Incorporate Newer Data in Surface Weighted Average Calculations .....2-51

    2.7.3 Address SWAC Reductions and Natural Recovery .....2-51

    2.7.4 Revisit Post-Construction SWAC Calculations .....2-53

    2.7.5 Address Inconsistencies between SWACs and Baseline Risk Assessments .....2-54

    2.7.6 Effect of Initial Condition SWAC on Chosen Alternative.....2-54

    2.7.7 Address Concerns Regarding SWAC Calculations .....2-56

2.8 Habitat.....2-61

    2.8.1 Prevent and/or Mitigate Loss of Habitat .....2-61

    2.8.2 Revegetate to Promote Habitat.....2-64

    2.8.3 Ensure Caps Do Not Reduce Habitat through Flood Rise.....2-66

    2.8.4 Consider Habitat Restoration .....2-67

2.9 Alternative Evaluation .....2-69

    2.9.1 Explain Deficiencies in the Alternative Evaluation Process.....2-69

2.10 Data Issues.....2-73

    2.10.1 Use Newer Data to Design the Remedy .....2-73

    2.10.2 Evaluate Potential Changes Raised by New Data .....2-75

    2.10.3 Explain Use of Non-Detects.....2-77

2.11 Modeling Issues.....2-77

    2.11.1 Explain Why the Mechanistic Food Web Model Is Appropriate.....2-77

2.12 Conceptual Site Model .....2-80

    2.12.1 Conceptual Site Model Does Not Adequately Characterize the Site.....2-80

    2.12.2 The CSM Does Not Properly Consider MNR .....2-82

2.13 Cleanup Technologies – Capping and Dredging.....2-83

    2.13.1 Capping Is Not an Appropriate Technology .....2-83

    2.13.2 Dredging Should Be Minimized.....2-85

    2.13.3 Use of Sheet Piles for Containment Was Not Properly Evaluated .....2-87

2.14 Cleanup Technologies - Disposal .....2-89

    2.14.1 Do Not Use a Confined Disposal Facility .....2-89

    2.14.2 Develop a Commercially-Viable Sediment and Soil Disposal Facility .....2-91

    2.14.3 Revisit the Waste Disposal Designation for Sediment Adjacent to Arkema .....2-91

    2.14.4 Explain the Cost Assumption for Treatment of PTW Near Arkema.....2-91

    2.14.5 Use the Hazardous Waste Identification Rule Appropriately.....2-91

    2.14.6 Be Aware of Additional Waste Management Needs.....2-92

    2.14.7 The ROD Should Allow for Ex-Situ Characterization of Waste.....2-92

    2.14.8 Clarify Uncertainties for Assumptions on Ex-Situ Treatment and Transloading .....2-93

2.15 Innovative and Sustainable Technologies .....2-93

    2.15.1 Evaluate Emerging Technologies throughout the Process .....2-93

    2.15.2 Consider Suggestions for Alternate Established Technologies or Products .....2-96

    2.15.3 Incorporate Relevant Sustainability Studies and Guidelines.....2-96

2.16 Monitored Natural Recovery .....2-98

    2.16.1 The Proposed Plan Relies Too Heavily on MNR .....2-98

    2.16.2 Consider Impacts on the Columbia River from Use of MNR.....2-101

    2.16.3 MNR Mechanisms and Performance Are Not Understood.....2-102

2.17 Monitoring and Contingency Actions .....2-104

    2.17.1 Provide Timelines and Metrics for Success .....2-104

    2.17.2 Ensure Fish Tissue Monitoring Is Conducted .....2-106

    2.17.3 Ensure In-River Monitoring Before, During, and After Remediation.....2-107

    2.17.4 Require Quality of Life Monitoring throughout Remediation .....2-109

2.17.5 Ensure Costs for Monitoring in Perpetuity Are Included .....2-110

2.17.6 Address Issues with Site-Specific Background .....2-111

2.18 Overall Protection of Human Health and the Environment .....2-114

    2.18.1 The Preferred Alternative is Too Protective.....2-114

    2.18.2 The Preferred Alternative is Not Protective Enough .....2-116

2.19 Long-term Effectiveness and Permanence .....2-116

    2.19.1 Long-term Effectiveness Was Not Properly Evaluated.....2-116

    2.19.2 Risk Management Was Not Properly Considered .....2-119

    2.19.3 The Exposure Scenarios Are Too Conservative .....2-123

    2.19.4 Risk Evaluation Is Inconsistent with Risk Assessment.....2-126

    2.19.5 Evaluation of Dioxins and Furans Is Inconsistent with Risk Assessment .....2-127

    2.19.6 Evaluation of Risk Should Consider Specific Factors.....2-128

    2.19.7 Alternative I Fails to Meet Several Superfund Criteria .....2-129

    2.19.8 Address Miscellaneous Risk Issues.....2-130

    2.19.9 Address Seismic Issues.....2-132

    2.19.10 Design for Climate Change .....2-134

    2.19.11 Manage Flood Rise.....2-135

2.20 Short-term Effectiveness .....2-136

    2.20.1 Address Inadequate Evaluation of Short-Term Effectiveness .....2-136

    2.20.2 Consider Externalities in Designing a Remedy .....2-140

    2.20.3 Explain Preference for Alternative I in Terms of Increased Fish Meals .....2-141

2.21 Implementability .....2-142

    2.21.1 Consider Geotechnical Issues in Dredging Adjacent to Improved Shorelines .....2-142

    2.21.2 Be Flexible in Technology Selection and Implementation .....2-142

    2.21.3 Explain Design Considerations Near and Adjacent to Navigation Channel .....2-143

    2.21.4 Identify and Stage Realistic Sediment Transload and Treatment Facilities .....2-144

    2.21.5 Consider Parameters Associated with Treating Large Volumes of Contaminated  
Sediment .....2-145

    2.21.6 Consider Implementability in Terms of Community Acceptance of Short-Term Impacts  
.....2-145

    2.21.7 Ensure Free Passage of Ship Traffic during Remediation.....2-146

    2.21.8 Ensure Remediation Time Frames Are Realistic .....2-146

    2.21.9 Ensure Cleanup Does Not Impact Site Features .....2-150

2.22 Cost .....2-151

    2.22.1 Perform a Cost Effectiveness Analysis .....2-151

    2.22.2 Provide Costs by SDU .....2-152

    2.22.3 Provide Detail and Backup For Estimated Costs of Each Alternative.....2-152

    2.22.4 Improve Accuracy of Production Rates, Durations, and Schedule.....2-153

    2.22.5 Modify Contingency Percentages .....2-155

    2.22.6 Revisit Costs for Water Quality Control Structures.....2-157

    2.22.7 Provide Details on Dredging Equipment, Sediment Handling and Disposal, and  
Implementability .....2-158

    2.22.8 Provide Dredge Volume and Cap Overplacement Costs.....2-160

    2.22.9 Explain Mobilization and Demobilization Costs .....2-160

    2.22.10 Explain Indirect Costs .....2-161

    2.22.11 Include Department of State Lands Fees .....2-162

    2.22.12 Explain the Selection of the Discount Rate .....2-163

    2.22.13 Be Flexible in Technology Assignment, Current Conditions, and Site Factors Affecting  
Cost Estimates .....2-163

    2.22.14 Ensure Availability of Suitable Capping Material .....2-164

2.22.15 Modify Transloading Costs.....	2-165
2.23 Paying for Cleanup .....	2-165
2.23.1 Ensure the PRPs Pay For Cleanup.....	2-165
2.23.2 Require Performance Bonding.....	2-167
2.24 Flexibility in Implementing Cleanup.....	2-168
2.24.1 Address the Most Contaminated Areas First .....	2-168
2.24.2 Consider Assorted Flexibility Requests.....	2-170
2.25 Early Action Sites.....	2-171
2.25.1 Coordinate Cleanup with Work at Early Action Sites.....	2-171
2.26 Clean Up of Specific Areas of the Waterway .....	2-174
2.26.1 Address Outstanding Issues Sediment Management Areas .....	2-174
2.26.2 Correct Contaminant Characterization of the River Banks .....	2-176
2.26.3 Clearly Identify the River Bank Remedy.....	2-178
2.26.4 Address River Bank PRG or RAO Comments.....	2-180
2.26.5 Explain Property-Specific Technology Assignments.....	2-181
2.26.6 Consider Site Factors that May Impact Implementation .....	2-182
2.26.7 Explain Technology Assignments for Shallow and Nearshore Areas .....	2-183
2.26.8 Consider Maintenance Dredging Effects on Technology Assignments .....	2-184
2.26.9 Better Define Habitat Mitigation Requirements.....	2-184
2.26.10 Provide Technology Assignment Flexibility .....	2-184
2.26.11 Clarify the Decision Matrix.....	2-185
2.26.12 Improve Technology Assignment Flow Charts .....	2-186
2.27 Source Control and Sediment Recontamination.....	2-187
2.27.1 Ensure Source Areas Are Controlled .....	2-187
2.28 ICs.....	2-190
2.28.1 Develop a Plan for Implementing ICs .....	2-190
2.28.2 Incorporate Education of the Public into Fish Consumption Advisories .....	2-192
2.28.3 Reduce Use of ICs in General and Monitor Carefully .....	2-194
2.29 Remedy Compatibility with Current and Future Use .....	2-196
2.29.1 Prevent Conflict with USACE Dredging .....	2-196
2.29.2 Prevent Conflict with City’s Comprehensive Land Use Planning .....	2-198
2.30 Miscellaneous Regulatory and Legal Issues.....	2-199
2.30.1 Be Consistent in Treatment of PRPs .....	2-199
2.30.2 Explain Why Standard Procedures Appear to Be Misapplied .....	2-200
2.30.3 Explain Why LWG’s Feasibility Study Was Not Sufficient.....	2-201
2.30.4 Consider that Flaws in the Proposed Plan Will Encourage Litigation .....	2-201
2.30.5 Respond Fully to Freedom of Information Act Requests.....	2-201
2.31 Support for Another Alternative.....	2-202
2.31.1 Consider Community Support for Alternatives B, E, G, G+, or H .....	2-202
2.31.2 Evaluate a Different Alternative for Swan Island.....	2-205
2.32 Proposed Plan Content.....	2-206
2.32.1 Provide Capital Costs that Are Lacking in the Proposed Plan .....	2-206
2.32.2 Address McCormick and Baxter Superfund Site Issues.....	2-207
2.32.3 Explain the Depiction of Groundwater Plumes in Proposed Plan .....	2-208
2.32.4 Address the Groundwater Transport Mechanism .....	2-208
2.32.5 Provide Information Lacking on Dioxin/Furan Data .....	2-209
2.32.6 Explain Why Mercury is Not Included in the Description of Risk Reduction .....	2-209
2.32.7 Explain Why PTW Figures Are Different .....	2-210
2.32.8 Provide Studies of Technology Use at Other Superfund Sites .....	2-210

2.33 Human Health Risk.....2-211

    2.33.1 Evaluate Existing Exposure From PCBs in Air .....2-211

    2.33.2 Include Transient Species in Risk Evaluation .....2-213

2.34 Ecological Risk.....2-214

    2.34.1 Address Inconsistencies in Benthic Risk .....2-214

2.35 Environmental Justice.....2-218

    2.35.1 Eliminate the CDF .....2-218

    2.35.2 Improve Insufficient Outreach to Environmental Justice Communities .....2-219

    2.35.3 Consider Food-Based Environmental Justice Issues.....2-224

    2.35.4 Consider Specific Suggestions for Additional Environmental Justice Support .....2-226

    2.35.5 Address Issues of Financial Support Related to Environmental Justice .....2-228

    2.35.6 Support Job Creation in Impacted Communities .....2-229

    2.35.7 Address Environmental Justice in Regards to Relocation Housing.....2-231

2.36 Public Participation.....2-232

    2.36.1 Address Public Outreach Related to the Proposed Plan or Earlier .....2-232

    2.36.2 Improve Public Outreach After the ROD Is Signed .....2-234

    2.36.3 Be Transparent in Decision Making .....2-236

2.37 Agency Roles and Cooperation .....2-237

    2.37.1 Require Federal Oversight of Cleanup .....2-237

    2.37.2 Require DEQ Oversight of Groundwater Cleanup and Other Issues.....2-239

    2.37.3 Retain DEQ as the Lead Agency for River Bank Source Control .....2-241

    2.37.4 Ensure Interagency Coordination .....2-242

2.38 Tribal Comments Received From the Public .....2-244

    2.38.1 Ensure Consultation and A Role in the Process .....2-244

    2.38.2 Respect Treaty Obligations with the Yakama and Others .....2-245

**Section 3 Tribal Comments and Responses..... 3-1**

3.1 Five Tribes .....3-1

    3.1.1 Require a Protective, Aggressive, and Large-Scale Remedy.....3-1

    3.1.2 Establish a Timeframe in Which to Meet RAOs.....3-2

    3.1.3 Use MNR and ENR Judiciously .....3-2

    3.1.4 Recognize Issues with Capping .....3-3

    3.1.5 Explain Long-Term Management of Sediment Caps .....3-3

    3.1.6 Do Not Let Convenience and Cost Savings Bias Use of Caps .....3-3

    3.1.7 Limit the Need for ICs .....3-4

    3.1.8 Do Not Leave PTW that Cannot Be Reliably Contained .....3-4

    3.1.9 Do Not Increase PRG Values in the ROD.....3-4

    3.1.10 Do Not Issue ARAR Waivers.....3-5

    3.1.11 Address Community Concerns Through BMPs and Monitoring.....3-5

    3.1.12 Select a Version of Alternative G.....3-5

    3.1.13 Use PRGs as Cleanup Levels in ROD .....3-6

    3.1.14 Retain EPA’s Definition of PTW for the Site.....3-6

    3.1.15 Include River Banks in Remedy.....3-7

    3.1.16 Use BHRRA Fish Consumption Rates .....3-7

    3.1.17 Reject LWG’s Hydrodynamic and Sediment Transport Model .....3-7

    3.1.18 Use the Current Portland Harbor Dataset .....3-7

    3.1.19 Reject Alternatives B and D as They Are Not Sufficiently Protective .....3-8

    3.1.20 Use BMPs as Needed.....3-8

    3.1.21 Use A Cover Layer to Control Residuals After Dredging .....3-8

    3.1.22 Explain How Alternative I Meets the Protectiveness Criterion.....3-8

3.1.23 Explain Why Alternative G Was Rejected as It Is the Only Alternative to Meet ARARs 3-9

3.1.24 Defer to the Most Environmentally Protective Alternative ..... 3-9

3.1.25 Let Long-Term Protection Drive the Decision Process ..... 3-10

3.1.26 Consider Alternative G Which Meets the Protection Goal in 10 Years ..... 3-10

3.1.27 Do Not Choose a Middle Ground Remedy by Default ..... 3-11

3.1.28 Rescore the Short-Term Effectiveness Criterion ..... 3-11

3.1.29 Give Less Weight to Benthic Impacts During Construction ..... 3-12

3.1.30 Consider Alternative F or G Based on Greater Risk Reduction ..... 3-12

3.1.31 Address Issues with Presentation of NAPL and PTW Areas ..... 3-13

3.1.32 Expand SMAs ..... 3-13

3.1.33 Limit Use of MNR – Especially in RM 6NAV SDU ..... 3-14

3.1.34 Select Removal Over Capping where Feasible ..... 3-15

3.1.35 Explore Removing Wharfs and Shore-Based Facilities ..... 3-15

3.1.36 Address Other Relevant Cap Types for PTW Remediation ..... 3-16

3.1.37 Use a Biologically Active Zone of 8 Rather than 4 Inches ..... 3-16

3.1.38 Consider Sandy Material with Higher Organic Content ..... 3-17

3.1.39 Address Concerns with Thin Layer Placement ..... 3-17

3.1.40 Explain USACE Role in Dredging at the Site ..... 3-18

3.1.41 Consider All Aspects of Using a CDF ..... 3-19

3.1.42 Enact Protective Advisories Quickly ..... 3-20

3.1.43 Reduce Contaminant Inputs to the Site ..... 3-20

3.1.44 Clarify Authority for Fish Consumption Advisories ..... 3-21

3.1.45 Ensure Fish Consumption Advisories Are Protective of All Groups ..... 3-21

3.1.46 Set Post-Cleanup Fish Consumption Advisories Using Pre-Cleanup Methods ..... 3-21

3.1.47 Consider Migratory Fish Consumption Restrictions ..... 3-21

3.1.48 Provide Assumptions for Use of Fish Consumption Advisories ..... 3-22

3.1.49 Revisit Strategies for Fish Consumption Advisory Signage ..... 3-22

3.1.50 Get Input on Whether ICs in Regulated Navigation Areas Will Be Burdensome ..... 3-22

3.1.51 Develop an ICs Implementation and Assurance Plan ..... 3-23

3.1.52 Specify Frequency of Monitoring to Ensure ICs Are Effective ..... 3-23

3.1.53 Ensure Flexibility in Implementation of Remedy ..... 3-23

3.1.54 Be Flexible in Remedy Implementation ..... 3-24

3.1.55 Engage MOU Partners in Evaluating Sampling Plans ..... 3-25

3.1.56 Reevaluate Deposition Scoring ..... 3-25

3.1.57 Modify Deposition Area Scoring ..... 3-25

3.1.58 Change Preference for Capping When Scores Are Equal to Dredging ..... 3-25

3.1.59 Reconsider Applicability of Capping in Troublesome Areas ..... 3-26

3.1.60 Address Inconsistencies in Technology Assignment Flowcharts ..... 3-26

3.1.61 Use Capping Consistent Nomenclature ..... 3-27

3.1.62 Remove as Much PTW and NAPL as Possible ..... 3-27

3.1.63 Apply Higher Standard for Deciding to Leave a Structure in Place ..... 3-27

3.1.64 Address Lateral Migration under Caps ..... 3-27

3.1.65 Minimize Capping in Shallow Areas where Possible ..... 3-28

3.1.66 Address Intermediate Area Issues with Flowchart ..... 3-28

3.1.67 Incorporate the Same Decision Rule for Shallow Areas as Intermediate Areas ..... 3-28

3.1.68 Clarify Procedure if NAPL or NRC PTW Is Found at Depth ..... 3-29

3.1.69 Revisit Background Levels as Cleanup Progresses ..... 3-29

3.1.70 Explore Additional Options for Upgradient Sites ..... 3-29

3.1.71 Address River Bank Active Remediation Questions ..... 3-30

3.1.72 Remediate a Higher Percentage of the Groundwater Plume ..... 3-30

3.1.73 Use a More Protective Remedy – Based on Benthic Risk..... 3-31

3.1.74 Address Issues with Beaches..... 3-31

3.1.75 Consider Additional Strategies in the Green Remediation Plan ..... 3-31

3.1.76 Evaluate the Feasibility of an On-Site Transloading Facility..... 3-32

3.1.77 Select a Time Period Greater than 100 Years for Evaluation..... 3-32

3.1.78 Ensure EPA’s Definition of Shallow Water Matches that Used by NMFS..... 3-33

3.1.79 Conduct a Flood Rise Evaluation Using a DMM Scenario..... 3-33

3.1.80 Determine Dredging Practices that Are the Most Protective ..... 3-33

3.1.81 Clarify Referencing of Figures 4.2-9 through 4.2-17 ..... 3-34

3.1.82 Use Enforcement Measures to Obtain PRP Compliance..... 3-34

3.1.83 Describe Decision-Making for Adaptive Management and Future Monitoring ..... 3-34

3.1.84 Identify Time-Dependent Decision Points..... 3-35

3.1.85 Clarify the Schedule for Five-Year Reviews ..... 3-35

3.1.86 Engage the Tribes throughout the Remediation Process ..... 3-35

3.1.87 Collect Additional Data Regarding Erosion and Deposition During Remediation..... 3-36

3.1.88 Incorporate Effective BMPs in Remedial Design to Reduce Fish Mortality ..... 3-37

3.2 Confederated Tribes and Bands of the Yakama Nation ..... 3-37

3.2.1 Eliminate Health Advisories as a Result of Toxic Releases..... 3-37

3.2.2 Provide More Aggressive Cleanup in Erosional Areas..... 3-38

3.2.3 Clarify the Role of the Confederated Tribes and Bands of the Yakama Nation in  
Overseeing Cleanup..... 3-38

3.2.4 Uphold the Federal Trust Responsibility..... 3-39

3.2.5 Meet Threshold Requirements for Protectiveness..... 3-40

3.2.6 Comply with ARARs..... 3-41

3.2.7 Remove all PTW ..... 3-41

3.2.8 Protect Shorelines and Nearshore Habitat ..... 3-41

3.2.9 Evaluate Upland Source Control and Provide Assurances..... 3-42

3.2.10 Include a Contingency Plan ..... 3-42

3.2.11 Honor Confederated Tribes and Bands of the Yakama Nation Treaty Rights ..... 3-42

3.2.12 Recognize Trust Responsibility ..... 3-44

3.2.13 Revisit Site Boundaries versus Study Area ..... 3-46

3.2.14 Monitor for Impacts to Species..... 3-46

3.2.15 Recognize Impacts on Endangered Species Recovery Efforts ..... 3-46

3.2.16 Follow NRRB Recommendation on Columbia River Impacts ..... 3-47

3.2.17 Follow Recommendations of the Confederated Tribes and Bands of the Yakama Nation  
..... 3-47

3.2.18 Explain Why Threshold Criteria Are Not Met ..... 3-48

3.2.19 Address Issues in Meeting Threshold Criteria..... 3-48

3.2.20 Address Issues with ARARs..... 3-48

3.2.21 Avoid Over-Reliance on ICs ..... 3-49

3.2.22 Remove All PTW ..... 3-50

3.2.23 Address Lack of a Consistent, Conservative Approach and Additional Uncertainties 3-50

3.2.24 Follow NRRB Recommendations on Risk Level Uncertainty ..... 3-52

3.2.25 Discuss Areas that Will Not Be Cleaned Up ..... 3-53

3.2.26 Address Non-Compliance with Short- and Long-Term Risk Goals..... 3-54

3.2.27 Lessen Reliance on MNR..... 3-54

3.2.28 Address Uncertainty with ENR..... 3-56

3.2.29 Mitigate Nearshore Habitat Impacts..... 3-56

3.2.30 Address Contamination at McCormick and Baxter Superfund Site..... 3-57

3.2.31 Explain Cost Estimate Inaccuracies ..... 3-57

3.2.32 Change Heavy Bias On Cost in the Remedy Decision .....	3-58
3.2.33 Provide Detail to Substantiate Remedy Selection Conclusions .....	3-59
3.2.34 Perform Key Studies .....	3-60
3.2.35 Implement NRRB Recommendation on Performance Monitoring.....	3-61
3.2.36 Provide Clear Metrics and Monitoring Goals .....	3-61
3.2.37 Provide Acceptance Criteria for Caps and Daily Cover .....	3-62
3.2.38 Specify PCB Analysis Methodology .....	3-62
3.2.39 Conduct an Environmental Justice Analysis .....	3-63
3.2.40 Use Upstream to Downstream Cleanup Sequence .....	3-63
3.2.41 Clarify Use of Waivers .....	3-63
3.2.42 Follow NRRB Recommendation to Define Recovery Timeframe.....	3-63
3.2.43 Clarify the Five-Year Review Schedule .....	3-64
3.2.44 Provide a Contingency Plan .....	3-64
3.2.45 Provide Rationale for Using RM 16 as Background .....	3-64
3.2.46 Include NRRB Recommendation for Source Control Management in ROD.....	3-65
3.2.47 Address Upland Source Control Needs.....	3-65
3.2.48 Prevent Recontamination.....	3-67
3.2.49 Develop a Regional Plan for Addressing Contaminants.....	3-67
3.2.50 Do Not Use Roosevelt Landfill .....	3-68
3.2.51 Do Not Use a CDF.....	3-69
3.3 Confederated Tribes of the Grand Ronde.....	3-69
3.3.1 Select Alternative G.....	3-69
3.3.2 Continue Engagement with Tribe to Ensure Protectiveness.....	3-69
3.3.3 Review Attached Documents Supporting Alternative G.....	3-71
3.4 Confederated Tribes of Siletz Indians .....	3-71
3.4.1 Address the Comments Submitted by the Five Tribes .....	3-71
3.5 Confederated Tribes of the Warm Springs Reservation .....	3-71
3.5.1 Select a More Aggressive Alternative.....	3-71
3.5.2 Do Not Use MNR/ENR in the Most Contaminated Areas.....	3-71
3.5.3 Use a Minimum Cap Thickness of 16 Inches Instead of 12 Inches .....	3-72
3.5.4 Clarify Plans for Addressing Groundwater.....	3-72
3.5.5 Ensure ICs are Used .....	3-72
3.5.6 Reconsider Alternative G.....	3-73
3.5.7 Ensure Any CDF Is Secure in Perpetuity.....	3-73
3.5.8 Update, Advertise, and Better Educate the Public on Fish Advisories .....	3-73
3.5.9 Commit to Engaging the Tribe throughout Remediation.....	3-74
3.5.10 Hold PRPs Accountable and Remedy Damages to Tribal Resources.....	3-74
3.6.1 Nez Perce Tribe .....	3-75
3.6.1 Let Long-Term Protection of Human Health and the Environment Drive the Remedy Decision .....	3-75
3.6.2 Select a Remedy That Meets Threshold Criteria .....	3-75
3.6.3 Do Not Focus on Short-Term Impacts.....	3-76
3.6.4 Use Conservative Estimates for Recovery and Focus on Removal .....	3-76
3.6.5 Eliminate the Need For Fish Consumption Advisories.....	3-76
<b>Section 4 Oregon Department of Environmental Quality Comments and Responses .....</b>	<b>4-1</b>
4.1 Overall Comments.....	4-1
4.1.1 Ensure Protection by Issuing a Final Decision and Initiating Cleanup Quickly.....	4-1
4.1.2 Address Environmental Justice through Early Action.....	4-3
4.1.3 Evaluate MNR Effectiveness in Detail after the ROD.....	4-4

4.1.4 Aggressively Clean Areas Posing Risk to the Benthic Community and Lamprey ..... 4-6

4.1.5 Accommodate Current and Future Uses of the Harbor ..... 4-8

4.1.6 Consider Potential Impacts of Transportation Modes..... 4-10

4.1.7 Allow Design Flexibility to Account for Uncertainty ..... 4-11

4.1.8 Realize Cleanup Costs are Uncertain and Likely Underestimated..... 4-13

4.1.9 Focus Cleanup Levels on the Sediment Remedy ..... 4-15

4.1.10 Revise River-Bank Approach to Be Consistent with Joint Source Control Strategy... 4-16

4.1.11 Consider the Different Types of Groundwater Plumes in Cleanup..... 4-17

4.1.12 Clarify Oregon Marine Board’s Authority and Role in Implementation..... 4-18

4.1.13 Recognize Department of State Lands’ Authority and Role in Implementation..... 4-19

4.1.14 Clarify Oregon Health Authority’s Role in Developing and Implementing Fish  
Advisories..... 4-21

4.2 Specific Text Concerns..... 4-23

## Appendices

Appendix A PRP Dispute Resolutions for June 2016 - Legacy Site Services, Lower Willamette Group,  
Union Pacific Railroad

## Acronyms and Abbreviations

AOC	Administrative Order on Consent
ARAR	applicable or relevant and appropriate requirements
BaPEq	benzo(a)pyrene equivalents
BEHP	bis(2-ethylhexyl) phthalate
BERA	baseline ecological risk assessment
BHHRA	baseline human health risk assessment
BMPs	best management practices
CAG	Portland Harbor Community Advisory Group
CDF	confined disposal facility
CERCLA	Comprehensive Environmental Response, Compensation & Liability Act of 1980
C-FERST	Community-Focused Exposure and Risk Screening Tool
CFR	Code of Federal Regulations
cPAH	carcinogenic polycyclic aromatic hydrocarbon
COC	contaminant of concern
CSM	conceptual site model
DDE	dichlorodiphenyldichloroethylene
DDT	dichlorodiphenyltrichloroethane
DEQ	Oregon Department of Environmental Quality
DDx	sum of 2,4'- and 4,4'- DDD; 2,4'- and 4,4'- DDE; and 2,4'- and 4,4'- DDT
EJSCREEN	EPA's environmental justice screening tool
ENR	enhanced natural recovery
EPA	U.S. Environmental Protection Agency
FMD	future maintenance dredge
HxCDF	1,2,3,4,7,8-hexachlorodibenzofuran
ICs	institutional controls
LSS	Legacy Site Services
LWG	Lower Willamette Group
MCL	maximum contaminant level
MCLG	maximum contaminant level goal
MNR	monitored natural recovery
M/W/ESB	Minority, Women and Emerging Small Business enterprises
MOU	February 2001 Memorandum of Understanding
NAPL	non-aqueous phase liquid
NAVD88	North American Vertical Datum 1988

NCP	National Contingency Plan
NMFS	National Marine Fisheries Service
NPDES	National Pollutant Discharge Elimination System
NPL	National Priorities List
NRRB	National Remedy Review Board
OU	operable unit
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PeCDD	1,2,3,7,8-pentachlorodibenzo-p-dioxin
PeCDF	2,3,4,7,8-pentachlorodibenzofuran
ppb	parts per billion
PRG	preliminary remediation goal
PRP	potentially responsible party
PTW	principal threat waste
RAL	remedial action level
RAO	remedial action objective
RM	river mile
RNA	regulated navigation area
ROD	record of decision
SDU	sediment decision unit
SEF	Sediment Evaluation Framework
Site	Portland Harbor Superfund Site
SMA	sediment management area
SuperJTI	Superfund Jobs Training Initiative
SWAC	surface-weighted average concentrations
TCDD	tetrachlorodibenzo-p-dioxin
TCDF	2,3,7,8-tetrachlorodibenzofuran
TPH	total petroleum hydrocarbon
UCLs	upper confidence limits
µg/kg	micrograms per kilogram
µg/L	micrograms per liter
USACE	U.S. Army Corps of Engineers

# Section 1

## Introduction

### 1.1 Overview and Background

This responsiveness summary provides a summary of the public's comments submitted to the U.S. Environmental Protection Agency (EPA) regarding the proposed plan (USEPA 2016c) for the in-river portion of the Portland Harbor Superfund Site (Site) and EPA's responses to those comments. A responsiveness summary is required by the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) at 40 Code of Federal Regulation (CFR) § 300.430(f)(3)(F). All comments summarized in this document have been considered in EPA's final decision for the selection of the remedy for the Site.

During the public comment period, 7 out of the 10 signatories to the *Administrative Settlement and Order on Consent for the Remedial Investigation/Feasibility Study* (AOC), U.S. EPA Docket No. CERCLA-10-2001-0240, submitted three separate formal dispute statements<sup>1</sup> regarding EPA's feasibility study report (USEPA 2016b).

EPA's responses to all of the dispute issues are included as a part of this responsiveness summary. The dispute statements and supporting information provided by the Lower Willamette Group (LWG) have been considered in EPA's final decision for the selection of the remedy for the Site. These documents, EPA's responses, and the final dispute decision by the Director of Region 10's Office of Environmental Cleanup are included in the Administrative Record, which contains this record of decision (ROD) and other documents that form the basis for EPA's selected remedy.

EPA has worked closely with tribes, community members, and other stakeholders throughout the development of the remedial investigation, feasibility study, and proposed plan for the Site. Community participation played an essential role in the development of the proposed plan and ROD for the Site and is described in more detail below.

The responsiveness summary is organized as follows:

- Section 1 – Introduction
- Section 2 – Public Comments and Responses
- Section 3 – Tribal Comments and Responses
- Section 4 – State Comments and Responses
- Section 5 – National Marine Fisheries Service (NMFS) Comments and Responses

---

<sup>1</sup> The seven LWG members are: Arkema, Inc., Chevron, U.S.A. Inc., Evraz, Inc. N.A., Gunderson LLC, NW Natural, TOC Holdings Co., and Union Pacific Railroad Company.

- Section 6 – References Cited
- Appendix A – PRP Dispute Resolutions for June 2016 – Legacy Site Services, Lower Willamette Group, Union Pacific Railroad

## 1.2 Community Involvement Activities before Issuing the Proposed Plan

EPA's outreach goal is to educate the community about the work being done at the Site and collaborate with stakeholders on how to successfully engage the public. In 2002, EPA developed a Community Involvement Plan after interviewing community members and other stakeholders. The plan has been updated throughout the process. Since the Site was listed, EPA has used public information sessions, fact sheets, websites, one-on-one discussions, and participation in community events as ways to share information about the Site with the broader community. Furthermore, EPA has provided financial support to the Willamette Riverkeeper since 2001 via a technical assistance grant, which allows a community group to contract their own technical advisor to interpret and explain technical reports, site conditions and EPA's proposed cleanup proposals and decisions. The Willamette Riverkeeper has used this grant to give support to the Portland Harbor Community Advisory Group (CAG), which provides a public forum for community members to learn about the Site and share community needs and concerns. Additionally, EPA established a listserv for the Site that now has over 3,000 subscribers as a method for sharing information and relevant events quickly and efficiently.

EPA made significant community outreach efforts leading up to the release of the proposed plan (USEPA 2016c) to get community input and to prepare people to participate in the public comment period. These efforts included producing and disseminating quality information such as community information cards, fact sheets, and videos; establishing information repositories at the Multnomah County Central Library, the St. Johns Library and the Kenton Library where the public can review documents associated with the Site; maintaining current information on EPA's Portland Harbor website; providing valuable information via the EPA Portland Harbor listserv; sustaining strong partnerships with the Oregon Department of Environmental Quality, the Oregon Health Authority, and the City of Portland to maximize community outreach efforts; attending and presenting at public forums and meetings; and organizing multiple community information sessions during January, February, and March of 2016. A detailed list of specific community involvement activities is available in EPA's current Portland Harbor Community Involvement Plan (accessible on EPA's website).

Additionally, EPA has engaged with many different groups over the years, including groups that represent or are concerned about communities with environmental justice concerns. EPA takes environmental justice seriously and has worked to understand environmental justice concerns in the Portland Harbor study area by using existing tools (such as EPA's Environmental Justice Screen tool and Community-Focused Exposure and Risk Screening Tool), applying the six principles of environmental justice that are outlined in Executive Order 12898 (Environmental Justice: Guidance Under the National Environmental Policy Act) and working with community groups. Some of the main groups that EPA has engaged with at the Portland Harbor Superfund Site include Communities of Color, Native American Youth Association, Latino Network, Right 2 Dream Too, Right 2 Survive, Willamette Riverkeeper, the Slavic Immigrant Association, Ecumenical Ministries Oregon, the Coalition of Black Men, the Oregon Environmental Justice Task Force, Oregon Tradeswomen, League of Women Voters, Verde, Portland Harbor Community Coalition, Sierra Club Portland, Occupy St.

Johns, Audubon Society, Asian Pacific American Network of Oregon, Vietnamese Community of Oregon, Portland neighborhood associations, and schools. EPA will continue to work with these groups and other interested parties to make sure that future outreach efforts reach historically underrepresented communities.

Lastly, throughout the process, EPA has meaningfully engaged with the affected tribes (the Confederated Tribes and Bands of the Yakama Nation, the Confederated Tribes of the Grand Ronde Community of Oregon, the Confederated Tribes of Siletz Indians, the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes of the Warm Springs Reservation of Oregon, and the Nez Perce Tribe) and has encouraged and facilitated tribal involvement, including conducting formal tribal consultations. The tribes were active members of the Technical and Legal Coordinating Teams for the Site established under a Memorandum of Understanding signed in 2001. The most recent government-to-government consultations occurred in July 2016. EPA considered numerous factors, such as tribal fish consumption rates and the effects of contamination at the Site on treaty-protected resources, to develop remedial alternatives for the Site. EPA recognizes that these tribes have treaty-reserved or other fishing rights in areas impacted by the Site and that, once implemented, the cleanup will improve fish habitat and help further the tribes' rights to fish.

Public outreach activities are further described in response to specific comments in Sections 2.35.2 and 2.36.1 of this document.

## 1.3 Community Involvement Activities after Issuing the Proposed Plan

Specific public engagement activities and other activities were conducted just prior to and after the June 8, 2016 release of EPA's Superfund proposed plan (USEPA 2016c) for the cleanup of the in-river portion of the Site. EPA extended the public comment to 90 days from the 30 days required by the NCP due to high community interest and requests for extensions. The public comment period ran from June 9 to September 6, 2016. The remedial investigation, feasibility study, proposed plan, and maps and other supporting documents were posted on EPA's Portland Harbor webpage. Hard copies and compact discs of the proposed plan and administrative record were made available at the information repositories.

The public comment period was announced in a number of locations to reach the widest audience possible. A public notice appeared in *The Oregonian* (both print and online) on June 8, 2016. Additionally, EPA sent announcements to the EPA Portland Harbor e-mail listserv, the Portland Office of Neighborhood Involvement e-mail list and the Portland Harbor CAG; posted to the EPA Region 10 Facebook page and Twitter page; delivered information to media outlets; and also updated the EPA Portland Harbor website.

EPA held a series of four public meetings during the public comment period. These public meetings were well advertised via e-mail, posting on the Portland Harbor website and on EPA social media accounts, dissemination of media advisories, and directly posting EPA notices in *The Oregonian*, *The Skanner*, *The Asian Reporter*, *El Hispanic News* (translated into Spanish), *KAHOH* (translated into Russian), and the *Phường Đông Times* (translated into Vietnamese). The meeting venues were widely spaced throughout the metro area (City of Portland Building, EXPO Center, University Place Conference Center, and the Ambridge Center). Two formal presentations of the plan were given at each meeting, followed by a question and answer period and an informal open house where the public could discuss the plan directly with EPA staff and ask questions one-on-one. At all public meetings,

there were opportunities to provide both written and oral comments on the proposed plan for the record. Language interpreters were available in person at the June 24 meeting (Spanish, Russian, Vietnamese, and Chinese) and at the July 20 meeting in the evening (Spanish, Russian and Arabic) and by telephone if needed for the June 29 and July 11 meetings. A community fact sheet as well as an acronym, glossary, contaminant summary and a handout detailing how to give written or oral comments were available in English, Spanish, Vietnamese, Chinese, and Russian at each public meeting. Transcripts from all of the public meetings are in the Administrative Record.

In addition to EPA-sponsored public meetings during the proposed plan public comment period, EPA discussed the proposed plan with the Confederated Tribes of Warm Springs, the Confederated Tribes of Grand Ronde, the Yakama Nation, Confederated Tribes of the Umatilla Indian Reservation and the Nez Perce Tribe, the potentially responsible parties (PRPs) allocation group, the Portland City Council and the Federal Congressional Delegation

Public outreach activities are further described in response to specific comments in Sections 2.35.2 and 2.36.1 of this document.

EPA's efforts to provide opportunities for public participation have gone well beyond the requirements of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and the NCP. The input EPA received from the public and other stakeholders throughout the remedial investigation/feasibility study was instrumental in developing the proposed plan and the ROD. Changes to the selected remedy as a result of public comment are documented in the ROD and in responses to comments in this responsiveness summary. The ongoing involvement of the community, tribes, and other stakeholders will remain an important part of the cleanup as it moves forward.

## 1.4 Overview of Comments Received

A total of 5,348 individual comment submissions were received. Comments were received by mail (paper post cards and letters), email, submission of written comments at public meetings, and submission of oral comment at public meetings (stenographer's transcript). Many comments were clearly personal thoughts (typed or hand written) and others were "form" submissions that were part of mailing or email campaigns, often with personal comments added. Any comments that were received in another language (oral or written) were translated.

Each submission was given a sequential individual comment ID number. Some commenters submitted more than once in the comment period using one or more of several different methods. For each ID number assigned, basic identification information (date received, commenter name, comment method [e.g., email, letter, and transcript], title or opening sentence) were tracked. A master spreadsheet was developed to track assigned identification numbers (such as 101.1, 101.2, 101.3, etc.) and the comments made in each submission. For larger comment submissions (generally from PRPs, government entities, or organizations), a summary of the comment was entered in the master spreadsheet. Names of individuals who submitted comments were recorded and tracked but are not available to the public due to EPA's Privacy Policy and commitment to protect personally identifiable information. Names of businesses, organizations, and government entities submitting comments are listed in Exhibit 1 below.

---	---	---

A majority of comments received by EPA showed support for a cleanup of the river. Opinions on how that cleanup should take place were more diverse. A large number of commenters want more cleanup to occur than what was proposed while some commenters believe less active cleanup is needed. The most commonly seen comments were those that were included in form mailings (email or standard mail). The top 10 comments are shown below along with the section number in this responsiveness summary in which they are addressed in this document (from most to least common):

1. Clean up should make unlimited fish consumption safe for all groups of people (Section 2.3.2)
2. Support for more cleanup than Alternative I (Section 2.1.1)
3. Do not use a confined disposal facility (Section 2.14.1)
4. Consider community support for another cleanup alternative (B, G, G+, and/or H) (Section 2.31.1)
5. Ensure that the PRPs pay for cleanup (Section 2.23.1)
6. Ensure source areas are controlled (Section 2.27.1)
7. Improve insufficient environmental justice response (Section 2.35.2)
8. Provide timelines and metrics for success (Section 17.1)
9. Ensure instream monitoring before, during, and after remediation (Section 2.17.3)
10. Move quickly and don't delay cleanup (Section 2.2.3)

From a very big picture perspective, the CAG supported more cleanup than the preferred alternative and opposed use of a confined disposal facility (CDF). Environmental and/or community organizations generally echoed the CAG's concerns and wanted quality of life monitoring during cleanup and better baseline monitoring. They also wanted to make sure that the PRPs would be held responsible for the cost of cleanup. The tribes wanted more cleanup and were generally concerned with human health risk from ingestion of fish, environmental risk, the role of the tribes in remedial design and cleanup, and the protection of treaty rights. Groups representing businesses and those PRPs that submitted comments generally opposed all or large components of the preferred alternative, based on cost, cost-effectiveness, and technical concerns. They wanted flexibility in implementing the remedy (where and how) and also wanted remedial action levels to be more consistent throughout the Site. Local government comments cited jobs, infrastructure, cost, short-term impacts, sustainability, seismic and climate change issues, and coordination with EPA and the state. The state was supportive of the preferred alternative and provided comments that, among other things, asked for more flexibility during remedy implementation, requested more detail about river bank cleanup, and identified the need for the remedy to be coordinated with Department of State Lands, where necessary. Most people who expressed a preference in the remedy cited Alternatives G or H. Some local residents expressed concern over the cost of the preferred alternative, impacts on jobs and the local economy from the cleanup, and construction impacts of any remediation.

EPA received a number of submissions days and months after the close of the comment period. The comments have been labeled as "late comments" and added to the administrative record file. EPA has reviewed the late comments, including the documents enclosed with them. Consistent with 40 CFR § 300.825(c), the comments are included in the administrative record file as late comments, as opposed to being incorporated into the responsiveness summary, because none of the comments, or other information submitted with the comments, substantially support the need to significantly alter EPA's selected remedy. Moreover, much of the information is somewhat or entirely duplicative of information already contained in the administrative record file.

## Section 2

# Public Comments and Responses

## 2.1 Extent of Cleanup

### 2.1.1 Support for More Cleanup (No Specific Alternative Given)

#### Comment Summary

A total of 2,437 comments expressed support for a more robust cleanup than what was described in the proposed plan (USEPA 2016c). About half of these were from form emails or postcards. These comments often specified that at least 1,000 additional acres should be removed. The sediment removal percentage of 8 percent in the proposed plan was also cited frequently and was said to be unacceptable.

The form comments seen most frequently are:

- “The proposed cleanup of the Portland Harbor is a big win for industry and a bad deal for the public. EPA’s cleanup proposal tackles just 8 percent of a site area that is 100 percent toxic. A more aggressive plan is needed to prevent even more harm to human health and the environment. On behalf of all people who rely on the river for food, recreation, employment and culture, I urge EPA to implement a plan that: Moves quickly and sustainably reduces contaminants causing harm to Willamette and Columbia River resources. Includes ongoing monitoring and cleanup upriver and downriver from the site. Contributes to healthy fish that are safe to eat for all people. Holds polluters accountable for creating a safer Portland Harbor.”
- “At least 1000 acres of the most highly contaminated sediment should be dredged and removed to achieve the Fish Consumption Advisory goal” (or a slight variation of this).

The remainder of the comments were personal comments urging EPA to do more. Many of them were similar to the form comments in content but included personal thoughts on why doing more was important to the commenter.

Representative comments from this group include:

- “I am disappointed with EPA's proposed cleanup plan for the Willamette River. I live in SW Portland close to the river, and am aware of the contamination that spreads through the ecosystem as a result of the toxic levels of the river. This is a unique and rare opportunity to have meaningful and lasting cleanup and environmental restoration. I do not believe the current proposed cleanup plan goes far enough to properly clean up the river. This opportunity should not be wasted. The Willamette River is unsafe for fishing and swimming. I believe the proposed plan should be modified to include additional dredging and other measures in order to ensure a proper cleanup is undertaken.”
- “I am very disappointed in the thoroughness of EPA's cleanup plan. It does not go far enough to properly cleanup the river, due to a "balancing formula" which weights minimizing costs more than extent of cleanup.”

- “I am writing in regard to the proposed superfund cleanup. We need to clean up ALL of the polluted areas, not just some. It’s difficult to fathom why this is even up for debate: The draft cleanup plan leaves far too much of the river contaminated for generations to come.”
- “I believe the Draft Cleanup Plan isn't adequate in its current state to sufficiently recover the Willamette River Superfund Site. More than 65 known toxic chemicals are present throughout this stretch of river which pose serious chronic and acute health effects to humans, fish and wildlife. I would like to see EPA adopt a more aggressive approach to remediation. Specifically, I recommend even more dredging to remove contaminated sediment from the Willamette River. The current plan proposes to remove sediment from less than 10 percent of the area -- that doesn't go far enough.”
- “I do not feel that the proposed plan goes far enough to remove toxic sediment. I am deeply concerned that we are bringing our waterways to the brink of total devastation. I live in Portland and the Willamette is a key part of my life. I go to the Selwood Dog Park and swim from my friend's houseboat. I am concerned that the toxic sediment is too dangerous for the species on the river.”
- “I feel that people might say, well, where is your evidence that this is not enough. I think that the onus is on the people saying this plan is enough to show indisputably that it is enough, and it's not. I feel like the numbers, the amount of sediment that is taken out, the amount of years it's going to take is pulled out of a hat, and it's not adequately grounded. I'm very concerned.”
- “I have raised 4 children in Portland in the last 28 years and wish we could have felt safe swimming and fishing in the Willamette. For the sake of future generations, please work to remove the contamination completely form the river, not just 8 percent.”
- “Why not take this opportunity, for ourselves, for our wildlife, and for our ecosystem, to do a proper job of it? I can think of many reasons to not do otherwise, otherwise being what this plan proposes. The current plan is insufficient. I encourage EPA to consider a stronger plan, with more dredging and proper disposal of contaminants and with less reliance on covering them up or, more importantly, simply leaving them be in order for them to be disposed of (only perhaps, and oh so slowly, and not ever removed properly from the sediment and water of the rivers and ocean) by the river. People and wildlife are suffering from this contamination every day.”

### **EPA Response**

EPA sought in its proposed plan (USEPA 2016c) and in the selected remedy to develop a cost-effective alternative that balances several important factors, including maximizing risk reduction in the quickest timeframe while minimizing to the extent possible the impacts to the environment during construction; disturbance to the habitat for benthic invertebrates, fish, and wildlife; and long-term restrictions on human uses that can be allowed at capped areas. Due to the concern of the vast majority of commenters that the proposed plan left too much contamination for monitored natural recovery (MNR) as well as other issues raised with the proposed plan alternative, EPA has selected Alternative F Modified, which will actively address an additional 103 acres of contaminated sediment. Thus, the selected remedy will remove up to approximately 3 million cubic yards compared to the roughly 1.7 million cubic yards of sediment removed under Alternative I.

Contamination at the Site is not evenly distributed. There are high levels of contamination in certain areas that represent an ongoing source of contamination to the Willamette River and downstream.

EPA's selected remedy will actively remediate these higher concentration areas through a combination of dredging and capping. The selected remedy reduces risks due to people eating contaminated fish by 76 percent by dredging and capping 18 percent of the Site (394 acres of 2,167 total acres). Details about the number of acres addressed through cleanup, volume of contaminated material dredged, and other information for Alternative F Modified is included in Appendix IV of the ROD.

Dredging plays a significant role in the selected remedy as do capping, MNR, and enhanced natural recovery (ENR), based upon engineering considerations of site conditions (such as potential for erosion, sedimentation from upstream, and observed trends in natural recovery). The selected remedy calls for the highest levels of contamination to be removed through dredging (up to approximately 3 million cubic yards of material) or to be isolated through capping (176 acres). ENR and MNR are employed only in areas with lower levels of contamination. EPA's analysis of alternatives shows that any larger, removal-based remedy beyond Alternative F Modified would not substantially improve public health and environmental protection but would take a good deal longer; cost substantially more; have greater short-term impacts to aquatic organisms in the waterway and to the community surrounding the waterway because of dredging activity; and require the processing, transporting, and landfilling of millions of additional cubic yards of sediment with low levels of contamination.

Reductions in the sediment contaminant levels remaining after active remediation are expected to occur as cleaner upriver sediments deposit on surface sediment in the Site during low-flow periods and bury and dilute contaminated sediment. These sediments may be diluted to levels below risk thresholds, become buried below the depth where exposures to organisms can occur, or potentially be dispersed downstream during higher flow periods. Monitoring will be performed to measure progress toward achieving cleanup levels. The results of the monitoring program will be used to determine whether any additional actions are required to achieve the cleanup levels.

### 2.1.2 Support for Less Cleanup

#### Comment Summary

A total of 104 comments expressed a desire for less aggressive cleanup. They were almost always part of individual letters containing multiple comments, and the support for less was often paired with other topics found in this responsiveness summary, like danger to workers and economic harm to adjacent businesses. Commenters generally believed that Alternative I would be very disruptive and could potentially spread contamination downstream and uncover sediments that were already covered by natural deposition. Many comments referred to a study stating that natural recovery of the river is occurring and that the contaminant concentrations had already been reduced by 40 percent.

Representative comments include:

- “The Portland Harbor PRAP goes too far in recommending Alternative I. This Alternative does not appropriately balance risk reduction with cost effectiveness. Over a billion dollars will be spent to protect a population that is difficult to quantify in terms of who is eating fish and how much fish is being eaten. EPA's approach should focus on hot spot remediation more in line with Alternative B or D. Expanding remediation will not provide a significant risk reduction relative to cost. EPA needs to update their data used for decision making as recent data shows significant improvement in the river. In addition, EPA has to incorporate and evaluation of sustainability in the remedy to demonstrate the real cost to the environment and economic cost. EPA needs to look

hard at what it has proposed and reevaluate the approach to produce a better remedy that doesn't burden Portland.”

- “In addition to being a small business owner, I am a geologist and I am very concerned about the plan that EPA has proposed. They plan to dredge 167 acres and remove 1.9 million cubic yards from the Willamette and transport it to a landfill. As a study found in 2014, natural processes at work in the Willamette have already reduced contaminant levels by at least 40 percent. The contaminated sediments, once they're compacted by these natural processes, usually won't leach out.”
- “Less invasive cleanup methods sound like the better option, as has been done in the past in other areas. It seems like these methods would also work in this situation, especially considering the river has begun to restore itself naturally. Recent reports show there has been a 40 percent reduction in contamination levels. EPA is putting too high a priority on trying to make the river completely clean at an unreasonable cost, instead of allowing the natural process to continue.”
- “A lot of things have changed in the last 12 years and if there is any evidence natural restoration is working, the river should have a chance to heal itself. I agree with the course of action the Army Corps of Engineers recommends: waiting to see how natural processes work and then using more aggressive measures like dredging in a limited manner as necessary.”
- “Please do NOT dredge. Instead, let’s restrict businesses from discharging waste into the river. Dredging kills wildlife for miles - it’s happened before. We are 5 generations strong in North Portland - it has to stop!”
- “Dredging should be minimized, since “[l]imited data exists on the depth of contamination at the Site.” (Plan, p. 29.) Dredging sediments that do minimal harm in place is problematic—the dredging activity disturbs undredged sediments, potentially redistributing them to locations where they will be more harmful. It also requires a location to deposit them, which creates its own set of problems, including construction of a confined disposal facility. (See “Disposed Material Management” discussion, proposed plan p. 31.) If the extent of dredging cannot reliably be predicted, dredging in any areas other than those already dredged to maintain the navigation channel should be avoided.”
- “I live in the same neighborhood in Southwest Portland that I grew up in. I believe the Willamette River cleanup proposal is a serious mistake. It does not approach making sense to resurface buried pollutants and risk contaminating the river all over again. That would endanger the people and wildlife of Portland for no discernable reason. EPA should devise a plan that builds upon natural decontamination rather than reversing it.”
- “I am opposed to the costly EPA plan to dredge out a big chunk of the Willamette River. If they dig down into the riverbed, they would bring up more sediment and pollutants that would contaminate other parts of the river.”
- “If the river is correcting itself, it should be allowed to do so with as little input from humans as necessary. We should not be invading Mother Nature’s process to the point that we’re simply pushing all of that pollution and contamination back to the surface and out into the air.”

Two personal comments were received that spoke to the concern that proposed cleanup levels were not attainable. Specifically:

- “Proposing remediation levels that are below current background levels of presence for some contaminants, along with high fish consumption estimates for a very small segment of the population create basically unattainable level of remediation to be borne by the currently identified operators along the river.”

### **EPA Response**

EPA has determined that contamination found in sediment, groundwater, surface water, and biota in the Site presents an unacceptable risk to human health and the environment. There is no more recent data that would indicate there is no risk at the Site.

Active dredging, capping, and ENR will be performed under the selected remedy to address principal threat waste (PTW) and the worst of the contamination identified in the river; however, the larger area of contaminated sediment, covering 1,774 acres, will be remediated through MNR. It is important to recognize that the selected remedy relies on active cleanup to achieve the sediment remedial action levels (RALs) developed in the feasibility study, and MNR is being relied upon to further reduce contaminant concentrations to the more stringent cleanup levels and fish tissue targets. However, MNR has not been shown to be effective on its own to address some of the most highly contaminated areas in the harbor. As described in Appendix D8 of the feasibility study, six lines of evidence considering a range of physical and anthropogenic factors were evaluated to assess the viability of MNR for each sediment decision unit (SDU). Scores of -1, 0, or +1 were assigned based on each line of evidence representing whether deposition was unlikely (erosional), neutral (transitional), or likely (depositional), respectively. The scoring framework using these lines of evidence and the scores for each SDU are presented in Table D8-2 and Table D8-3 of the feasibility study report (USEPA 2016b) Appendix D, respectively.

While active remediation within the river and along the river bank, such as dredging, has higher short-term impacts than MNR, best management practices will be implemented to minimize contaminant releases from the remediation area. Engineered control measures (such as silt curtains and rigid containment) will also be implemented, where necessary, to limit contaminant releases.

## **2.2 Community and Local Business Concerns**

### **2.2.1 Retain Local Jobs and Industry**

#### **Comment Summary**

A total of 399 comments were received on the topic of retaining local jobs and industry. About 85 percent were received as form emails or postcards from the Portland Business Alliance, Greenbriar, or another group.

Representative form comments include:

- “A big, expensive river cleanup may sound like a good idea. But it isn’t. I want to see EPA support a clean river. But I also want to see EPA support a strong Portland economy. A strong economy relies heavily on the blue-collar jobs that exist on the Willamette River. Please do whatever you can to support the river and our health but also to make sure our jobs don’t go away.”

- “Hi, I seldom write public officials but I am today because I believe in clean rivers. We need to clear up the river, but I hope EPA regulators understand that we can’t have a pristine river that gets that way at the expense of small businesses and jobs. Thank you for what you do for our environment. Please consider my thoughts and approve a plan that’s good for our economy as well.”
- “Our Gunderson operations in Portland feature the only sideways launch for marine vessels west of the Mississippi and provide nearly 12,000 family-wage jobs. I urge EPA to support a more cost-effective plan that relies on the most current data, preserves local jobs and protects from unnecessary cost increases.”
- “I SUPPORT A CLEANUP OF THE LOWER WILLAMETTE RIVER THAT PROTECTS THE HEALTH OF PORTLANDERS AND THE ENVIRONMENT AND IS DONE COST-EFFECTIVELY. The Willamette River is many things to Portlanders - a place for recreation, a home for wildlife and also an industrial harbor, Oregon's largest seaport. Portland's working harbor is important to me. Nearly 30,000 people are employed in Portland's working harbor, jobs that must be preserved during the cleanup.”

The remaining 58 comments were personal comments from trade groups, businesses, and residents. Representative comments include:

- “The cleanup will be funded largely by local businesses, local utilities and local and state government. The impacts to the region of diverting capital dollars to a cleanup effort will mean employees will not be hired or lose their existing job, capital investments are not made and operational and infrastructure efforts will be scaled back or not happen at all.”
- “The Oregon Building and Construction Trades Council is an umbrella organization for approximately 25,000 union construction workers in Oregon. We recognize the proposed plan marks a significant milestone in a very long process for the Site. We support a river cleanup that protects the health of Portlanders and the environment and is done cost-effectively.... Nearly 30,000 people are employed in Portland's working harbor, jobs that must be preserved during the cleanup.”
- “The Portland Business Alliance (Alliance) represents close to 1,900 small and large businesses that employ 350,000 workers in the Portland region. The Alliance supports cleaning up the Site to protect public health and the environment. The Alliance also supports doing so in a way that is mindful of the impacts on the economy, jobs and other important local priorities. The cost of the cleanup will be borne throughout the community. In 2013, the Alliance commissioned a study that looked at the economic linkages from marine industrial businesses. The study analyzed vendors and suppliers to five large marine industrial businesses. At the time, 42 percent of the goods and services purchased by these five businesses were derived from local businesses, often small businesses. In all, about 300 local businesses are part of the supply chain for just five large marine industrial businesses.”
- “I've lived in Portland a very long time and I don't want to see our economy hurt by EPA's river cleanup plan.”
- “In recognition that there are many comments pushing hard on all sides, I want to encourage a broader view by the agency. I strongly support balanced, collaborative efforts to clean up Portland's Willamette River. With a fragile local economy so strongly connected to global trade

combined with a community ethos that emphasizes environmental protection and sustainability, we need to make sure the cleanup of hotspots is effective, Portland’s blue-collar harbor jobs do not suffer, and the overall cleanup plan is not too expensive.”

### **EPA Response**

CERCLA, or EPA’s two threshold criteria for selecting a Superfund statute, establishes five principal requirements for the selection of remedies. Remedies must:

- Protect human health and the environment
- Comply with applicable or relevant and appropriate requirements (ARARs) unless a waiver is justified
- Be cost-effective
- Utilize permanent solutions and alternative treatment technologies or resource recovery technologies to the maximum extent practicable
- Satisfy a preference for treatment as a principal element, or provide an explanation in the ROD why the preference was not met.

Within this context, EPA has nine remedy selection criteria described in the Superfund statute and its implementing regulations, commonly known as the National Contingency Plan or NCP. The individual criteria are either threshold, balancing or modifying criteria. EPA’s threshold criteria for selection of a Superfund remedy are:

- Overall protection of human health and the environment
- Compliance with applicable or relevant and appropriate requirements of federal and state environmental laws

Once these two criteria are satisfied, EPA determines the best balance of tradeoffs among the alternatives with respect to five balancing criteria, which are long-term effectiveness; short-term effectiveness; costs; reduction of toxicity, mobility and volume; and implementability and two modifying criteria, which are state and community (including tribal) acceptance, which includes a wide spectrum of often competing concerns.

EPA appreciates the concerns of the local workforce and businesses as important segments of the community as well as the desire expressed in many comments to retain the industrial/manufacturing base in this area. While there is no specific remedy selection criterion with respect to impact on local economies and business, EPA does consider these concerns in the broader context of its remedy selection criteria. For example, EPA considered current and reasonably anticipated future land use when developing the selected remedy to ensure that the remedy will be protective in the long term and will work with landowners and businesses through the design and implementation of the selected remedy. EPA will encourage the companies performing the cleanup to keep cleanup jobs with locally trained workers as much as possible and will offer resources where possible to teach special hazardous materials skills necessary to perform the cleanup. As EPA progresses through the design and construction of the remedy, it intends to work with local businesses to minimize potential adverse

impacts on them and to the local economy. The agency will draw on the many lessons learned from other communities and cleanups implemented under CERCLA to minimize the effects.

EPA is aware that other entities have been studying the economic impacts of the cleanup. For example, the City of Portland commissioned a 2012 economic study specific to the Superfund cleanup entitled *Economic Impacts of the Portland Harbor Superfund Site Cleanup* (Econorthwest 2012). A City of Portland press release described some of the study's findings as: "clean-up will inject new spending into Portland's regional economy and support jobs;" and "for every dollar spent on cleanup, more than a dollar in additional spending will be generated in the Portland economy as those employed in the cleanup purchase other goods and services in the region." It is EPA's belief that moving forward with the cleanup may enable properties to be more readily developed, which in some cases may have sat idle for years due to contamination issues.

## 2.2.2 Hire Locally

### Comment Summary

Twenty-nine comments were categorized as supporting local hiring during cleanup. Many requested that local people and firms be used where possible in conducting the cleanup work at the Site. Several people suggested apprenticeship programs. These comments came from residents, local associations (Oregon Association of Minority Entrepreneurs), and local government (City of Portland).

Representative comments include:

- "Cleaning the river can provide near-term job opportunities for the local job sector, and a clean river will provide increased economic opportunities by reducing economic uncertainties and promoting development along the river. EPA's Workforce Development and Training Program provides a means to enable and enhance these opportunities, such as through grants for programs that "recruit, train, and place local, unemployed and under-employed residents with the skills needed to secure full-time employment in the environmental field". The City values and supports diversity and is dedicated to advancing equity in public contracting by increasing opportunities for State of Oregon certified Minority, Women and Emerging Small Business enterprises (M/W/ESB). We encourage and support the use of strategies that promote the use of M/W/ESB contractors and mentoring opportunities between large and small M/W/ESB firms. The City has set a goal of 20 percent of PTE awards for prime consultant and sub-consultant contracts to State of Oregon certified M/W/ESB firms. We would like to see performing parties set similar targets for the work that lies ahead. The City appreciates EPA's ongoing efforts for workforce development. However, given the magnitude and complexity of the Site, the City requests that EPA use the opportunity to expand the job development program, and provide additional resources specific to Portland Harbor for local work force training. The City would also like to see every action possible in the ROD to ensure that local companies have preferential treatment in the contracting process in all stages of the cleanup."
- "We ask that MWESB firms are given the same info, chances, incentives, and encouragement to work on the project(s) in partnership with the Contractors hired by you."
- "The ROD should include a mechanism for local workforce training and hiring to ensure resources spent on mitigation efforts can have a positive employment impact on the communities most affected by the contaminated site."

- “EPA and DEQ should aim to offer economic benefits from remediation, such as employment and training opportunities, to the local community.”
- “I would like EPA to encourage the large companies that will be making millions of dollars coming into Portland, as well as the large industries here that will be working on the project, require them to provide apprenticeships and job training for local community members.”

### **EPA Response**

EPA expects that the cleanup work will be conducted by the PRPs under oversight from EPA and the Oregon Department of Environmental Quality (DEQ). EPA will encourage the PRPs and their contractors to hire locally but cannot require parties to do so. EPA will be using contractors to support the agency and aid in the oversight of the design and construction activities. These contractors have federal contracting goals related to the use of small businesses as well as businesses owned by minorities, women, and veterans and EPA strives to use these firms whenever possible.

Additionally, EPA is often able to provide job training and employment opportunities for people living in communities affected by Superfund sites through the Superfund Jobs Training Initiative (SuperJTI) program. EPA’s goal through the SuperJTI program is to work with all communities affected by the Site (including communities with environmental justice concerns) to develop job opportunities that remain long after construction is complete at the Site. EPA is already exploring how SuperJTI could be applied at the Site.

### **2.2.3 Move Quickly and Don’t Delay Cleanup**

#### **Comment Summary**

A total of 740 comments were received that urged EPA to move quickly and not delay the start of the project. Almost all (about 97 percent) were received as post cards (or a few emails) that stated “*I urge the EPA to implement a plan that moves quickly and sustainably reduces contaminants causing harm to Willamette and Columbia River resources.*” Several comments expressed the sentiment that delaying cleanup would just end up costing more, and it was also stated that the pursuit of perfection should not be responsible for delaying cleanup.

Representative comments include:

- “The cleanup of the rivers effects so many life forms that it should be a high priority to complete quickly! Not 5 years down the road, Not 10 years down the road. This known problem needs immediate attention and the funds we pay should be directly applied for an urgent solution. The longer we delay the slow process to resolve, the more work there will be to correct.”
- “The longer it sits undone, the dirtier and HARDER to clean it becomes!”
- “It is important that we act as soon as possible so we can minimize the cost and prevent permanent damage.”
- “If the cost is too much now, how much will it cost later?”
- “Recognizing the complexity of the cleanup, and the instability of the geological structure, the immediate target should be taking action - Not Perfection.”

- “We do need something to happen and I would hate for this to drag out any longer, I'd like to see something done as soon as possible but I would like a more thorough job of cleaning up the mess. That's what's most important I think, not running blame but getting this cleaned up.”
- “The process for developing a plan for cleanup of the Site has dragged on for many years. On one side we have those demanding perfection and only perfection and on the other side those anxious to complete the process as quickly as possible at lowest cost. HOWEVER MOST IMPORTANT IS THE NEED TO MOVE BEYOND THE YEARS OF PLANNING AND DISCUSSION AND BEGIN THE CLEAN UP PROCESS AS SOON AS POSSIBLE WHILE CONTINUE MONITORING TO TRACK IMPROVEMENTS AND THE NEED FOR FUTURE ACTION.”
- “We should have already started, if not completed, this project. We're slowing our own city's growth and stopping it from flourishing like it could by not getting this resolved.”

### **EPA Response**

EPA understands the public's frustration regarding the duration of remedial investigation, feasibility study, and remedy selection. At very large and complex sites, with multiple PRPs, governmental agencies, and tribes such as Portland Harbor, the process does take a number of years. It has taken many years to characterize the nature and extent of contamination over the length of the 11-mile Site and to screen and thoroughly evaluate the potential options for cleanup in order to develop a proposed plan for cleanup. However, the public should be assured that, once a ROD is signed for the Site, EPA will move quickly to initiate next steps with the PRPs toward remedial design and cleanup. We trust the PRPs will want to proceed with the cleanup process. Working with the PRPs, state, tribes, other federal agencies, and the public, we can forge a game plan to move the design and construction process forward expeditiously. However, if an agreement cannot be reached, EPA has enforcement tools to allow the cleanup process to proceed unilaterally if necessary.

## **2.2.4 Cleanup Will Take Too Long**

### **Comment Summary**

Twenty-two personal comments were received that focused on the length of time to complete cleanup – essentially that the estimate of 20 to 30 years was too long. One commenter stated there were ways to reduce cleanup time and spoke of efforts by the Cathedral Park Neighborhood to assess community sentiment on length of time for cleanup.

Representative comments included:

- “Waiting a generation to see if fish are safe for eating is unacceptable.”
- “A 30-year cleanup plan duration exposes the public and the environment to health hazards for too long.”
- “What we need is a plan that isn't going to take 20 or 30 years.”
- “I am concerned that the draft for the Portland Harbor cleanup is proposing a partial rather than full clean up, and is proposing an overly long time frame for doing the work. Even though we warn people currently not to eat fish in the lower Willamette, people still do. We should work quickly to make the river cleaner so the fish can be eaten without harm.”
- “The timeframe suggested by EPA is that the cleanup under Alternative I will take up to 30 years. How is such a timeframe appropriate when the river has been imbued in places with toxic

contaminants for many decades? This is not well explained in the rationale for Alternative I. The US EPA should select or develop an Alternative that gets the job done in a more timely manner. Should the residents of Portland or river users be subject to increased toxic exposure just so one of the PRPs can save a few dollars over time? EPA should develop an approach that gets the job done more quickly, and reduces risk more rapidly. This is a very basic exception that benefits a wide range of people and wildlife.”

- “Thirty years is far too long to achieve full usability of the river, as well as to remove the fish advisory.”
- “Time to completion is a function of a number of variables. For example, The Cathedral Park Neighborhood, in conjunction with the graduating class of Urban Planners at PSU in the year 2015, conducted extensive polling, canvassing, and charrettes among the neighborhood to determine that residents favored accelerated cleanup and its negatives over a longer period of moderate activity. This choice was influenced by a minimal awareness of ongoing channel dredging by the Port of Portland. Additionally, multiple sites can be worked simultaneously. This has the potential to shorten the duration of the project. In the short term, workers, community, and the environment all benefit from a real time, interactive web site. Air quality needs 24 hour monitoring to protect all parties. Cofferdams, de-watering barges, hydraulic dredging, and environmental bucket dredging all serve to minimize impacts on the water column. Special consideration needs to be paid to volatilizing PCB’s.”

### **EPA Response**

EPA understands the frustration with the timeframes for cleanup to achieve its objectives. It will take time. However, because there are sensitive species, such as migrating salmon, that use the Willamette River, there are constraints on the time that physical activities for cleanup can take place in the river. Currently, the “in-river work window” approved by the state and federal resource agencies is approximately between July 1 and October 31, based on actual fish migration observations. Additionally, there are also constraints on the number of dredges, barges, and other equipment that can be used so there is not unacceptable interference with commercial, industrial, and recreational uses of the river. With these constraints in mind, physical cleanup activities, such as dredging/disposal and capping, are expected to take 13 years to complete after remedial design, assuming it is conducted continuously under those constraints.

Once the physical activities of the cleanup are complete and the highly contaminated areas are removed or capped, contaminant concentrations in sediment will be greatly reduced. There are multiple areas that will be cleaned up over the course of the 13 years of construction. Progress will happen incrementally, and at the conclusion of all the construction, EPA expects that 85 percent of the fish consumption risk is projected to be addressed—At that time, restrictions on resident fish consumption from the river (which is currently not advised) will be reevaluated and relaxed if protective. Therefore, there would be measurable improvement directly after construction. Accelerating this timeline significantly probably will not be feasible due to the constraints described above. Immediately after construction of the selected remedy, it is estimated that wildlife will be able to safely consume prey from within the Site since all non-cancer risks on a site-wide scale will be addressed. It is estimated that bis(2-ethylhexyl) phthalate (BEHP) will be at a hazard quotient (HQ) of 5 at a river mile scale and 3 at an SDU scale, very close to the target of 1 and well within potential calculation variances.

The remaining risk to people eating fish is expected to decrease over the following years as natural recovery takes place. If EPA determines that the cleanup, including the natural recovery component, is not occurring as expected, additional cleanup actions may be taken to reach the cleanup levels.

However, in consideration of public comments that sought more cleanup and more certainty of achieving cleanup goals, EPA has selected a cleanup that addresses more contaminated sediment by dredging and capping, which upon the end of construction, gets the sediment much closer to the cleanup levels. Thus, it is expected to take less time for MNR to work. Because the selected remedy involves more dredging and capping, the construction timeframe has increased from 7 to 13 years.

## 2.2.5 The Community Needs Accurate Cleanup Costs

### Comment Summary

Nineteen comments were received that addressed the accuracy of costs derived for the feasibility study. Half were included in form emails and stated:

- “I urge EPA to get their cost numbers right so Portlanders are educated about the costs of cleanup and its benefits. The cleanup of the Portland Harbor arrives at a time that our city is growing and we face many critical affordability issues. We need a final cleanup plan that relies on accurate cost estimates and remains cost-effective.”

The remainder were personal comments and included a belief that costs were underestimated, unreliable, and overly optimistic. It was also clear that the commenters believed that the costs presented in the feasibility study and proposed plan were intended to be actual cleanup costs.

Representative comments include:

- “We are concerned about the ultimate cost of cleanup and ensuring that the true costs and benefits are transparent to Portlanders. We believe some of EPA’s cost assumptions are overly-optimistic and resulted in a final price tag that is not accurate.”
- “We believe some of EPA’s cost assumptions are overly-optimistic and resulted in a final price tag that is not accurate. Our livelihoods depend on providing accurate cost estimates.”
- “We believe that the cost estimate of the preferred alternative (\$746 M) issued by EPA dramatically understates the true cost of performing the proposed remediation, which will likely be more than \$1.5 billion. It includes a number of unrealistic assumptions: (1) 24/6 dredging; (2) seamless dredging with no breaks to reposition barges between cleanup areas, install sheet pile walls or account for unforeseen circumstances; and (3) availability of necessary dredge and barge equipment during limited fish windows. Furthermore, it is unclear how the agency was able to cut its prior cost projections in half in a matter of months while changing little in the way of cleanup action. EPA’s preferred cleanup alternative needs to be cost-effective and proportional to realistic assessment of the benefits that will justify the significant diversion of resources to cleanup actions. It is imperative that EPA recognize and considers these important economic impacts.”

### EPA Response

EPA recognizes that the intended purpose and use of cost estimates during a feasibility study for remedial alternatives may be misunderstood by those not familiar with the Superfund process, leading to the incorrect perception that feasibility study cost estimates are “inaccurate” or not the “true” costs. The stated purpose for feasibility study cost estimates in EPA’s *“A Guide to Developing and Documenting*

*Cost Estimates During the FS*" (USEPA 2000) is to compare remedial alternatives during the remedy selection process.

The information provided in the cost estimate is based on the best available information regarding the anticipated scope of the remedial alternatives, and thus the issue may be the technical assumptions and not the costs that they reflect. The stated accuracy in the 2000 guidance for feasibility study cost estimates at the detailed analysis phase is +50 to -30 percent of actual cost. The estimates were accurate for the level of detail and scope of the alternatives development in a feasibility study. The cost estimates are developed to reflect the understanding of the alternatives as described in the feasibility study given the understandable uncertainties that exist and will continue to exist even after a decision on a remedy approach is made, prior to design and construction.

The cost estimates were reviewed by EPA's National Remedy Review Board (NRRB). The NRRB reviewed the feasibility study cost estimates in November 2015 and indicated that the costs presented were generally in the range of costs at other contaminated sediment Superfund Sites (AR Doc#100001536). The NRRB, while determining that the costs used were reasonable when compared to other contaminated sediment Superfund sites, did recommend further evaluation of specific assumptions and related costs. EPA reviewed comments pertaining to cost estimates and made changes to assumptions for all alternatives and updated the cost estimates, as appropriate, to better reflect the anticipated scope of a future remedy for the Portland Harbor Site as it became further defined between November 2015 and the 2016 drafts of the feasibility study reports. For instance, EPA reviewed assumptions pertaining to treatment of contaminated sediment for consistency with early actions and also reviewed unit costs for remedy components such as capping and dredging to reflect consistency with the productivity rates anticipated in EPA's evaluations.

Although there is a perception that the remedial alternatives did not really change between November 2015 and June 2016 because the components used were similar, there were significant changes in assumptions related to quantities of the components (such as, reduced depths of dredging, reduced quantities of sediment treated prior to disposal, reduced extent of river requiring mitigation). Reevaluations of these assumptions, specifically due to more refined development of the alternative's scopes, resulted in lower overall costs in the feasibility study presented in July 2016 than as presented to the NRRB in November 2015. EPA's position is that the cost methodology and sources used in the feasibility study report (USEPA 2016b) meet the stated accuracy range. This reevaluation of cost was reasonable given the significant changes in assumptions made for remedy components within the alternatives. In addition, per the feasibility study cost guidance, EPA uses cost factors for professional and technical services as well as contingency factors to account for unknown or unforeseen conditions that can affect the total cost. Detailed cost backup and individual cost summaries for each alternative presented in Appendix G of the feasibility study report meet the documentation guidelines presented in Chapter 6 of the 2000 guidance.

## 2.2.6 Cleanup Will Create Economic Impacts for Local Businesses

### Comment Summary

Eighty comments were received that focused on short-term impacts to local businesses and the economy during cleanup. They were all personal comments that were part of letters received from the Portland residents and the business community. Commenters feared that the impacts of the cleanup on local businesses (loss of customers and revenues) and resource users (loss of access) during

construction were unacceptable. Many of the commenters appeared to believe that large portions of the river would be shut down or impeded by dredging or other intrusive activities for a long period of time.

Representative comments include:

- “To see (the Willamette) torn up for decades because of a restoration project that is not really necessary would only serve to hurt the city's economy. I would not continue to visit the area while it was an active construction zone. Not only will EPA's plan hurt out economy in terms of businesses losing money, but it will also trickle down and have negative impacts on our residents.”
- “The Willamette and the waterfront are essential parts of what makes Portland a great place to live and also a great place to visit. A project like the dredging proposed by EPA could not help but have a negative impact. Years of dredging and construction activity would destroy what makes the waterfront attractive. I'd have to seriously reconsider if I wanted to keep going there, especially if it were noisy. I'm sure other residents and tourists would feel the same.”
- “If I owned a business on the riverfront, I wouldn't enjoy having loud, heavy machinery outside my building twenty-four hours a day, and I'm sure it will affect business for the worse. This dredging project could be going on for decades, which is overboard and unnecessary. Businesses that had nothing to do with contaminating the river in the first place should not have to pay such a steep price. EPA should consider an alternate plan, based on advice from people and businesses in Portland.”
- Keeping dredging machinery in virtually constant operation for years means the river will be closed most of the time. A good friend of mine runs the Portland Kayak Company, and his business would be completely finished if that happened. Indeed, it would mean disaster for Portland's entire shipping industry.”
- “It would affect businesses tremendously and many would likely shut down. People would probably not make the extra effort required to travel to the affected businesses if the easiest routes were blocked. If areas of the river are closed, businesses that rely on it would suffer, and when one area of the economy is affected, all areas are affected. This dredging plan is significantly more strict and expensive than what has been performed in other areas with similar contamination.”
- “The ROD should affirm that seasonal timing would be considered to account for busier and slower period of business, facility operations, and prevent adverse economic impacts.”

### **EPA Response**

EPA appreciates the concerns of river users about the impacts of the dredging and other construction components of the cleanup. EPA's decision-making process considered such impacts in its evaluation. The need to balance disruption of recreational and commercial use of the river while addressing risks to fish consumers and the wildlife and fish that live in the river has been considered in EPA's evaluation of the alternatives and will be an ongoing consideration as the selected remedy is being designed and constructed.

The selected remedy addresses approximately a 10-mile stretch of the lower Willamette River, consisting of approximately 2,167 acres. However, active cleanup would take place in smaller areas that make up approximately 394 acres, or about 18 percent of the Site. The amount of time cleanup activities

may occur in the river is likely to be constrained to within the in-river work window that will be coordinated with state and federal resource agencies but may be as short as, July 1 to October 31. Cleanup activities will take place within these localized areas at different times throughout the construction period, as determined during remedial design. As such, portions of the river will be inaccessible for some portion of the construction period, but other portions would remain open.

Cleanup activities, including the use of dredges and barges generally should be consistent with existing uses of the river in terms of the level of noise, lighting, and human activity. During the construction period, there would be increased barge traffic as barges transport dredged material from the active cleanup area downstream. Cleanup activities with the potential to restrict navigation in the harbor channel will be coordinated with the U. S. Army Corps of Engineers (USACE), U.S. Coast Guard, and other stakeholders during remedial design.

EPA recognizes the need to attempt to minimize interference where possible with commercial, industrial, and other uses of the river and will take into consideration those operations and constraints during remedial design and construction. EPA and the performing parties will work with landowners and businesses to minimize impacts, such as berthing disruption, through the design and implementation of the remedial actions. Seasonal timing will be considered to account for busier and slower periods of business if possible, but would not supersede other timing required by ARARs, like in-river work windows for protection of listed species.

During construction, areas with active cleanup activities will be inaccessible for the duration of cleanup in that portion of the river. Placement of caps in some nearshore areas may result in permanent restrictions on the use of anchors, spuds, and other equipment in order to protect the caps. However, existing industrial uses and commercial shipping within the Portland Harbor Site already limits accessibility for recreational users in many of these areas. Section 2.2.1 of this responsiveness summary contains more information on economic benefits of the cleanup on the regional economy, jobs, and development of idle properties along the river.

### 2.2.7 Cleanup Will Cause Local Taxes and Utility Rates to Rise

#### Comment Summary

A total of 188 comments were received that suggested that utility rates and/or taxes would rise as a result of the cleanup. About 65 percent of these were in the form of a pre-printed postcard that stated:

- “Please accept my comments to the PH Superfund proposal released by EPA in June. As an employee of the Greenbriar Companies, I am concerned that the plan is too extreme. It negatively impacts our company's operations and will increase my own utility bills and water/sewer fees.”

The remaining comments were personal comments from local businesses or residents, expressing hardships they would feel if taxes and/or utilities increased. Representative comments from businesses include:

- “If EPA approves a big, expensive cleanup, I am worried that it will lead to higher costs for small companies and Oregonians. We also have utilities who will pay part of the cost and I’m worried a big cleanup bill would lead to higher utility bills. Thank you for recognizing that there is a real cost to employers for this cleanup. And thank you for everything you’re doing to protect our river. It’s a terrible idea to approve a cleanup plan that may hurt jobs and is so expensive.”

- “I am the President of Gann Brothers Printing, a third-generation printing company that has been in Portland for 115 years. Raising taxes and utilities to pay for a billion-dollar cleanup would kill us. Most of our machines are run by electricity. During the summer, our electricity bills run close to \$500 a month; during the winter, they run close to \$800 a month. We can't afford them to go up. Higher operating costs make it even more difficult to compete with national companies like Vista print.”
- “As a small business owner, I can tell you that this plan will harm individuals and the economy as a whole. I'm a partner at Barbo Machinery & Supply. Today, there are six of us working here. If business taxes rise to fund this project, salaries will have to be cut. We do our best to project our budget out for two to three years, but that kind of hidden tax isn't good.”

Representative comments from residents include:

- “As a retired person on a fixed income, I am already paying enough money to the city of Portland as it is. I don't want to be forced to pay any more in taxes because of the cost of this project. I'm in favor of a lower-cost alternative, but Portland residents need to have their voices heard.”
- “Increasing taxes to complete a project that doesn't guarantee resolution is not a project many will support. When you live on a fixed income like my wife and I, every single dollar counts. I can't wait to get my big 2.5 percent social security raise next year. That should tell you just how much every penny counts for taxpayers. It costs me \$4,200 a year just to live in my own house, and that doesn't include insurance, the water bill, sewer, or anything else. We just plain don't have the extra money to pay for something that will not fix anything.”
- “The huge cost of EPA's plan would take too much money out of the economy that we just don't have. This plan would result in higher taxes for Oregon residents. I am retired, but my husband still works. We can't afford any more taxes, period. If taxes were to increase, my husband and I would have to sell our home.”

### **EPA Response**

EPA's two threshold criteria for selection of a Superfund remedy are: (1) overall protection of human health and the environment and (2) compliance with the substantive applicable or relevant and appropriate requirements of federal and state environmental laws. Once these two criteria are satisfied, EPA determines the best balance of tradeoffs among the alternatives with respect to balancing criteria, one of which is cost, and modifying criteria (which includes a wide spectrum of often competing concerns). Cost estimates developed for the cleanup will be refined during the remedial design phase. Within the context of the Superfund statute and regulations, the sources of funding for remedy design, construction and maintenance are not within the scope of criteria that EPA can consider in making remedy decisions, and EPA cannot address questions of funding or liability in any detail at this time.

Over 150 parties have been identified as potentially responsible for the costs of investigation and cleanup of the Site. Some public utilities and the city and state are included in that group. PRPs may seek to pass some of the cost on to their customers, resulting in higher utility bills. It is unclear at this time to what extent this will occur. EPA intends to request all PRPs to participate in funding and performing the cleanup, which will spread the cost amongst many parties.

## 2.2.8 Implement the Cleanup Safely

### Comment Summary

Twenty personal comments were received on this topic. Commenters were interested in ensuring that the remedial action be completed as safely as possible. Their primary concerns centered on endangering the health of local residents and workers through the release of contaminants to the air and endangering environmental health via release of contaminated sediments while dredging. Suggestions included air and water monitoring, best management practices, meetings with the community, consultation with the University, and others. It was stated that EPA should require use of best practices to avoid off-gassing and volatilization of toxic substances, and ensure that workers are trained in these practices. Thoughts for the remedial design included that EPA should require dredging by environmental/closed buckets and specification of which near-shore areas should be dredged within sheet pile (or other effective) enclosures.

Representative comments include:

- “As specified in “Common Elements of All Alternatives” it will be important for the remedial design plan to require dredging by environmental/closed buckets to minimize release of contaminants to the water column (Plan, p. 28). Likewise, depending on contaminant concentrations and mobility, EPA’s final plan should specify which near-shore areas should be dredged within sheet pile (or other effective) enclosures so that resuspended contaminants are not dispersed to surrounding river areas. “
- “This needs to be organized by existing coalitions who must insist on coordination between local, state and federal authorities. These entities must insist on air and water quality monitoring while this dredging takes place until the contaminants are safely transferred to a toxic dump location well moved from our fish and water resources. The safety of these workers and impacted neighborhoods need to be attended to until the contamination is removed. “
- “During the entire length of cleanup process, require the most effective fuel/emissions filters available and ongoing monitoring to minimize exposure for all cleanup-related activities, including but not limited to freight, dredging, barges, and other equipment. If air toxins are found to exceed acceptable levels, immediately take measures to intervene. Ensure the health and safety of people and the environment in the transport and disposal of toxic substances Do NOT dispose of contaminated sediment in a way that will negatively impact the health of people living or working near the disposal site. Use known best practices to avoid off-gassing and volatilization of toxic substances, and ensure that all workers are trained in these practices.”
- “Atmospheric release of polychlorinated biphenyls (PCBs) is not included in the EPA analysis or proposed plan. Inhalation of PCBs during the remediation process can cause harmful health effects in people. The proposed plan should address and include air monitoring during and after the removal and remedial actions.”
- “The contaminants need to be removed using the utmost caution so as not to contaminate North Portland's already unhealthy air even more. Air monitoring is imperative while dredging is going on.”

### EPA Response

EPA is focused on protecting the health and safety of local residents and workers and minimizing potential impacts to the environment throughout remedy implementation. During implementation of the cleanup, worker safety requirements must be complied with, and water quality standards will be met. Air emissions, if any, will be monitored as necessary.

During the remedial design, site-specific plans will be developed to address potential issues and document best management practices and other procedures for protection of human health and the environment. Health and safety plans by parties performing the work are required to be put in place. Plans will be developed for conducting air and water quality monitoring during dredging and other activities with the potential to release contaminants. Air monitoring will be conducted at the work area and along its perimeter likely at the outset of work and where necessary as work continues. Water quality monitoring will also be performed during dredging and other in-river activities, which might include turbidity, chemical, and other monitoring. In the unlikely event that unacceptable levels of contaminants are detected, operations will be stopped and measures will be taken to promptly address such releases.

Contingency plans outlining corrective actions that will be taken to correct damage to the environment due to accident, natural causes, or failure to follow procedures will also be prepared. Methods for implementing green and sustainable remediation practices (such as, reduce vehicle emissions and fuel consumption, maximize efficiency of material transport/disposal, promote recycling, and analyze haul route proximity to schools) will also be developed during remedial design which will help to minimize impacts to the community.

## 2.2.9 Improve Opportunities for Public River Use

### Comment Summary

Thirteen comments were received regarding public access to the river, and all requested that access be improved to make recreation easier as part of the cleanup. About half were received as part of a post card mailing and stated:

- “More access points should be created to make recreation on our river easier.”

The remainder were personal comments. One person referenced the increased access created by the installation of the Big Pipe upriver and other people believed that the PRPs currently limited access and that EPA could improve that situation.

Representative comments include:

- “There are opportunities to enable people to get to the Willamette River, and utilize what it has to offer at multiple properties along the Portland Harbor stretch. One of the main constraints to access has been the unwillingness of some landowners to enable to public to gain access to the river. We feel that there are opportunities that are inherent in the development of the cleanup process, and that can be prescribed in the ROD, that can enhance and improve access at multiple sites along the river.”
- “Improved River Access. As part of the remedy EPA should include provisions for improved access along the river. There are opportunities to enable people to get to the Willamette River, and utilize what it has to offer at multiple properties along the Portland Harbor stretch. One of the main constraints to access has been the unwillingness of some landowners to enable to public to

gain access to the river. We feel that there are opportunities that are inherent in the development of the cleanup process, and that can be prescribed in the ROD, that can enhance and improve access at multiple sites along the river.”

- “Public Access: Increase access to public lands along the river. Prioritize impacted communities – including youth – in the design, cleanup, restoration, and development of new sites.”
- “The installation of the Big Pipe upriver has allowed a group of us to safely swim in the Willamette River for the past three years. As part of the Human Access Project we support conservation, education and stewardship of the Willamette River and its entire watershed. We are thrilled to be able to access at least parts of the river already.”
- “Cleanup actions should support improved human access to the river where it is consistent with ecological and economic needs.”

### **EPA Response**

CERCLA authorizes EPA to take response actions to address risks to human health and the environment from releases or potential threats of releases of hazardous substances. In general, EPA does not have authority to require permanent public access through privately owned land or to specifically develop additional public access points because such requirements generally are not related to reducing risks to people or ecological receptors. However, EPA’s experience at other Superfund sites is that either during or after remedy implementation, there may be opportunities to enhance access of future use beyond what would be required by the selected remedy, which can be discussed. EPA will ensure that the design of the remedy accommodates reasonably anticipated future uses to the extent possible while still achieving all cleanup objectives, including public access areas where owners and municipalities plan for such access.

## **2.2.10 Address Concerns of Sauvie Island Residents**

### **Comment Summary**

Comments were received from members of the Sauvie Island Grange. The comments asked that EPA address the concerns of the local inhabitants of Sauvie Island about the effects of Site contaminants from upstream on their drinking water wells and on the parts of the Willamette River along Sauvie Island that are used for docking houseboats and for recreation. The letter also expressed concerns about effects that are short and long-term downriver of the Site and states that there is existing contamination.

### **EPA Response**

EPA shares commenters’ concerns about providing for a remedy that addresses risks to the health and well-being of everyone who lives near or uses the Willamette River. The selected remedy extends downstream to river mile (RM) 1.9 and fronts a portion of Sauvie Island. The remedial investigation report (USEPA 2016a) summarizes the nature and extent of contamination within the in-river portion of the Site. The report includes the baseline human health and ecological risk assessments and identifies the higher risk areas along the Willamette River.

During the remedial investigation, sediment samples were collected from river miles 0 to 3 along Sauvie Island as well 1 mile downstream within the Multnomah channel. These investigations can be found summarized in Table 5.6-2 and Section 2.1.4.1.8 of the remedial investigation report. Further, sample locations and results are summarized on Figures 1.2-6a-b to 1.2-18a-b of the feasibility study report (USEPA 2016b). While the samples taken along Sauvie Island do not cover the entire extent of the Island,

the samples represent portions of the island closest to the upstream contamination and therefore more likely to have higher contamination levels. Based on the sample results, the areas bordering Sauvie Island were determined to have a much lower risk than the upstream areas identified for further cleanup and feasibility study analysis.

Specifically:

- EPA collected fish samples from downstream of the study area (river mile 0 to 1.9) and in the Multnomah Channel and did not find contaminants at levels of concern.
- EPA sampled sediments immediately downstream of the study area in the Willamette River and Multnomah Channel and found some low-level contamination. There was some evidence of contaminant migration from the study area for certain contaminants.
- EPA tested surface water and found these results, reported in the remedial investigation report (USEPA 2016a):
  - *“Concentrations of contaminants in surface water within the study area are generally higher than those measured in upstream samples under all flow conditions. Elevated concentrations were observed in both transect (cross-river composite samples) and single-point surface water samples at various locations throughout the study area. The highest contaminant concentrations in surface water within the Site were found near known sources. At the downstream end of the study area and Multnomah Channel, concentrations of total PCBs, dioxin/furans, DDX, bis(2-ethylhexyl) phthalate (BEHP), chlordanes, and aldrin in surface water are greater than concentrations entering the study area and indicate that contamination from Portland Harbor is being transported downstream to the Columbia River.”*

Based on this information, approximately 1 mile of the Willamette River along Sauvie Island has been identified as part of the Site due to unacceptable risks and is included in the selected remedy for MNR.

EPA’s selected remedy will remove contamination as effectively and efficiently as possible by targeting areas with the highest concentrations and risk with active remedial technologies in order to safeguard the communities along the Willamette, including those downstream of higher risk areas.

Regarding concerns about the quality of well water supplying drinking water to the Sauvie Island community, it may be likely that some of the Island’s private domestic wells are accessing the same groundwater aquifer. In such cases, test results from a nearby public water system may approximate what the water quality is in a private well. In addition, if a private well has been tested recently by its owner, the results could also approximate neighboring wells.

EPA suggests the community contact the Oregon Health Authority, which is the agency in charge of monitoring community well water supply compliance with drinking water quality regulations. The community can also access information about the water supplies regulated by Oregon Health Authority online at <https://yourwater.oregon.gov/>.

### 2.2.11 Address Enforcement Concerns

#### Comment Summary

Four comments were received that referenced enforcement issues. These included prevention of activities that might compromise the remedy, compliance with fish advisories, completion of existing

actions at upstream sites, PRP issues, and obligations of cleanup for newer small landowners next to or within the Site.

These comments include:

- “Cleaning up is only the start. I want to see ground breaking regulation on our river that prohibits emissions. This means strict regulation - a gatekeeper law - that requires all motorized vehicles traveling the river to be licensed and approved before travel or regulation. This will create jobs and will greatly improve the quality of our river water, thus improving the quality of life.”
- “Monitored recovery requires more than signage and fencing along the riverbed, but regular enforcement.”
- “Include ongoing pollution controls in the final cleanup plan, including from upriver sources. Do not allow re-contamination from upland sources. Use EPA enforcement authority to clean up major hot spots like Arkema, shut off upland pollution sources, and define an appropriate, diminished role for Oregon DEQ during the cleanup process.”
- “How are you going to get someone like that to maybe agree to pay any money toward the cleanup, and what happens when they say ‘I’m not going to, I want the state to take care of it, it’s their land technically and I want them to pay the bill?’”

### **EPA Response**

EPA will work with state and local regulatory agencies to promote public safety including, enforcement of permits and other regulatory pollution requirements and attempt to prevent activities that might compromise the remedy. EPA’s regulatory enforcement programs will continue to work with DEQ on coordinating inspections and enforcement activities as appropriate. Fish advisories themselves are not enforceable; however, EPA will continue to do outreach and education in the community regarding health risks from eating resident fish from the river. To minimize the potential for recontamination of capped/dredged areas, EPA will work with DEQ and use enforcement authorities, if needed, to address known and discovered upstream sources. EPA, state and local agencies will continue to identify and promote cleanup of sources as they are found, whenever feasible.

## **2.3 ARARs, PRGs, and COCs**

### **2.3.1 Applicable or Relevant and Appropriate Requirements Issues**

#### **Comment Summary**

Comments specific to ARARs were received from businesses, the Portland Audubon Society, and the City of Portland.

Summaries of those comments are:

- EPA is required to consider ARARs in selecting its preliminary remediation goals (PRGs). Generally, these will be validly promulgated laws or regulations of the state. EPA guidance provides that, when a state has considered federal criteria and adopted different, state-specific standards, the CERCLA process should follow the state standards. However, in this case, instead of giving due consideration to Oregon regulations, EPA appears to have made arbitrary choices to choose more stringent federal standards, without giving any weight at all to the state-specific factors that led Oregon to regulate in a different way (including with respect to Oregon standards

that EPA formally approved!). EPA should correct this in its ROD; in any case where EPA sets a Remediation Goal on the basis of an ARAR, that ARAR should be the applicable Oregon standard.

- If a state has promulgated a numerical [water quality standard, or “WQS”] that applies to the contaminant and the designated use of the surface water at a site, *“the WQS will generally be applicable or relevant and appropriate for determining cleanup levels, rather than [the NRWQC]. A WQS represents a determination by the state, based on the [NRWQC], of the level of contaminant which is protective in that surface water body, a determination subject to EPA approval.”* (Emphasis added.) 53 F.R. 51394, 51442 (Dec. 21, 1988, explanation of revisions to the National Contingency Plan).
- EPA’s proposed plan has chosen to ignore this aspect of Oregon’s beneficial use designation and has apparently decided instead that any groundwater discharging to the river needs to meet this standard at any sampling point within that groundwater, not taking into account either what the concentration would be in-stream or after conventional treatment, assuming the Lower Willamette River at Portland Harbor is ever used for drinking water (and there are no plans to do that).
- EPA should eliminate all groundwater PRGs because they are not needed to support the RAOs. EPA’s proposed plan designates a number of groundwater PRGs on the basis that they are “ARARs.” In many cases, these are based on Oregon’s surface water quality standards. However, Oregon’s water quality standards are clearly applicable to the waterbody itself, not to groundwater. Oregon would certainly take its water quality standards into account in determining whether a discharge of groundwater would impair the surface water body itself, by causing an exceedance of the water quality standard in the surface water, and any cleanup decisions made in Portland Harbor should follow that approach. However, the water quality standards are in no sense “ARARs” as applied to groundwater and should not be made “groundwater” remediation goals.
- To the extent EPA is adopting what it considers to be an Oregon-based ARAR, it can only do so after adjusting the ARAR value to account for what Oregon would determine to be natural background. OAR 340-122-0040 (1)(c).
- At complex sediment sites, it is not feasible to predict the course of cleanup efforts with great certainty or to foresee every possible change in circumstance. At many sites, EPA has therefore incorporated provisions into the ROD for technical impracticability waivers to allow EPA to adapt to circumstances or additional information. Such waivers are site-specific waivers for specific contaminants. EPA has expressly acknowledged that: “Technical impracticability waivers are one of the means of waiving ARARs consistent with CERCLA Section 121(b) and the NCP [Section 300.430(f)(1)(ii)(C)(3)]. Through analysis of site data and demonstration of the impracticability of achieving ARARs...a waiver may be appropriate.” *Summary of Technical Impracticability Waivers at National Priorities List Sites*, OSWER Directive 9230.24, August 2012, Washington, D.C.
- Per EPA sediment remediation guidance “RAOs should reflect objectives that are achievable from the site cleanup.” This leads to one of two possible EPA management decisions: (1) EPA should remove surface water RAOs from the 2016 draft final feasibility study report, given that site sediments are not the primary cause of surface water ARAR exceedances and therefore sediment remedies alone cannot achieve all of the most important chemical-specific ARARs in surface water; or (2) EPA should waive water quality ARARs for these same chemicals in the ROD. EPA

continues to maintain that, "Currently, EPA does not have a basis for waiving any ARARs. Any ARAR waivers would have to be conducted through the remedy selection process and documented in a ROD amendment." If EPA had correctly estimated alternative surface water concentrations (even using the simplistic approach attempted in Appendix K), or simply compared the upstream concentrations to EPA's proposed surface water PRGs, then it would have an obvious available basis for waiving many of the water quality-related ARARs. Instead EPA maintains that site sediment remedies might somehow achieve site surface water reductions below ARARs despite multiple other sources also contributing to those same ARAR exceedances. EPA supports this ongoing bias by conducting obviously flawed analyses, such as Appendix K, and ignoring upstream data and then contending there is no basis for waiving the surface water ARARs.

- The City of Portland requests that EPA provide an explanation of its "ARARs" and "TBC" selection process specifically regarding the following location-specific or action-specific state and local laws. The following laws have been considered ARARs at other cleanup sites in Oregon (for example the Zidell cleanup and the Teledyne Wah Chang Superfund Site). The City requests that EPA explain to the community how compliance with federal standards will protect our community to the same extent as these specific state and local laws:
  - State Historic Preservation Office laws ORS chapters 358 and 390
  - Fish Passage Laws ORS 509.580 through 509.910 which protect fish during and after remedy construction
  - Balanced cut and fill requirements of Portland City Code 24.50 which ensure flood resiliency
  - The Willamette River Greenway laws and Statewide Planning Goal 15, ORS 390.310 and the Greenway requirements promulgated by the City in Portland City Code 33.440 to comply with State law
  - Local noise ordinances that set maximum permissible sound levels and prohibit specific noise disturbances in Portland City Code 18.10 and 18.12
- The Audubon Society suggests that Alternative I fails to meet all ARARs. Specifically, it fails to meet or address the following:
  - State of Oregon Land Use Planning Goal 5 (natural resources), Goal 6 (Air, Water and Land Natural Resources Quality), Goal 7 (Natural Hazards) and Goal 15 (Willamette River Greenway)

### **EPA Response**

EPA disagrees with the comments that request that surface water and groundwater cleanup levels should be removed from the ROD. The human health and ecological risk assessments found that releases of hazardous substances found in surface water and groundwater within the Site pose unacceptable risks to humans from ingestion and bioaccumulation through the consumption of fish and to ecological receptors for direct contact, ingestion, and bioaccumulation through the consumption of prey. Therefore, having been triggered into action, development of RAOs and cleanup levels to achieve those RAOs for both media is appropriate at the Site.

CERCLA Sections 121(d)(1) and (2) require: “(1) that any remedial action selected shall attain a degree of cleanup of hazardous substances, pollutants, and contaminants released into the environment and control of further releases at a minimum which assures the protection of human health and the environment; and (2) any hazardous substance that will remain onsite, such remedial action shall require a level or standard of control which at least attains Maximum Contaminant Level Goals established under the SDWA, and water quality criteria established under Section 304 or 303 of the Clean Water Act, and any promulgated standard, requirement, criteria, or limitation under a State environmental or facility siting law that is more stringent than any Federal standard, requirement, criteria, or limitation that has been identified to the President by the State in a timely manner and is legally applicable to the hazardous substance or pollutant or contaminant concerned or is relevant and appropriate under the circumstances of the release or threatened release of such hazardous substance or pollutant or contaminant.” 42 U.S.C. § 9621(d)(1) and (2)(A)(i) and (ii).

The NCP provides that “[r]emediation goals shall establish acceptable exposure levels that are protective of human health and the environment and shall be developed by considering the following: [A] [ARARs] . . . [B] . . . [MCLGs] . . . [E] Water quality criteria established under sections 303 and 304 of the Clean Water Act . . .” 40 CFR § 300.430(e)(2)((i)(A), (B), and (E). As noted in the preamble to the NCP: “As new information and data are collected during the remedial investigation, including the baseline risk assessment, and as additional ARARs are identified during the RI, these preliminary remediation goals may be modified as appropriate to ensure that remedies comply with CERCLA’s mandate to be protective of human health and the environment and comply with ARARs.” See 55 Fed. Reg. 8712, May 8, 1990.

Likewise, to be protective of human health and the environment, remediation levels for some substances may have to be based on non-promulgated criteria and advisories rather than on ARARs, because ARARs do not exist for those substances or because an ARAR alone would not be sufficiently protective in the site-specific circumstances, e.g., where additive effects from several chemicals are involved. Similarly, state criteria, advisories, and guidance should also be considered for the state in which a site is located.

EPA followed the requirements of CERCLA and the NCP and developed preliminary remediation goals, which are now the final cleanup levels in the ROD for surface water and groundwater by looking to federal and state ARARs, including Section 304(a) criteria, state promulgated water quality criteria, (MCLs) and MCL goals (MCLGs). If there was no ARAR, such as for manganese (a groundwater COC), the Regional Screening Level was selected. The cleanup levels based on chemical-specific ARARs for surface water and groundwater are considered protective of human and ecological receptors exposed to the COCs and consistent with the site-specific risk assessments. EPA is required under the NCP at 40 CFR 300.430(e)(2)(i) as previously indicated to consider ARARs to define the PRGs when they set an acceptable level with respect to site-specific factors.

Consistent with CERCLA, the cleanup levels for RAO 3 (surface water/human health) and RAO 4 (groundwater/human health) are based on the lower of the federal National Recommended Water Quality Criteria established under Section 304(a) of the Clean Water Act, Oregon water quality standards, MCLs, and non-zero MCLGs, as presented in Table 2.1-4 of the feasibility study report. On stringency, the NCP preamble notes: *CERCLA requires that remedial actions comply with all requirements that are applicable or relevant and appropriate. Therefore, a remedial action has to comply with the most stringent [emphasis added] requirement that is ARAR to ensure that all ARARs are attained. In addition, CERCLA requires that the remedies selected be protective of human health and the environment and attain ARARs. A requirement does not have to be determined to be necessary to be protective in order to be an*

*ARAR. Conversely, the degree of stringency of a requirement is not relevant to the determination of whether it is an ARAR at a site and must be attained (except for state ARARs). (See 55 FR 87841, May 8, 1990.)*

As previously indicated, CERCLA 121(d)(1) requires that the remedial action attain a degree of cleanup and control of further releases at a minimum which assures the protection of human health and the environment, contrary to comments that only state standards should be applied, EPA was justified in using the more stringent criteria identified above in lieu of the State of Oregon WQS for COCs in media that relate to unacceptable risks identified in the risk assessments to actual or potential receptors as represented in the RAOs. In some cases, cleanup levels established for COCs in groundwater for ecological receptors in pore water appear to be the federal National Recommended Water Quality Criteria established under Section 304(a) of the Clean Water Act; however, the baseline risk assessment established these groundwater cleanup levels as protective levels for acceptable risk. Thus, EPA has not applied a surface water criterion to groundwater but rather used a risk-based level protective of receptors as defined by the risk assessment to achieve an RAO.

EPA's use of Safe Drinking Water Act MCLs as cleanup levels for COCs in surface water or groundwater is appropriate at the Site and EPA did not ignore Oregon's beneficial use designation, but in fact is protecting the beneficial uses of both groundwater and surface water by applying the SDWA standards. CERCLA and the NCP are clear that MCLs are to be achieved in contaminated groundwater and surface water at a site when relevant and appropriate under the circumstances of the release. MCLs are relevant and appropriate under the circumstances of the release at Portland Harbor because the designated uses of the lower Willamette River include drinking water supply. (Designated Uses for the Willamette Basin specified for the Willamette Basin at OAR 340-041-340 and 340-041-0345.) Likewise, all ground water of the state, including the ground water adjacent to and under the lower Willamette River, are to be protected for the beneficial use of domestic drinking water supply. OAR 340-040-0020(3), which is as stringent or more stringent than the *EPA Guidelines for Ground-Water Classification* (USEPA 1986) (See 55 FR 8732, March 9, 1990). Releases of hazardous substances have occurred to groundwater that is discharging to or under the river within the Site or has the potential to discharge to the river, which exceed relevant and appropriate Safe Drinking Water Act standards for groundwater and surface water cleanup. As noted in the 1991 Role of the Baseline Risk Assessment guidance, exceedances of MCLs and water quality criteria may warrant action under CERCLA. Therefore, it is appropriate for the final selected remedy to set cleanup levels based on MCLs for groundwater and surface water at the Site. Furthermore, CERCLA guidance is clear that where either surface water or groundwater is or may be used for drinking water, MCLs are relevant and appropriate as cleanup standards. Thus, the notation in State of Oregon regulations by the commenters concerning pretreatment requirements is not a limitation on the use of MCLs at the Site. Likewise, under the circumstances at this Site, both groundwater and surface water are potential drinking water resources, and discharges of contaminants to the river represent one continuous pathway. Therefore, there is no basis to distinguish pore water from groundwater or surface water in regard to where compliance with the ARAR should be met. See Response 2.4.3 and EPA's response to LWG Dispute Issue 1m for further response to the legal bases and site-specific reasons why MCLs are relevant and appropriate to releases at the Site and Oregon's designated use regulation is not inconsistent with their use at the Site.

Regarding comments that EPA's cleanup levels should be adjusted for natural background levels in accordance with Oregon Administrative Rules 340-122-0040(1)(c), first that regulation doesn't exist as cited therefore, EPA assumes that the commenter meant Oregon Administrative Rules 340-122-

0040(2)(c). That regulation states: “(2) In the event of a release of a hazardous substance, remedial actions shall be implemented to achieve: . . .

*(c) For areas where hazardous substances occur naturally, the background level of the hazardous substances, if higher than those levels specified in subsections (2)(a) through (2)(b) of this rule.”*

EPA’s final cleanup levels for the Site, do not conflict with this provision. No cleanup level has been identified by DEQ that is below natural background levels as calculated by DEQ. Also, it is EPA policy to not cleanup beyond natural and anthropogenic background levels. No such background levels have been established for COCs in groundwater and surface water at the Site.

Likewise, EPA does not agree that surface water and groundwater cleanup levels based on ARARs are unachievable, and they should be waived. There has been no information or analysis provided to EPA to date that supports a waiver of any water standard or MCL at this Site. It is EPA’s expectation that DEQ’s upland source control actions will adequately address groundwater contamination discharging to the river (the plumes) and will protect surface water quality. RAOs for groundwater are focused on containing and reducing migration of COCs from groundwater to surface water and biologically active areas of sediment. Should groundwater not be addressed adequately under DEQ’s actions, RAOs for surface water are addressing the risks that COCs in surface water are presenting to human health and the environment. EPA may, at a future time, determine if action is warranted under CERCLA to further address groundwater or surface water contamination. Likewise, if during remedy implementation it is discovered and demonstrated that achieving water quality standards or MCLs in a reasonable timeframe is not technically practicable a waiver for specific COCs that are not achievable for a particular area or areas could be considered. It should be noted that under EPA policy and guidance, a waiver requires significant efforts pre- or post-remedy implementation to document that it is not technical practicable to achieve an ARAR.

EPA has considered the City of Portland codes indicated by commenters as being omissions from the identified ARARs. Neither CERCLA 121(d) nor the NCP requires CERCLA actions to comply with local laws; i.e. local laws in themselves are not ARARs. EPA has determined the suggested requirements are not ARARs for the selected remedy because they are local laws and not otherwise applicable or enforceable state-wide.

EPA has also considered the Oregon Revised Statutes indicated by commenters as being omissions from the identified ARARs. It should be noted that State Historic Preservation Office laws (Oregon Revised Statutes chapters 358 and 390) that were incorrectly indicated by commenters as being omitted as ARARs were in fact identified by DEQ as potential ARARs to EPA and thus are included as ARARs in the ROD.

With respect to state land use goals and Oregon Revised Statutes 390.310 and 509.580 through 509.910 is that for State requirements to be considered as ARARs under CERCLA, the NCP (specifically at 40 CFR 300.430(d)(3)) requires that the support agency (State of Oregon) identify potential ARARs in a timely manner for consideration. EPA worked closely with DEQ during the ARARs identification process and the requirements cited by commenters were not identified by DEQ as potential ARARs. However, numerous federal and state laws for fish and wildlife coordination and endangered species identified as ARARs can address the concerns about fish passage.

For additional information, please also see LWG Dispute Issue 1g, 1m, 1n, 1o, and 1s (Appendix A of this document) and Sections 2.4.3 and 2.4.4 of this responsiveness summary.

### 2.3.2 Make Unlimited Fish Consumption for All Groups a Cleanup Level and RAO

#### Comment Summary

This was the most commonly seen comment and almost 3,000 comments were received that stated that the cleanup should result in fish being safe to eat, without restrictions, for any population. About 90 percent of comments received were received as form emails or preprinted postcards that listed a variety of other comments.

Representative comments of this type included:

- “I urge EPA to implement a plan that: Contributes to healthy fish that are safe to eat for all people.”
- “The goal of the cleanup must be to end the Fish Consumption Advisory related to pollutants found in the Portland Harbor stretch of the Willamette River for all people. EPA should provide a date by which the advisory will be lifted.”
- “The Cleanup Plan must result in removal of Fish Consumption Advisory so that eating fish from the Lower Willamette is just as safe as eating fish from anywhere else in the Willamette River System and this must occur within a 10 to 20-year time frame.”
- “EPA should select an alternative that allows all members of our community to eat fish safely from our river, including woman of childbearing age and children.”
- “The overall goal of the Superfund cleanup should be to lift the fish consumption advisory for ALL people (including breast feeding women) related to the toxic pollutants found in the Portland Harbor area of the Willamette River.”
- “I ask EPA to create a plan that leads to healthy fish that are safe to eat.”
- “The overall goal of the Superfund cleanup should be to lift the fish advisory related to toxic pollutants found in the Portland Harbor area of the Willamette River.”
- “The final result of the cleanup should be the lifting of the Fish Consumption Advisory related to PCBs for the Portland Harbor area by a specific date.”

The remaining 248 comments were received as personal emails, letters, or postcards. Representative comments of this type included:

- “The plan does not go far enough to protect public health concerning the consumption of fish. It is in the public’s interest that the river is cleaned up to an extent where advisory warnings can be lifted, and that everyone, including infants and women of child bearing age, can eat local fish. I’m afraid that the CERCLA-based fish advisory program will not sufficiently protect the public, and I advise that the health of the fish that is to be consumed be verified according to the Oregon Health Authority.”
- “Many of us in Portland grow some of our own food and are committed to buying local as much as possible. Having access to free, fresh and NON-TOXIC fish is part of that commitment. The plan for sustainable cleanup of the river must include a TIMELINE for WHEN NON-TOXIC FISH caught in our own rivers could be consumed, especially by pregnant women and young children.”

- At the very least the fish consumption advisory needs to be lifted at the end of the cleanup. Help ensure that this Osprey can fish for clean fish, and people can consume fish without increased cancer risk!! I'd sure like to know what fish I do eat from the Willamette isn't a threat to my health or that of my family and friends. I know there are lots of people who use this river and its tributaries for fish to supplement their diets and they are living hand to mouth in this economy. Let's do the right thing and clean up this river. It's a black mark on the city of Portland and the PNW which prides itself on being eco and clean!"
- "Communities who fish the river for sport, support, or tradition can safely eat only a limited amount of their catch (8 oz. per person per month), while children, the elderly, nursing & pregnant mothers and others at risk are prohibited from eating any fish caught in the area. People who depend on Willamette River fish for dietary protein have increased cancer risk."
- "Navigable rivers belong to all of us. If I dumped poison in the river, I would be held responsible. We'll know the river is clean enough when the Fish Consumption Advisory can be lifted, and we need to know when that can be reasonably expected to happen."
- "Some people rely on the river for their subsistence. Now, they regularly exceed the Oregon Health Authority's recommendation of eating more than 8 oz PER MONTH even though it could be deleterious to their health because they can't afford healthier choices. EPA MUST set a certain date and measurements so fish from the Willamette are safe to eat again!"
- "As the most vulnerable members of our community eat fish from the Willamette, it is also important for the plan to provide a firm date when the Fish Consumption Advisory will be lifted and hold those liable responsible for hitting that date, with risk of meaningful fines. Fish should be regularly tested for contaminants to ensure that the Advisory will be lifted on time."

### **EPA Response**

Within the Site, persistent contaminants (particularly PCBs, chlorinated pesticides such as dichlorodiphenyltrichloroethane [DDT], and polychlorinated dioxin and furans) from sediments and surface water bioaccumulate in the food chain, resulting in higher concentrations of the contaminants in fish tissue than in sediments. Existing Oregon Health Authority fish consumption advisories apply to all resident fish at the Site, including carp, bass, and catfish, advising none of these fish be consumed by children under age 6, women of childbearing age, and people with thyroid or immune system problems and no more than 1 fish meal per month for everyone else. There is no advisory for consumption of migratory salmon because these fish do not reside at the Site long enough to bioaccumulate the contaminants in their tissue to levels of concern as determined by Oregon Health Authority. Fish advisories once cleanup has achieved its goals, though less restrictive in the future, may need to remain due to broader watershed issues.

EPA's risk assessment process evaluates cancer and non-cancer risks based on a reasonable maximum exposure that could occur at the Site, and it is reasonable to look at a subsistence level of fish consumption at this Site given the reserved tribal treaty rights and known amount of fishing that immigrant communities in Portland do.

During implementation of EPA's selected remedy, fish could be exposed to increased levels of contaminants from sediments being disturbed by dredging and capping activities. During construction, people would be advised to eat no more than 0.6 fish meals per year or 4.8 ounces per year (considering

an 8-ounce fish meal) for most populations and 0.1 fish meals (8 ounces per year) for women who may breastfeed. This advisory would be in place for the 13 years of construction of the selected remedy.

After all active remediation being proposed for the selected remedy is completed, EPA estimates that the temporary construction fish advisory would be relaxed to allow for 16 fish meals every year to be safely consumed from the Site for most populations at completion of construction and 1 fish meal per year for women who may breastfeed.

The selected remedy addresses all risk to ecological receptors from eating fish and will result in substantial risk reduction for human fish consumers, but it likely will not be possible to reduce the concentrations of PCBs and other contaminants to levels low enough to allow for consumption at the higher consumption rates associated with subsistence fishing. Upstream of the Site, background levels of PCBs from “clean” areas exceed the acceptable range based on conservative risk estimates. Therefore, fish advisories would remain in effect following the cleanup but would be less restrictive because the highest concentrations of bioaccumulative contaminants in sediment would be removed or capped such that they no longer enter the food chain within the Site. Watershed-wide implementation of source reductions through water quality programs by the DEQ in conjunction with source control activities at the Site are expected to contribute to the elimination of fish consumption advisories over time. Fish advisories due to contamination at the Site would be modified based on the results of long-term monitoring of contaminants in fish tissue and fish tissue surrogates (like passive monitoring where necessary). Although CERCLA-related fish advisories would remain in place until final cleanup levels are achieved, Oregon Health Authority may still impose an advisory based on broader watershed risks. Because these contaminants can pose risks even when the concentrations in the environment appear quite low, it is critically important to remove these persistent pollutants from the environment.

### 2.3.3 Acknowledge that Safe Fish Consumption at All Levels Is Not Supportable

#### Comment Summary

One commenter wrote that the goal of unlimited fish consumption was at odds with federal guidance from other agencies. Specifically:

- “EPA’s water quality goal for the Willamette is that a person could eat fish from the river as their main source of food for twenty years without any ill effects. This might be a good goal, but it is an extremely unrealistic one for an urban river. Not only that, but such a diet would far exceed what another branch of the government, the FDA, safely recommends. The standard that EPA has set is impossible to reach.”

Two other commenters spoke to concentrations of mercury in fish that are not related to the Superfund issues at the Site:

- “The WWC struggles with the expectation that the targeted cleanup levels can actually be achieved in an urban waterway. EPA uses remediation levels that do not adequately consider sources of contaminants coming into the system, from upstream of Portland Harbor. After cleanup, fish advisories will remain in the Lower Willamette, given the ongoing need for mercury advisories that are established by the Oregon Health Authority and unrelated to sources within the Harbor.”
- “None of the cleanup alternatives evaluated by EPA will allow all fish advisories to be lifted since none will lower the risk posed by the background mercury content of resident fish at the Site.

Mercury impacts are watershed-wide and cannot be addressed by any remedy performed at the Site. To date, EPA has done little to challenge the public misperception that remediation of the Site will allow all fish advisories to be lifted.”

### **EPA Response**

EPA’s mandate under CERCLA is to select remedies that are protective of human health and the environment. EPA generally will not require cleanup beyond background levels of contamination and is not doing so in the selected remedy. One of the designated uses for the Willamette River is fishing, and EPA does not consider other health issues that might exist around such use in making its remedy decisions. Fish consumption advisories will be less restrictive once the cleanup has been completed. However, fish consumption advisories likely will not be lifted completely due to larger watershed issues (such as mercury) and because concentrations of PCBs upstream of Portland Harbor are higher than the acceptable range based on conservative risk estimates, and sediments naturally move downstream. Over time, it is expected that source control actions on the part of DEQ in Portland Harbor and watershed-wide (including upstream areas) will reduce the need for stringent fish consumption advisories. We are uncertain how other actions in the river may over time contribute to reducing fish advisories further in the future.

Contrary to some of the commenters’ view, EPA has been very transparent about the fish advisories and what benefit the cleanup would have and what was beyond the control of the CERCLA cleanup. The feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c) communicated what background levels existed and that watershed issues likely would lead to some fish advisory staying in place even after the remedy’s cleanup goals were achieved.

### **2.3.4 Don’t Select PRGs that Are Unattainable**

#### **Comment Summary**

Many commenters stated that the PRGs presented in the feasibility study and proposed plan for the Portland Harbor Site were unattainable due to background concentrations. It was stated that many of the COCs identified for the Portland Harbor Site are ubiquitous in the environment and associated with a broad range of urban and agricultural sources and the PRGs are set below background. In particular, many commenters stated that the proposed PRG for PCBs in sediments of 9 micrograms per kilogram ( $\mu\text{g}/\text{kg}$ ) was below the “equilibrium” concentration of 20  $\mu\text{g}/\text{kg}$  as determined by the Lower Willamette Group. In addition, sediment PRG for DDx should be no lower than 5  $\mu\text{g}/\text{kg}$ , and an equilibrium-based PRG for dioxin/furan should be developed during remedial design. It was also noted that the proposed PCB fish tissue goal of 0.25  $\mu\text{g}/\text{kg}$  PCBs is lower than the 23  $\mu\text{g}/\text{kg}$  PCB concentration EPA predicts based on its background concentration of 9  $\mu\text{g}/\text{kg}$ .

One commenter stated that consideration of background is important because PRGs need to be attainable, and some of the risk-based PRG concentrations are less than the naturally occurring or anthropogenic background concentrations, meaning that PRGs may not be attained. If remediation goals are not reached, the cleanup and associated monitoring could continue in perpetuity. The commenter noted that it is common at cleanup Sites to require parties to achieve background concentrations as the remedial goal when there are known upstream sources. However, in the case of Portland Harbor, EPA has not used upstream background concentrations to set achievable remediation goals for surface water or tissue and has not used background concentrations that appropriately characterize chemicals coming into the Site for sediment PRGs. Comments say that EPA’s remedy must use a realistic and appropriate set of cleanup levels that consider background, site equilibrium, and risk management. In establishing

unattainable PRGs, the proposed plan is setting unrealistic expectations for the public and discouraging the willing performance of cleanup activities.

One commenter advised EPA to not select risk-based PRGs below equilibrium values. In the dispute decision by Rick Albright, he stated that “there are sources of contamination outside of the Site – both upriver and within the downtown reach – that may affect the ability of the cleanup efforts within the Site to equilibrate to the selected cleanup level regardless of whether the cleanup level is based on risk, regulatory standard or background.” The commenter advised EPA to not select risk-based PRGs below equilibrium values and stated that “EPA’s failure to base its cleanup number on equilibrium are inconsistent with the reasoning of its own former director and an array of real world data and undermine the presumption that EPA’s proposed cleanup goal for PCBs is realistically achievable.”

One commenter (USACE) stated that chemical sediment data from 17 dredging projects within the Lower Willamette River indicates that EPA’s PRGs are unattainable for most, if not all, projects within the Lower Willamette River outside sediment management areas (SMAs). Specific PRGs that are excessively low include arsenic, mercury, Dieldrin, hexachlorobenzene, carcinogenic PAHs (cPAHs), DDX, PCBs, and all dioxin/furan congeners. Figures 1.2-6a/b to 1.2-18a/b in the feasibility study report show that chemical concentrations exceed the proposed PRGs throughout the non-cleanup portions of the Harbor and thus demonstrate that EPA’s PRGs are unattainable.

### **EPA Response**

Consistent with EPA guidance and policy, background concentrations may be used to develop cleanup levels when risk-based PRG concentrations are less than naturally occurring or anthropogenic background. The derivation of background concentrations in sediment for the Site is described in Section 7 of the remedial investigation report (USEPA 2016a). Background concentrations for dioxin/furan congeners were not calculated in the remedial investigation report but were for the feasibility study report (USEPA 2016b) and are provided in Section 2 of Appendix B of that document.

Background sediment concentrations were based on sediment data collected upstream of the Site between RM 15.3 to 28.4. This area, which extends from the upstream end of Ross Island (just upstream of the downtown Portland area) to approximately 2.5 miles above Willamette Falls, was chosen because it is considered broadly representative of the upstream sediment loading to Portland Harbor and not generally impacted by sources within the Site. Background concentrations as represented by the deposited sediment concentrations within this reach remain the best predictor of achievable cleanup goals for the Site. Sediment data collected from the downtown reach were not utilized for the development of background levels due to sources in this reach being actively addressed by DEQ. Background sediment concentrations were used as PRGs for all COCs for which the risk-based PRG was less than background. Background concentrations were not established for surface water, groundwater or biota tissue due to the insufficient sample size associated with these media. Development of background levels for other media may be considered during pre-remedial design characterization.

The Lower Willamette Group (LWG) developed equilibrium estimates based on upper confidence limits (UCLs) on a central tendency (median) of the empirical sediment lines of evidence (deposited surface sediment data, sediment traps, and suspended sediments). EPA selected a background-based PRG for PCBs based on a statistical evaluation of bedded sediments upriver of Portland Harbor. It should be noted that the sediment data for Portland Harbor are replete with a large signature of PCB concentrations at or less than the PRG of 9 µg/kg, which would not be possible if LWG’s “equilibrium” theory were credible. It should be noted that EPA’s determination of background was the subject of a

formal dispute by LWG and resulted in a March 24, 2015 dispute decision by EPA's Director of the Office of Environmental Cleanup. The dispute official concluded that EPA's methodology for establishing background concentrations for COCs at the Site was consistent with EPA guidance and followed the correct statistical procedures and thus, is appropriate for establishing background-based PRGs for the Site. EPA acknowledges that there are sources of contamination outside of the Site – both upriver and within the downtown reach – that may affect the ability of the cleanup efforts within the Site to equilibrate to the selected cleanup level regardless of whether the cleanup level is based on risk, regulatory standard or background. However, no new information has been provided in the public comments that would lead EPA to reach a different conclusion on the background methodology and the data that were taken.

EPA disagrees that achievement of background based PRGs and now final cleanup levels, is unattainable. As is noted above, many areas of the Site have PCB concentrations at or less than the PRG of 9 µg/kg. For more discussion on background PRGs and issues surrounding them, see Dispute Responses (Appendix A of this document) [AR Doc #500011627]. This demonstrates that active remediation through capping and dredging in conjunction with monitored natural recovery has the potential to achieve the background based PCB PRG of 9 µg/kg.

### 2.3.5 Address PRG Issues with Risk Management or Risk Assessment

#### Comment Summary

Commenters stated that EPA failed to incorporate risk management into the development of PRGs as evidenced by the large number of PRGs developed for the Site. It was noted that EPA has proposed that the remedial action be designed to achieve 107 different PRGs for 64 different chemicals. The commenters stated this number of PRGs is high in comparison to other major sediment sites such as the Lower Duwamish Waterway, Fox River, Lower Passaic River, and Grasse River sites. The commenters stated that EPA should exercise risk management to shorten the list.

Many commenters also stated that the PRG list is inconsistent with the conclusions of the human health and ecological assessments. It was specifically noted that PRGs should be developed only for COCs identified in the risk assessment. It was further stated that PRGs should only address potential risk for contaminants, media and pathways that were clearly found to pose unacceptable risks in the baseline risk assessments and should focus on the subset of unacceptable risks that are required for selecting an effective and protective remedy using all of the feasibility study criteria. Specifically, EPA should include in the feasibility study only those COCs and PRGs that meet the following requirements:

- For contaminant/exposure scenarios pairs that show unacceptable risk from in-river media
- Calculated with EPA approved baseline risk assessments methods
- Where there is scientifically valid information to calculate those PRGs
- That are technically practicable to achieve
- That reflect a reasonable risk management framework
- Can be attained through sediment remediation which would exclude surface water PRGs
- Can be applied to matrices that can be directly addressed through sediment remediation which would exclude fish tissue PRGs

One commenter stated that PRGs should be adjusted to reflect EPA's risk range based on its own risk management guidance. The commenter stated that EPA should set the target risk between  $1 \times 10^{-5}$  and  $1 \times 10^{-4}$ . Another commenter questioned how the PRGs were applied, stating that neither the recreational beach user nor the tribal fisher exposure scenario should be applied to establish a site-wide cPAH PRG because much of the Portland Harbor is designated for industrial use and public access is limited. The commenter also stated that EPA's site-wide application of a single PRG for both river bank soils and river sediments is inconsistent with its own guidance, which requires characterization of the exposure setting "with respect to the generally physical characteristics of the populations on and near the Site" and the baseline human health risk assessments, which evaluated recreational beach exposures only for specific areas and that a recreational beach exposure scenario is not likely for the majority of the Site given the industrial nature of the Site, which limits access. Finally, the commenter stated that EPA should use the approach utilized for the Lower Duwamish Waterway, which established different cPAH cleanup levels for different areas of the Site based on land use and exposure scenarios.

One commenter noted that EPA has established focused COCs that pose the greatest risk to human health and the environment and questioned why there are PRGs for the other 64 COCs that already have regional thresholds that are used in the PNW and have no RALs in the feasibility study and proposed plan.

### **EPA Response**

As described in Section 2.2.2 of the feasibility study report (USEPA 2016b), PRGs were developed to address unacceptable human health and ecological risks identified in the baseline human health risk assessment (BHHRA) (Kennedy/Jenks Consultants [Kennedy/Jenks] 2013) and baseline environmental risk assessment (BERA) (Windward 2013) consistent with the NCP which states that "remediation goals shall establish acceptable exposure levels that are protective of human health and the environment" 40 CFR §300.430(4)(e)(2)(i). The baseline risk assessments determined that contaminated sediments and surface water presented unacceptable risk to human health and the environment. Transition zone water was found to exceed MCLs for drinking water exposures and posed unacceptable risk to ecological receptors.

Regarding the number of COCs and PRGs, it should be noted that the Portland Harbor Site has numerous sources of contamination from a wide range of industries. Thus, while the use of focused COCs for the purpose of conducting evaluations in the feasibility study is considered appropriate because the remedial footprint of the focused COCs encompasses the majority of the COCs at the Site, the large number and diverse nature of sources and contamination presenting unacceptable risk at the Site necessitate the identification of a relatively large number of COCs in multiple media to be addressed by the response action. This comprehensive set of COCs and PRGs will ensure that EPA's remedy addresses all of the risk to human health and the environment at the Site, and are monitored for subsequent five year reviews, and addressed through source control actions.

For human health, risk-based sediment PRGs were calculated using reasonable maximum exposures for the most susceptible population evaluated in the BHHRA consistent with the NCP. For human health, PRGs were calculated based on direct contact with beach and in-river sediment (remedial action objective [RAO] 1) and consumption of fish and shellfish (RAO 2). MCLs, EPA tapwater screening levels, state water quality standards and national recommended water quality criteria were used to set PRGs for RAOs 3 and 4. For ecological risk, risk-based PRGs were developed from medium- and contaminant-

specific toxicity reference values protective of ecological receptors and used in the BERA. The specific methods used to develop PRGs are described in Appendix B of the feasibility study report.

EPA disagrees that the PRGs and now the final cleanup levels are inconsistent with the baseline human health and ecological risk assessments. Action is warranted based on unacceptable risk to human health and ecological receptors due to the presence of a variety of contaminants at the Site. Risk-based human health COCs were identified in beach and in-water sediment, fish tissue and surface water. Risk-based ecological COCs were identified in sediment, surface water, pore water, and river bank soil. As described in Appendix B of the feasibility study report, PRGs were then calculated for all contaminants that posed an excess lifetime cancer risk greater than  $1 \times 10^{-6}$  or a hazard quotient greater than 1 in the final Portland Harbor BHHRA assuming reasonable maximum exposure. For cancer effects, risk-based sediment PRGs were calculated as the concentration consistent with a specified target excess cancer risk of  $1 \times 10^{-6}$ . For non-cancer effects, the risk-based PRGs were the calculated concentration that would result in a specified target hazard quotient of 1. For both cancer and non-cancer effects, the sediment PRGs are calculated based on specified exposure pathways and receptors. Detailed equations that describe the PRG calculation methods are also presented in Appendix B.

Although EPA considered a range of PRGs that reflect EPA's risk range of  $1 \times 10^{-4}$  to  $1 \times 10^{-6}$  (see tables B3-4 and B3-5 of the feasibility study report), it should be noted that the State of Oregon regulations (OAR 340-122-0115[2] – Individual carcinogens – and OAR 340-122-0115[3] – cumulative risk from multiple carcinogens) require cleanups to achieve a  $1 \times 10^{-6}$  risk level for individual chemicals and a cumulative risk level of  $1 \times 10^{-5}$ . As a result, it is appropriate to select PRGs based on a  $1 \times 10^{-6}$  risk level and a hazard index of 1.

Regarding application of the site-use factor, see response to LWG Dispute Issue 1d (Appendix A of this document) which states in part "When potential exposure at more than a single area is considered likely, use of a site-use factor is no longer protective." Also, see response to LWG Dispute Issue 1j (Appendix A of this document).

EPA disagrees with the commenter that it is inappropriate to set a site-wide cleanup for the recreational beach user or the tribal fisher exposure scenario because much of the Site is designated for industrial use and public access is limited. Tribal fishers currently use the river, there are several beach areas accessible by people beyond designated public beaches, and land and waterway use is dynamic and may change in the future. Furthermore, some fish species are migratory, and in many cases, there is water access to the stream for recreational uses. As result it is appropriate to establish PRGs based on recreational and tribal fishing exposures throughout the Site.

### 2.3.6 Develop Technically Sound PRGs for cPAHs in Sediment

#### Comment Summary

It was noted that EPA has been unable to develop a technically sound cPAH sediment PRG for fish consumption due to the lack of a relationship between tissue and sediment. As a result, EPA assigned a shellfish consumption PRG to the navigation channel as a surrogate for fish consumption even though no shellfish harvesting can occur in the navigation channel. In addition, EPA inappropriately converted cPAH PRG to total PAH PRG based on irrelevant correlation calculation.

#### EPA Response

EPA agrees that it was not possible to develop a reliable cPAH sediment PRG for the fish consumption pathway due to the lack of a relationship between tissue and sediment. However, it was possible to

develop a sediment PRG for cPAHs based on the relationship between sediment and clam tissue. Contrary to the comment, the PRG was developed for cPAHs as benzo(a)pyrene equivalents (BaPEq). The relationship between cPAHs and total PAHs was used for the development of RALs. EPA also disagrees that the shellfish consumption pathway is not complete for the navigation channel. The commenter has not provided any information to support this statement, and there is no prohibition on collecting shellfish from within the navigation channel.

Regarding the development of different cPAH cleanup levels for different areas of the Site based on land use and exposure scenarios, EPA notes that the direct contact cPAH PRG is only applicable to nearshore areas. For other exposure pathways, such as shellfish consumption and exposure to the benthic community, exposure may occur throughout the Site, including nearshore areas and the navigation channel. Regarding consideration of bioavailability of PAHs in developing cleanup levels, EPA notes that studies of bioavailability were not conducted at the Portland Harbor Site and that, as stated in the response to comments on the benthic risk approach, site-specific toxicity testing may be where benthic risk cleanup levels are the only cleanup levels yet to be achieved.

### 2.3.7 Establish Fish Tissue Targets

#### Comment Summary

Some commenters stated that rather than establishing PRGs for other media in addition to sediment, EPA should follow the lead of the Lower Duwamish Waterway which established target levels for fish tissue and surface water to measure progress toward achieving RAOs and assessing the success of the selected remedy in conjunction with source control. In this EPA made it clear that the target levels were not cleanup levels and were to be used for informational purposes only. Other commenters stated that there should not be a fish tissue PRG or monitoring level for any chemical where there is no relationship between sediment and tissue.

#### EPA Response

PRGs were developed for fish and shellfish tissue because tissue concentrations represent a direct exposure point for human receptors and because tissue concentrations are needed to derive sediment PRGs for protection of human health due to fish consumption. However, based on public comments and upon reconsideration, EPA has determined that remedial levels for fish and shellfish tissue will not be enforceable cleanup levels. The selected remedy provides fish and shellfish tissue target concentrations to measure progress towards achieving RAOs 2 and 6, inform fish advisories, evaluate construction impacts, and update best management practices (BMPs) and institutional controls (ICs) as needed. Fish tissue levels are needed to evaluate the protectiveness of the remedial actions. Target tissue levels are not cleanup levels; rather they will be used for informational purposes to assess ongoing risks to people who may consume resident fish and shellfish. For protectiveness purposes, the fish tissue levels need to be achieved. If the fish tissue targets are not achieved, EPA expects to re-evaluate the remedy and determine what else may be needed. Tissue monitoring data will also inform the content and degree of any potential future fish advisories, and other ICs intended to minimize risk to recreational and subsistence fishers that may be identified in a ROD Amendment or explanation of significant differences.

### 2.3.8 Address Issues with the PRG for TPH Diesel for RAO 8

#### Comment Summary

Comments were received from three entities regarding the PRG for total petroleum hydrocarbon (TPH) diesel for RAO 8. That PRG is presented in Table 2.2-11 of the feasibility study report (USEPA 2016b) and is based on toxicity threshold concentration for the C10-C12 aliphatic hydrocarbon fraction and

because the C10–C12 fraction is a small subset of hydrocarbons present in the broader TPH-d fraction, a remedial cleanup level for TPH-d based solely on the toxicity of C10–C 12 aliphatic fraction it is not appropriate for groundwater or pore water.

One comment noted that the PRG for TPH-diesel in groundwater and pore water is neither supported in the administrative record nor technically defensible and should be eliminated. Another noted the analytical methods used to quantify aliphatic and aromatic hydrocarbons within the range of C5–C12 for VPH and C8–C34 for EPH have method detection limits above the C10 - C12 aliphatic hydrocarbon PRG of 2.6 micrograms per liter.

### EPA Response

As described in Section 2.2.2.2 of the feasibility study report (USEPA 2016b), water toxicity reference values from Attachment 10, Table 2 in the BERA (Windward 2013) that are protective of ecological receptors were selected as risk-based PRGs for RAOs 7 and 8. This includes the PRGs for petroleum hydrocarbons.

In the BERA, EPA provided toxicity reference values for five of the chemical groups that are blended to form gasoline. Because these fractions were not quantified in Study Area samples, the average fraction of these components in gasoline was used to convert the total gasoline-range hydrocarbon concentration into gasoline fraction concentrations for comparison with the toxicity reference values. The BERA further notes that gasoline components were used as a surrogate for gasoline-range hydrocarbons. Each component is counted as an individual COPC in the COPC count determination. A summary of the PRGs for each fraction is summarized in the table below.

TPH Fraction	Toxicity reference values (micrograms per liter)
Gasoline-range hydrocarbons	No Value
Aliphatic hydrocarbons C4-C6	128
Aliphatic hydrocarbons C6-C8	54
Aliphatic hydrocarbons C8-C10	9.5
Aliphatic hydrocarbons C10-C12	2.6
Aromatic hydrocarbons C8-C10	212

Due to the detections of TPH diesel in groundwater and pore water at the Site and because the toxicity reference value for C10–C12 aliphatic hydrocarbons represents both the upper end of gasoline range hydrocarbons and the lower end of diesel range hydrocarbons, the toxicity reference value for C10–C12 aliphatic hydrocarbons was selected as the PRG.

The RAO 8 PRG is focused on reducing the migration of COCs in groundwater to sediment and surface water. As a result, the groundwater source control measures should be designed to prevent C10–C12 aliphatic hydrocarbons from discharging to the Willamette River at concentrations exceeding 2.6 micrograms per liter. Pre-design characterization activities should therefore include characterization of C10–C12 aliphatic hydrocarbons using the best available detection limits possible.

### 2.3.9 Explain the Bis(2-Ethylhexyl) Phthalate PRG

#### Comment Summary

One comment was received that questioned the RAO 6 BEHP PRG of 135 µg/kg. RAO 6 is focused on bioaccumulative chemicals and wildlife exposures. However, because there was not a good relationship between tissue and sediment for BEHP, the basis for the 135 µg/kg BEHP PRG is unclear.

#### EPA Response

The BERA (Windward 2013) concluded that BEHP was an ecologically significant contaminant of concern. All documentation supporting that is found in the BERA. No relationship was found between sediment and tissue concentrations for this COC. Therefore, as stated in Appendix B4.2.1, “For those contaminants where site-specific biota-sediment accumulation factors could not identify relationships between sediment and tissue concentrations, a nationwide theoretical biota sediment accumulation factor of 4.0 was used for hydrophobic organic chemicals (USACE 2003, Appendix G).”

### 2.3.10 Address Miscellaneous PRG Issues

#### Comment Summary

Multiple comments were received on a variety of PRG issues that are summarized and addressed in this category. Those issues are:

- **Development of PRGs only for sediment.** Other commenters stated that PRGs should be established only for sediments and not for tissue, soil, surface water, or groundwater because these media are being addressed by Oregon DEQ. There should be no surface water PRG because it is not possible to achieve them through sediment remediation, ARARs related to these PRGs should be waived by EPA in the ROD.
- **Manganese PRGs.** One commenter noted that the groundwater PRG for manganese should not be based on tap water standards (i.e., protection of surface water for direct human consumption) because 1) the surface water in the Willamette River already meets this identified PRG; 2) groundwater concentrations of manganese are not predictive of surface water concentrations because manganese becomes oxidized as it moves into the surface water and precipitates out of solution; and 3) human use of surface water from the Willamette River requires pre-treatment. The commenter requested that EPA eliminate any groundwater PRG for manganese because groundwater concentrations do not correspond to surface water concentrations or to concentrations in treated potable water. To the extent EPA employs any groundwater criteria for manganese, the approach should be based on ecological hardness-dependent criteria.
- **Benthic risk.** One commenter provided a table of proposed PRGs for the Portland Harbor Site based on equilibrium concentrations, risk-based concentrations or the comprehensive benthic risk areas.

#### EPA Response

EPA disagrees that only sediment PRGs are appropriate for this Site. The baseline risk assessments determined that contaminated sediments and surface water presented unacceptable risk to human health and the environment. Transition zone water was found to exceed maximum contaminant level (MCLs) for drinking water exposures and posed unacceptable risk to ecological receptors.

Regarding the number of COCs, it should be noted that the Portland Harbor Site has numerous sources of contamination from a wide range of industries. Thus, while the use of focused COCs for the purpose of conducting evaluations in the feasibility study is considered appropriate because the remedial footprint of the focused COCs encompasses the majority of the contaminants at the Site, the large number and diverse nature of sources and contamination presenting unacceptable risk at the Site necessitate the identification of a relatively large number of COCs in multiple media to be addressed by the response action. This comprehensive set of COCs and PRGs will ensure that EPA's remedy addresses all of the risk to human health and the environment at the Site, and is monitored for subsequent five-year reviews, and addressed through source control actions.

Consistent with Section 121(d) of CERCLA and the NCP, remedial cleanup levels are to be developed based on ARARs including MCLs promulgated under the Safe Drinking Water Act and water quality criteria established under Sections 303 or 304 of the Clean Water Act or state-promulgated water quality criteria unless site-specific circumstances require risk-based goals be developed. 42 U.S.C. § 9621(2). Also, see the response in Section 2.3.1 for more detail about the statutory and regulatory basis for application of ARARs as cleanup levels.

EPA disagrees that PRGs should not be developed to address inputs to the Site. As noted in the response to LWG Dispute Issue 1d, the upland sources are not separate and distinct from the contamination in the river. The feasibility study report (USEPA 2016b) covers the in-river portion of the Site and thus the RAOs and PRGs must be developed to protect the media and pathways for which contamination is present. Since the RAOs and PRGs developed for this Site are based on the baseline risk assessments and ARARs, those areas of the Site that already achieve PRGs would not require action since the PRGs are already attained. EPA provides the basis for the establishment of PRGs for each RAO in Section 2 and Appendix B of the 2016 feasibility study report. As a result, it is appropriate to develop sediment PRGs for groundwater and river banks.

Regarding manganese specifically, the groundwater PRG was calculated using the oral reference dose developed by EPA's Office of Research and Development and posted in its Integrated Risk Information System database. See response to LWG Dispute 1n (Appendix A of this document).

The human health and ecological risk assessments both determined that exposure to COCs in surface water poses unacceptable risk to human health and the environment. As a result, EPA developed PRGs for surface water. Surface water PRGs include both risk-based PRGs ecological risk assessment and ARAR based PRGs based on State of Oregon water quality standards and National Recommended Ambient Water Quality Criteria. Consistent with CERCLA and the NCP and State of Oregon water quality regulations, Lower Willamette River will have to meet risk-based criteria or the more stringent of the federal and state human health and aquatic life water quality criteria at or before the completion of the selected remedy or else have this requirement waived. As described in Appendix K of the feasibility study report, EPA expects that remediation of contaminated sediments at the Site will reduce surface water concentrations. If EPA determines in the future that it is technically impracticable to achieve these criteria, it may waive them in a future decision document.

EPA disagrees that the PRGs were applied at locations and spatial scales that are inconsistent with the exposure scenarios for which they were developed, and regardless of whether there was unacceptable risk for a given location. For example, PRGs for RAOs 1 and 2 are being applied on a SDU basis. As described in the feasibility study report, site-wide and smaller spatial scales were used to evaluate each alternative including attainment of the RAOs. To conduct the smaller spatial scale evaluation, the Site was subdivided based on sediment dynamics and hydrodynamics of the shorelines and Swan Island

Lagoon, current and future uses (such as the navigation channel), and the preference of many receptors for shoreline habitat. Subdivisions will allow for a more precise analysis of risk reduction for each alternative. Several spatial scales were evaluated: 1) benthic risk was evaluated on a population level as the area exceeding RAO 5 PRGs, 0.5 RM was used for RAO 1 consistent with the BHHRA (Kennedy/Jenks 2013), 1 RM was used for RAOs 2 and 6 for the dietary exposure of humans and ecological receptors that consume fish and shellfish, and Site-wide was used for RAO 2. The Site was also divided into 14 individual regions of the river that were designated as SDUs. The SDUs correspond approximately to the estimated 1-mile exposure area for which recreational fishing was evaluated in the BHHRA and to the home range of species such as smallmouth bass, hooded merganser, osprey, bald eagle and mink that were evaluated in the BERA (Windward 2013).

LWG provided a revised set of sediment PRGs based on comments on an earlier version of the feasibility study. The basis for many of the revised PRGs is based on revised background estimates, application of the comprehensive benthic risk approach and application of a site-use factor. EPA has considered these comments in the development of the PRGs presented in the feasibility study report and proposed plan (USEPA 2016c). In addition, EPA has explained previously the approach for developing PRGs protective of the benthic community, its approach to developing background estimates and the basis for not applying the site-use factors. Finally, the basis for EPA's PRGs is well documented in Appendix B of the feasibility study report. Additional responses to comments on PRGs may be found in the responses to LWG Dispute Issues 1d, 1i, 1j, 1m, 1n, and 1q and Union Pacific Railroad Dispute Issue 2 (Appendix A of this document).

### 2.3.11 BEHP Should Not Be a COC

#### Comment Summary

Three commenters suggest that BEHP should not be considered a COC. Two of the commenters note that risk associated with BEHP is not widespread, and ecological hazard quotients only slightly exceed the interim target. One commenter states there are numerous problems with concluding alternatives are not protective due to BEHP risks. They also state that BEHP exceedances only occur in a small area within Swan Island Lagoon and that EPA is inconsistent in assessing protectiveness because EPA did not consider risk reduction of ENR within Swan Island Lagoon. Another commenter states that BEHP is a ubiquitous chemical in urban runoff, a commonly identified cross-contaminant in sampling and analysis equipment, and not the focus of proposed cleanups in the harbor.

#### EPA Response

The BERA (Windward 2013) determined that BEHP posed a risk to wildlife through the consumption of prey. As noted in the comments, the PRG for BEHP was exceeded in many locations at the Site and by more than 10 in Swan Island Lagoon for Alternatives B and D. Thus, EPA concluded that Alternatives B and D are not protective of wildlife. EPA's feasibility study did not consider risk reduction from ENR within Swan Island Lagoon as a conservative approach given ENR's long-term effectiveness in achieving cleanup levels relies on MNR. However, EPA has calculated risk reduction with ENR within Swan Island Lagoon and has provided updated risk calculations in the ROD that take into account the uppermost effectiveness of ENR to bound possible benefits of its application. However, even taking ENR into account, Alternatives B and D are still not protective of wildlife. Finally, EPA disagrees that the evaluation of protectiveness is inconsistent. The tables presented in Appendix J identify areas of the Site where an HQ greater than 1 exists following construction. This information has been used to evaluate protectiveness on a river mile and sediment decision unit basis. Based on the results of the BERA, BEHP was identified as a COC for the Site. EPA acknowledges that BEHP is not a primary concern for ecological

receptors at the Site. BEHP is not a focused COC, and RALs were not developed for BEHP. However, the remedy is anticipated to address risk posed by BEHP by addressing the focused COCs will be confirmed by future monitoring.

EPA used validated data that were not qualified in any manner to indicate cross-contamination occurred. Further, the ubiquity of a COC is not reason to dismiss its risk. BEHP sources are known to exist in Portland Harbor including stormwater and certain upland facilities. Ongoing source control measures are expected to further reduce BEHP releases to the river via stormwater inputs.

## 2.4 Surface Water

### 2.4.1 Address Feasibility Study Errors Related to Surface Water

#### Comment Summary

Three comments were received regarding how surface water was addressed in the feasibility study report (USEPA 2016b). Most of these comments were presented as analysis errors in Appendix K of the report:

- “EPA used flow weights for averaging surface water data that are the opposite of the actual average annual river flow conditions. EPA assumed 240 days of the year were in a high flow condition, when the U.S. Geological Survey Portland river gauge data show that low flows (less than the long-term average of 33,000 cubic feet per second) occur about 250 days out of the year.”
- “EPA used river mile 11 West and Navigation Channel data to calculate weighted average surface water concentrations (SWACs) for the Site and for concentrations entering the Site. Using these same data to represent both locations on the river results in inaccurate determinations for both locations.”
- “Although perhaps a typographical error, EPA indicates it subtracted the concentration entering the Site from the average site concentration to obtain concentrations for the “Downtown Reach.” As written, such a calculation would produce the contribution from the Site instead.”
- “EPA assumes that post-construction surface water concentrations will decrease proportional to the percent reduction in sediment SWACs. This simplistic assumption ignores other contributions to surface water, most notably the upstream concentrations entering the Site. As a result, EPA estimates much greater percent reductions for the alternatives than is possible. For example, EPA calculates 92 percent reduction in Site surface water concentrations for Alternative G, but correctly accounting for upstream inputs would place this estimate at only about a 50 percent reduction.”
- “EPA also ignores within-site upland sources such as National Pollutant Discharge Elimination System (NPDES)-permitted stormwater and NPDES-permitted process and cooling water discharges that are beyond the control of sediment remedies. For example, the annual loading summary provided in Table 6.1-11 of the EPA-approved remedial investigation shows that nearly 30 percent of the PCB load to the Site comes from stormwater.”

One commenter expressed concerns that EPA has not sufficiently recognized contaminant loading from surface water sources (i.e., stormwater and upstream) or accounted for the reduction in surface water source concentrations.

## EPA Response

The following address the specific concerns expressed by the commenters with the water quality analysis:

- The calculations assumed high flow conditions for 8 months out of the year, low flow conditions 3 months out of the year and stormwater induced flow conditions 1 month out of the year. EPA acknowledges that high flow conditions (approximately 60,000 cubic feet per second) do not occur 8 months out of the year. EPA assumed the low flow conditions sampled in September 2006 occur approximately 3 months out of the year (August – October), whereas the stormwater induced flow conditions occur approximately 1 month out of the year (November). As noted in Section 3.1.4.2 of the remedial investigation report (USEPA 2016a), the Willamette River average daily mean discharge, as measured over the past 35 years is 33,000 cubic feet per second. Because the surface water data used to calculate reductions in surface concentrations did not include samples that represent this average flow conditions, the high flow data were considered more representative of the average flow condition than either the low flow condition or the stormwater induced flow condition and thus was assumed to occur 8 months of the year (December – July). This assumption is considered appropriate for a feasibility study level evaluation of reductions in surface water concentrations.
- As described in Section K3.3 of the feasibility study report (USEPA 2016b), the upstream contribution was estimated using the results from RM 11M and RM 11W. RM 11E was used in the estimate of site concentrations since it is affiliated with the RM 11E project area and is a known source of contamination.
- The feasibility study report is correct as written. As noted in Section K3.3 of the feasibility study report, the Site contribution was estimated by subtracting the averaged “downtown” surface water results from the average site surface water results. Downtown results were estimated based on an average of the RM 11W and RM 11M stations. Site results were estimated based on an average of the RM 11E, RM 6.3 NS, RM 6.3 NB, RM 3.9 NS, RM 3.9 NB, MC NS, MC NB, RM 2E, RM 2M, and RM 2W results.
- EPA did not include the upstream contaminant contribution in the evaluation of remedy performance because it is expected that source control actions, as well as actions taken within the broader Willamette River watershed to reduce contaminant loading, will further improve upstream water quality. Since the reductions are uncertain, monitoring will need to confirm actual water quality in the river.
- The evaluation conducted by EPA does not consider the contribution from stormwater because the expected decrease in stormwater contaminants is unknown. As a result, it is assumed that the reduction associated with stormwater is proportional to the reduction associated with each of the alternatives.

In the surface water analysis approach included in Appendix K of the feasibility study report (USEPA 2016b), EPA subtracted out the contribution from upriver sources, acknowledging other inputs to the Site. Since EPA further assumed in the feasibility study report that all upland sources to the river would be controlled, the only remaining input to the surface water is contaminated sediment and water from upstream of RM 15.9. EPA disagrees with assertions that stormwater, groundwater, and upstream inputs will not change since DEQ has been working with entities to control upland and upriver sources

(RM 11.8 to RM 16.6) to the Site throughout the remedial investigation/feasibility study process and will continue these efforts post-ROD. Because background is based on conditions upstream of RM 15.9, recontamination would only reach background levels. Other sources are expected to be adequately address as discussed in the Section 2.27.1 of this responsiveness summary.

EPA recognizes that the site conditions (including surface water runoff) have changed since the start of the project and anticipates they will continue to change as previously stated. EPA will consider new technically sound data during remedial design.

## 2.4.2 Compliance with State and Federal Standards

### Comment Summary

A total of 37 comments were received that expressed concern about meeting water quality standards. Most (24) were form comments received by email that read:

- “The community expects the final remedy to comply with state environmental quality, especially the water quality criteria for the PTW contaminants. PCBs, dioxins and DDTs in water and fish must meet state water quality standards.”

Ten other comments agreed with this statement, and many also cited the Clean Water Act. Those comments include:

- “In terms of the final remedy, I ask that it comply with state environmental quality, especially the water quality criteria for the principle threat waste contaminants. PCBs, dioxins and DDTs in water and fish must meet state water quality standards. As well, I ask that the final cleanup names a specific goal date for the lifting of the Fish Consumption Advisory in regards to PCBs within the Portland Harbor area.”
- “ALL standards, including the drinking water and surface water standards should be met after the cleanup is complete.”
- “We would hope that before the superfund cleanup commences that there will be much more stringent requirements in place. Goals should have zero tolerance for pollutants where ever possible. Monitoring the entire site should be in perpetuity and should contain no contingencies based on a best guess but concrete facts.”
- “I think the clean water compliance act should be enforced.”
- “I expect the final remedy to comply with state environmental quality, especially the water quality criteria for the PTW contaminants. PCBs, dioxins and DDTs in water and that fish must meet state water quality standards.”
- “Meet threshold requirements for protectiveness including Clean Water Act standards.”
- “Comply with State water quality and hazardous substance remedial action rules for risk.”

### EPA Response

EPA acknowledges the commenters’ concerns about water quality and that the cleanup should achieve Clean Water Act criteria. Contaminants in surface water at the Site come from resuspension and/or dissolved phase flux from the sediment bed, river banks, groundwater, and stormwater and, to a lesser extent, from upstream. As described in Section 6.1 of the remedial investigation and stated in Section

1.2.3.3 of the feasibility study report (USEPA 2016b), concentrations of contaminants in surface water at the Site are generally higher than those entering the upstream limit of the Site (based on sampling at RM 16) under all flow conditions. The highest contaminant concentrations in surface water at the Site were found near known sources. EPA's proposed plan (USEPA 2016c) focuses on the cleanup of sediments and river banks to reach cleanup goals in several in-river media, including surface water and pore water, whereas separate source control actions under the authority of DEQ focus on reducing contaminants from groundwater and stormwater.

EPA's cleanup will comply with substantive requirements of the Clean Water Act. First, the final remedy has established surface water and groundwater cleanup levels for many contaminants based on risk-based remediation goals that are more stringent than Clean Water Act criteria, and for other contaminants based on Clean Water Act criteria and/or state promulgated, numeric water quality criteria, and the Safe Drinking Water Act. The cleanup levels for RAO 3 (surface water/human health) and RAO 4 (groundwater/human health) are based on the lower of the federal National Recommended Water Quality Criteria established under Section 304(a) of the Clean Water Act, Oregon water quality criteria, MCLs, and non-zero MCL goals, as presented in Table 2.1-4 of the feasibility study report and in Table 17 of the ROD.

The ecological risk-based cleanup levels were developed from toxicity reference values protective of ecological receptors and used in the BERA (Windward 2013). Toxicity reference values for water were selected as risk-based cleanup-levels for RAO 7 (surface water/ecological) and RAO 8 (groundwater/ecological). The cleanup levels for RAO 7 are based on the lower of the National Recommended Water Quality Criteria and Oregon water quality criteria only when risk-based values are not available or are greater than these criteria, as presented in Table 2.1-4 of the feasibility study report. EPA expects that remediation of contaminated sediments in conjunction with source control measures will reduce surface water contaminant concentrations to levels that meet state water quality standards. Additional source control efforts will be required within the Willamette River watershed to further reduce the levels of these contaminants. Monitoring of surface water will be conducted to confirm reductions in surface water contaminant concentrations and monitor compliance with state water quality standards.

Additionally, the remedy requires that implementation of cleanup actions must comply with the substantive requirements of the Clean Water Act. Section 401 of the Clean Water Act and Oregon water quality regulations as ARARs require cleanup actions that may result in the discharge of pollutants to surface water be implemented in a manner that reasonably assures that the activity will not violate applicable state water quality standards by the imposition of effluent limitations, other limitations, and monitoring requirements. During cleanup, short-term exceedances of some state water quality standards are possible, particularly when sediments are dredged. Under Oregon state law, Oregon Administrative Rules 340-041-004, short-term degradation of surface water is allowable if the benefits of the lowered water quality outweigh the short-term environmental impacts. This evaluation will be conducted during remedial design. Conditions on the dredging and capping will be required based on a water quality monitoring plan that outlines how the cleanup activities will take place to minimize sediment resuspension that would affect water quality, and if necessary, ramp up best management practices like dredging controls where sampling indicates unacceptable levels of migration of dissolved or particulate bound contaminants. Section 2.17 of this responsiveness summary provides more detail on monitoring to be conducted during and after cleanup.

### 2.4.3 Address Issues with Assignment of MCLs

#### Comment Summary

Comments were received asserting that EPA incorrectly establishes Safe Drinking Water MCLs as ARARs for the Site and stating that Oregon water quality standard regulations designate the Lower Willamette River as a potential public and private water supply only following adequate pretreatment citing Oregon's designated use regulation for the Willamette Basin, Oregon Administrative Rules 340-041-0340, specifically Table 340A. Commenters also extended their argument that MCLs should not be ARARs for groundwater cleanup levels (1,1-DCE, 2,4-D, perchlorate, and 2,4,5-TP) and regional screening levels (manganese).

LWG expressed that it is not appropriate to assign MCLs to surface water and/or groundwater because they are "likely not achievable," not required for protectiveness, and not relevant to "reasonable and likely uses of groundwater." LWG suggested that if MCLs are retained as surface water or groundwater PRGs, they should be "applied at the theoretical point of distribution after treatment, consistent with Oregon and federal law," citing Oregon's designated uses for the Willamette Basin, Oregon Administrative Rules 340-041-0340, Table 340A; and Safe Drinking Water Act regulations, 40 Code of Federal Regulations Part 141, Section 141.23(a).

#### EPA Response

MCLs are appropriately identified as ARARs for the Portland Harbor Site as cleanup levels for surface water and groundwater. CERCLA Section 121(d) requires: (1) that any remedial action selected shall attain a degree of cleanup of hazardous substances, pollutants, and contaminants released into the environment and control of further releases at a minimum which assures the protection of human health and the environment; and (2) for any hazardous substance that will remain on site, such remedial action shall require a level or standard of control which at least attains Maximum Contaminant Level Goals established under the Safe Drinking Water Act, and water quality criteria established under Section 304 or 303 of the Clean Water Act. 42 U.S.C. § 9621(d)(1) and (2)(A). MCLs are relevant and appropriate under the circumstances of the release at Portland Harbor because the designated beneficial uses of the lower Willamette River include public and private drinking water supply (Oregon Administrative Rules 340-041-0340, Table 340A). Likewise, all ground water of the state, including the ground water adjacent to and under the lower Willamette River, are to be protected for the beneficial use of domestic drinking water supply. (Oregon Administrative Rules 340-040-0020(3)), which is as stringent or more stringent than the "EPA Guidelines for Ground-Water Classification" (December, 1986) (See 55 Federal Register 8732, March 9, 1990). Releases of hazardous substances which exceed applicable promulgated water quality standards and relevant and appropriate Safe Drinking Water Act standards for groundwater and surface water cleanup have occurred to groundwater that is discharging to or under the river within the Site or has the potential to discharge to the river. For further detail about the statutory and regulatory requirements for applying MCLs under CERCLA and at the Portland Harbor Site, see the response in Section 2.3.1. and LWG Dispute comment 1m response (Appendix A of this document).

EPA disagrees with the comment that "MCLs should not be considered ARARs at the Portland Harbor Site because the Oregon statute designates the Lower Willamette River as a potential public and private water supply only following adequate pretreatment" citing to a note in Table 340A.

However, there is other regulatory language the commenters ignored that does not support their position. Oregon Administrative Rules 340-041-0340(1) states: "Water quality in the Willamette Basin . . . must be managed to protect the designated beneficial uses shown in Table 340A (August 2005)." Table

340A lists both public and private domestic water supply as beneficial uses with a notation that states in full: "With adequate pretreatment and natural quality that meets drinking water standards." On its face, the notation does not void the state's regulatory mandate to manage water quality to protect the drinking supply use, but rather seems to be indicating what conditions should exist or occur for a consumer to take advantage of the designated use. Oregon Administrative Rules 340-041-340(1) supports why it is appropriate for the Portland Harbor remedy to protect the beneficial use of drinking water supply by requiring both surface water and groundwater discharging to the river to meet MCLs. Additionally, most PRGs for surface water and groundwater are based on more stringent water quality standards, not MCLs.

EPA also disagrees with the commenters that MCLs are not achievable through the planned remedial actions. No data or studies have been conducted that support that assertion. Although in-river sediment remedies and upland source control measures may not achieve MCLs immediately, compliance with MCLs will be monitored during implementation of the remedy. If monitoring indicates MCLs may not be achieved, further evaluation will be required to determine what additional source control measures or other actions may be necessary or whether meeting MCLs is not technically practicable. If it is demonstrated that achieving MCLs is not technically practicable, a waiver of that ARAR may be necessary.

Lastly, commenters argue that if MCLs are applied, they should only be applied at the theoretical point of distribution consistent with the Safe Drinking Water Act regulations and are not required for protectiveness. The Safe Drinking Water Act regulates public water supplies and sets primary drinking water standards for such systems. CERCLA, however, is a remedial statute and explicitly requires that any remedial action shall require a level or standard of control which at least attains Maximum Contaminant Level Goals established under the Safe Drinking Water Act, and water quality criteria established under Section 304 or 303 of the Clean Water Act. 42 U.S.C. Section 9621(d)(A) when relevant and appropriate to the releases at the Site. The Safe Drinking Water Act MCLs are not applicable to the circumstances of the releases and risks being addressed in this remedy decision, but they are relevant and appropriate given the beneficial uses of both groundwater and the river and releases of hazardous substances to both of those media within the Site.

## 2.5 Principal Threat Waste

### 2.5.1 EPA's Identification of PTW that Cannot be Reliably Contained is Flawed

#### Comment Summary

One comment was received that stated that the presence of highly toxic or mobile material does not by itself constitute PTW and that EPA errs by designating "highly toxic PTW" in a vacuum, solely in comparison to the risk level of detected concentrations of contaminant in sediments. To comply with guidance, EPA is required to also determine that such concentration is present in material that "cannot be reliably contained," or that the "toxicity and mobility ... combine" to pose a high risk, or that the toxicity is high when taking into account "the potential mobility of the wastes." EPA states, "'reliably contained' was not used in identifying PTW in the first instance, but rather it was used to determine what concentrations of already-identified PTW could be reliably contained." This contradicts EPA's guidance, which discusses the "reliably contained" criterion as part of PTW identification and not as a modifier once PTW has been identified. Further, EPA admits that all COCs at concentrations present at the Site, with just two exceptions-chlorobenzene and naphthalene-can be reliably contained. Therefore, none of the areas where these two contaminants are absent should be designated as PTW. Only the

areas that EPA designates as "not reliably contained" have the potential to actually be defined as PTW, yet such an evaluation has not been performed. Without this step, no area can be designated as PTW.

### **EPA Response**

Please see EPA's responses to Legacy Site Services (LSS) Dispute Issue 17 and LWG Dispute Issue 2c (Appendix A of this document).

## **2.5.2 Provide Justification for PTW for Total PAHs**

### **Comment Summary**

One commenter stated that there appears to be an error on Table 13 of the proposed plan where it lists a PTW RAL for Total PAHs of 870,000 µg/kg. PTW applies to cPAHs not total PAHs. The "Highly Toxic PTW Threshold" for cPAHs is identified as 106,000 µg/kg BaP eq on Table 6 of the proposed plan, consistent with Table 3.2-1 and Figure 3.2-3 of the 2016 feasibility study report. The cPAH PTW criteria should be listed. If this is not an error, please provide justification for the assignment of a PTW value of 870,000 µg/kg for Total PAHs.

### **EPA Response**

The value of 870,000 µg/kg in Table 13 of the proposed plan (USEPA 2016c) is a cPAH concentration converted to total PAHs using an empirically derived relationship between the two. Thus, the  $10^{-3}$  risk level was calculated for cPAHs and then transformed to total PAHs.

## **2.5.3 Reliance on Remedial Investigation Mechanistic Food Web Model Is Inappropriate**

### **Comment Summary**

One comment was received about the mechanistic food web model:

- "As a starting point, EPA has inappropriately relied on the remedial investigation Mechanistic Model (Windward, 2015) to define a PTW sediment concentration threshold for PCBs (and several other contaminants). EPA guidance defines PTW as a "source material" that "acts as a source for direct exposure." (EPA 1991). The remedial investigation Mechanistic Model, in contrast, is used in the evaluation of indirect human exposure through the fish consumption exposure pathway. It is erroneous to use the remedial investigation Mechanistic Model to designate PTW levels.

Even if it were appropriate to use the remedial investigation Mechanistic Model for purposes of establishing PTW levels, EPA has misapplied it here. EPA has chosen to apply the PTW concentration thresholds it has developed for the fish consumption exposure pathway on a point-by-point basis to identify PTW "source materials." This application is contrary to the assumed exposure area in the remedial investigation mechanistic report and is therefore inappropriate and incorrect. Most fish have wide home ranges and, consequently, their exposure will not be restricted to locations within the study area where sediment concentrations exceed the PTW threshold. Finally, the PTW threshold concentration is calculated under the inappropriate assumption that a subsistence fisher will, throughout his/her lifetime, exclusively consume fish from Portland Harbor that have only been exposed to sediments containing the PTW threshold concentration. Clearly, this last assumption adds yet another layer of implausible conservatism to EPA's misguided approach to defining a PTW threshold in sediments."

## EPA Response

The mechanistic food web model was appropriately developed, parametrized, calibrated and applied to develop risk-based PRGs associated with RAOs 2 and 6 and, by extrapolation, PTW thresholds. EPA responses to comments on the Mechanistic Food Web Model are provided in Section 2.11 of this responsiveness summary. The definition of source material in EPA guidance states that source material is defined as “material that includes or contains hazardous substances, pollutants or contaminants that act as a reservoir for migration of contamination to groundwater, to surface water, to air or acts as a source for direct exposure.” Thus, the definition of source material is not limited to material that acts as a source for direct exposure. Although biota tissue is not specifically mentioned, the concept of contaminated sediments acting as a source of contamination to biota tissue is consistent with the guidance.

Regarding the scale over which PTW is applied, the highly toxic PTW threshold is based on the sediment concentration that equates to a  $1 \times 10^{-3}$  risk level without consideration of exposure scale. There is nothing in EPA guidance that requires consideration of exposure scale in the development of PTW thresholds. It should be noted that the risk assessment determined that many areas of the Site exceed the  $1 \times 10^{-3}$  risk threshold for PCBs. For example, Table 5-74 of the BHHRA (Kennedy/Jenks 2013) shows that the site-wide risk associated with PCBs and the subsistence fish consumption exposure pathway is  $9 \times 10^{-3}$  which is well above the PTW risk threshold. As a result, it is appropriate to establish a highly toxic PTW threshold for PCBs based on  $1 \times 10^{-3}$  risk and apply that threshold across the Site. The risk assessment assumptions developed for the subsistence fisher are appropriate under a reasonable maximum exposure scenario.

See also response to LSS Dispute Issue 2 and LWG Dispute Issue 2c (Appendix A of this document) for more discussion of PTW identification at the Site and Section 2.11.1 of this document for more information on the mechanistic food web model.

## 2.5.4 Address Miscellaneous PTW comments

### Comment Summary

Several PTW miscellaneous comments were received. They are:

- PTW determination is unnecessary and inconsistent with guidance, the NCP, and practice which results in EPA incorrectly labeling as PTW large areas of sediment with relatively low concentrations and/or low toxicity of COC, or sediments that do not act as a source of direct exposure, and can be reliably contained.
- The assessment or identification of PTW and non-aqueous phase liquid (NAPL) (adjacent to Arkema) is inaccurate.
- A biased approach was used for assignment of remedial technologies to sediment containing PTW and NAPL.

## EPA Response

Please see LSS Dispute Issues 2 and 17, and LWG Dispute Issue 2c (Appendix A of this document).

## 2.6 Remedial Action Levels

### 2.6.1 Address Concerns with Establishment and Application of RALs

#### Comment Summary

Many commenters believe that EPA's proposed plan arbitrarily establishes different RALs to different SDUs. It was noted that assigning different RALs could result in recontamination of downstream areas if higher RALs were utilized upstream. In addition, it was noted that the feasibility study report and proposed plan did not provide sufficient explanation of the basis for this decision. It was also noted that during remedial design, additional sampling will be conducted that may identify additional risk associated with dioxin/furan, yet the cleanup levels will remain the same.

Other commenters stated that EPA's selection of Alternative F for SDU 7W is arbitrary and capricious because it is based on a scientifically inappropriate conceptual site model (CSM), inaccurate baseline sediment concentrations and assumed risk, incorrect risk drivers, inconsistent post-construction risks among SDUs, and a faulty estimation of risk reduction to justify large dredge volumes.

Some commenters questioned the application of RALs in certain parts of the Site. For example, PAH RALs should not be applied in the navigation channel (RAL comment). The RALs must be applied only in exposure areas where the baseline risk assessments found unacceptable risks from the RAL chemicals. As discussed in LWG comments, EPA's preferred alternative requires significant amounts of dredging at locations where exposure to the RAL chemicals driving the cleanup either does not occur, where PRGs for those chemicals are already met, or where the baseline risk assessments did not find unacceptable risk for a given contaminant/exposure pathway. The most dramatic example of this is the approximately 25 acres of dredging EPA plans in the navigation channel based upon preliminary remediation goals for polycyclic aromatic hydrocarbons (PAHs) developed for shellfish consumption, an exposure scenario that cannot occur in the navigation channel. No one goes clamming in 50 feet of water in the middle of the river.

Another commenter questioned the use of a 75 µg/kg RAL for SDU RM 7W because the focused COCs for SDU RM 7W were DDx/PeCDF/TCDD, not PCBs (proposed plan Table 16 (USEPA 2016c)). They noted that of the 8 SDUs with PCB listed as a Focused COC, 7 SDUs have a PCB RAL of 200 µg/kg and that remediating the sediment in this area to the 75 µg/kg PCB RAL would have a minimal effect on the concentration of DDx, PeCDF or TCDD in SDU RM 7W and would not be cost effective in reducing the site-wide PCB SWAC.

It was also noted that EPA's remedy selection improperly relies on SWAC values that were calculated using data that are more than a decade old. Consequently, the RALs established by EPA based on those SWACs reflect an outdated "snapshot" of Site conditions as they were 10 to 15 years ago, rather than current conditions.

One commenter stated that EPA should apply Alternative D or E RALs for non-focus COCs in SDU 7W or extend SDU 6W to include the entire Siltronic shoreline. The use of Alternative D or E RALS more appropriate for non-focus COCs would reduce the projected active remedy area that is unrelated to the focus COCs. Alternatively, applying Alternative F RALs for the focus COCs would result in post-construction concentration estimates that are consistent with other SDUs. Either of these approaches would avoid the unwarranted designation of much of the Siltronic shoreline for river bank remedy.

It was further noted that DDx risks at RM 7W are similar for Alternatives B through E and equate to 10<sup>-7</sup> risk for Alternative F. The use of this overly aggressive RAL for DDx results in a more stringent risk

standard for SDU RM 7W than the rest of the Site, is not necessary, nor more protective when compared to chemicals such as PCBs and is thereby arbitrary and capricious.

One commenter stated that EPA's determination that sediments near RM 10.7 exceed RALs and must be remediated as PTW is not based on available data and is therefore arbitrary and capricious. Another commenter requested an explanation for why there are PRGs for the other 64 COCs that already have regional thresholds but have no RALs in the alternatives. Finally, one commenter requested a Site remedy that focuses on active remediation of the highest contaminant concentrations and relies on the following RALs:

- PCB RAL of 1,000 ppb
- DDE RAL of 1,000 ppb
- cPAH (as BaPEq) RAL of 20,000 ppb

### **EPA Response**

EPA's proposed plan (USEPA 2016c) explained the basis for the different RALs in Alternative I; however, after reviewing public comments, EPA has selected Alternative F with modifications as the final remedy. EPA agreed that applying different RALs, particularly, higher RALs upstream of lower RALs could be problematic for achieving the ultimate cleanup goals. The selected remedy applies the same remedial action levels (F RALs) throughout the Site, with the exception of the navigation channel where the remedy will target PTW and sediment contamination exceeding the Alternative B RALs because of the differences in water depth, sediment transport potential and exposure potential. EPA's final selected remedy addresses the majority of the comments concerned about the application of different RALs for the same COC, including claims that the selection of different RALs in different nearshore areas is arbitrary and capricious.

Regarding application of PAH RALs in the Navigation Channel, the remediation of PAH contamination within the navigation channel is based on risks to the benthic community and the human health shellfish exposure scenario. Although the commenter states that human consumption of shellfish is an exposure scenario that cannot occur in the navigation channel because no one goes clamming in 50 feet of water in the middle of the river, there is no information to support this claim. It should be noted that RALs are not the final cleanup levels. The ROD established final cleanup levels that will be attained through a combination of active remediation (such as, capping and dredging) and monitored natural recovery. Cleanup levels must be met throughout the Site, including the navigation channel.

Additional information regarding the application of PAH RALs in the Navigation Channel may be found in EPA's response to LWG Dispute Issue 1d (Appendix A of this document) of this responsiveness summary.

It was noted that EPA established PRGs for 64 COCs but developed RALs for only 6 focused COCs. As described in Section 3.4.1.1 of the feasibility study report (USEPA 2016b), focused COCs are those that the distribution encompasses the majority of the spatial extent of contaminants posing the majority of the risks as identified in the baseline risk assessments. RALs were developed for each of the focused COCs and were used in the feasibility study only for the development of SMAs. SMAs establish the remedial footprint to be addressed through capping and dredging during implementation of the remedy.

Regarding the proposal to establish RALs for PCBs at 1000 µg/kg, DDE at 1000 µg/kg and cPAHs (as BaPEq) at 20,000 µg/kg, EPA finds that these RALs would result in Site-wide SWACs well above the PRGs established for the Site. For example, a PCB RAL of 1000 µg/kg would result in a site-wide SWAC of approximately 55 µg/kg. Based on existing information and the lines of evidence used for identifying MNR potential (see feasibility study report Appendix D8, EPA concludes that use of the RALs recommended by the commenter likely would not achieve final cleanup levels within a reasonable timeframe and potentially would not support MNR recovery. Regarding the remediation of contaminated sediments in the vicinity of RM 10.7, see the response to UPPR Dispute 6 (Appendix A of this document).

## 2.7 Remedial Action Objectives

### 2.7.1 Implement Changes to Remedial Action Objectives

#### Comment Summary

Comments pertaining to RAOs were submitted by several parties, including the PCI Group, EVRAZ Inc., Cascade General, and Portland General Electric. One commenter stated that RAOs should not be required for exposure media, pathways, and receptors for which the risk assessments conclude there is no unacceptable risk. EVRAZ Inc. comments also stated that the overall RAO language be changed to focus on reducing risk instead of reducing COC concentrations. Portland General stated that RAO 3 should be eliminated because current water sampling conducted by DEQ shows the risk to direct human health surface water exposure to be minimal. Another commenter (EVRAZ Inc.) stated that RAOs 3 and 7 should be removed because the remedial action cannot control the quality of surface water flowing into the Site, and RAOs should reflect objectives that are achievable. EVRAZ Inc. also proposed that RAOs 4 and 8 be removed because these RAOs pertain to reducing groundwater COC concentrations to minimize recontamination of sediment and surface water, and are not about exposure to the groundwater itself. Cascade General commented that EPA's proposed plan should be revised to provide a thorough analysis of the anticipated long-term effects of controlling the city's CSO discharges (e.g., Big Pipe Project) on meeting the site-wide RAOs, and, if supported by this analysis, implement less aggressive remedial measures such as applying monitored natural recovery to a wider area. Comments pertaining to RAO 9 are included in Section 2.26 of this responsiveness summary.

#### EPA Response

The cleanup strategy for the Site was developed to address all contaminated media and complete exposure pathways that pose unacceptable risk within the river, including sediment, biota, surface water, groundwater, and river banks. The nine RAOs were developed to address the human health and ecological risks posed by COCs at the Site, and reduce the potential for recontamination. The remedial approach is to address the contaminated sediment within the Site, reducing concentrations, exposure to and the bioavailability of COCs in all affected media (sediment, biota, surface water, groundwater, and river banks). To achieve the risk reduction in all media, it is imperative that all nine RAOs are addressed to reduce the overall risk to people and ecological receptors.

Reducing risks from direct contact with COCs in surface water, as described in RAOs 3 and 7, is an important component of the overall remedy. EPA recognizes that upstream surface water quality is a factor in meeting surface water cleanup levels, but due to sediment contamination, surface water concentrations within the Site are generally higher under all flow conditions than those entering the upstream limit of the Site. Additional surface water data will be obtained following remedy implementation to compare the COC surface water concentrations within the Site boundaries to upstream and downstream values. If the data indicate that the inflow of upgradient surface water is

prohibiting attainment of surface water quality criteria, EPA will make the determination as to whether further action (like additional upland or upriver source control) is warranted. Controlling the migration of COCs in groundwater that may impact sediment and surface water quality, as described in RAOs 4 and 8, is also an important component of the overall remedy. Elevated COCs in groundwater can negatively impact transition zone water quality in sediment and increase risks to benthic organisms, fish, and aquatic plants. Direct contact with groundwater discharging via seeps is also a potential exposure pathway. RAOs 4 and 8 are focused on containing and reducing migration of COCs from groundwater to surface water and biologically active areas of sediment. Should groundwater not be addressed adequately under DEQ's actions, EPA may, at a future time, determine if action is warranted under CERCLA to further address groundwater contamination. Removal of RAOs 4 and 8 is not warranted.

The RAOs and the proposed remedy take into account ongoing source control efforts, including the control of CSO discharges, stormwater discharges, groundwater discharges, and erosion of river bank soils. The effectiveness of monitored natural recovery assumes that source control will be implemented and discharges from CSOs will not continue to impact the waterway. The elimination of these discharges in conjunction with active sediment remediation through dredging and capping will facilitate natural recovery processes and allow the remedy to meet the RAOs in a reasonable timeframe. Comments pertaining to RAO 9 are addressed in Section 2.26 of this responsiveness summary.

### 2.7.2 Incorporate Newer Data in Surface Weighted Average Calculations

#### Comment Summary

Six comments were received regarding the data used for calculating surface-area weighted concentration (SWAC) values. Commenters recommended that new SWACs be developed based on more recent data.

Commenters said that the SWAC calculations did not take into account the most recent data available and thus misrepresent the current conditions. It was stated that more recent PCB samples have been taken, and including the data would reduce the initial SWAC for PCBs. They also referred to a 2013 LWG evaluation of small mouth bass PCB tissue measurements made in 2002, 2007, and 2012 which indicate declines in tissue concentrations across almost all areas of the Site. Further, it was stated that 2014 sedimentation bathymetry data and 2014 site-wide sediment PCB data support a downward trend in contaminant concentration in surface sediments due to the effects of natural recovery at the Site. LWG also commented that because only a limited number of dioxin/furan samples are available and detected, the SWAC calculation across the Site for each congener is flawed.

#### EPA Response

EPA is anticipating that new data will be taken into account during remedial design and implementation. Please see Section 2.10.2 of this responsiveness summary and EPA's response to LWG Dispute Issue 1d for additional details regarding the data used, and the rationale for SWAC calculations (Appendix A of this document).

### 2.7.3 Address SWAC Reductions and Natural Recovery

#### Comment Summary

Three comments pertaining to SWAC reductions and natural recovery were received, as summarized below:

- The preferred alternative would take nearly twice as long to complete, but would only reduce the site-wide PCB SWAC by an additional 17 percent, to 40 µg/kg. This concentration is actually in the range of site-wide sediment concentrations measured in 2014 (Kleinfelder 2015), suggesting that the estimated benefit from the preferred alternative has already been at least partly achieved through natural recovery.
- The post-remediation SWAC reductions for DDx in the RM 7W was more than 60 percent. The SWAC reductions for PeCDF and TCDD were nearly an order of magnitude. LSS believes that this is too conservative since it does not take into account natural recovery. Remediation with natural recovery is protective of human health and the environment.
- EPA's overall PCB SWAC estimate in the Swan Island sediment decision unit for Alternative I is 48 µg/kg. However, this SWAC value reflects only the effect of remediation at dredged and dredge/cap areas of Alternative I and does not account for the effect of ENR. It is unclear why EPA has excluded the effect of ENR because EPA accounted for the effect of ENR on SWACs in the 2015 draft feasibility study report (USEPA 2015).

### **EPA Response**

EPA agrees with the importance of considering new data during decision making and that decisions should have built in flexibility to accommodate an updated understanding of site conditions. However, it is important to have a representative data set that establishes “baseline conditions” prior to initiating a response action. A decision-making process cannot undergo constant modification when data are collected at various times and locations throughout the Site. Therefore, at this time, EPA does not plan on using the 2015 Kleinfelder Report to revise the RALs used to develop remedial alternatives in the feasibility study report. Further, data presented in the 2015 report do not on their face appear comparable to previously collected remedial investigation data (10cm surface samples vs the 30cm samples collected in the remedial investigation), making the conclusions therein regarding trends questionable. However, some conclusions provided in the August 7, 2015 memo to Jim Woolford and Cami Grandinetti are reasonable and consistent with the Agency’s position, specifically that natural recovery is occurring in the Willamette and is anticipated to continue and that the food web model is a useful line of evidence for representing sediment and food web contaminant relationships. EPA expects remedial footprints to be refined based on data collected during remedial design. For example, if sediment concentrations have declined through natural recovery, pre-design sampling should result in a smaller remedial footprint (ROD Section 10.1.1.9).

EPA concurs that natural recovery is occurring within Portland Harbor and that it should be utilized in the sediment remedies, as evidenced by the fact that MNR represents the response action assigned to between 64 and 90 percent of the total area of the Site for all alternatives carried through the detailed analysis in the June 2016 feasibility study. However, the rate of natural recovery is expected to vary by location. Pre-design sampling will be used to ensure that the natural recovery is factored into the design and implementation of the sediment remedy and post construction monitoring will be used to evaluate natural recovery following remedy implementation.

For EPA’s additional responses to the comments summarized above, please see EPA responses LWG Dispute Issue 2b, LSS Dispute Issue 5, and LSS Dispute Issue 8 (Appendix A of this document).

## 2.7.4 Revisit Post-Construction SWAC Calculations

### Comment Summary

Comments pertaining to effect of sediment background and dredge residual concentrations on post-construction SWAC calculations were submitted by four commenters, as summarized below:

- The post-construction sediment concentrations are unrealistic, and SWACs do not account for dredge residuals or actual background concentrations of COCs. For example, some of the dioxin/furan, PCB, and DDx post-construction concentrations are below EPA's derived background concentrations. Post-construction SWACs less than EPA's arbitrary background concentrations are not feasible and are an artifact of the use of "zeroes," instead of a background or equilibrium-based value, for replacement values in SWAC calculations.
- The use of sediment equilibrium concentrations, such as the equilibrium calculation for PCBs calculated by LWG, are the most appropriate because it is not possible to clean up a sediment site below equilibrium concentrations; however, because equilibrium concentrations have not been calculated for most COCs in Portland Harbor, upstream background concentrations are the next best value to use in these post-remediation SWAC calculations.
- EPA's calculations of post-construction risk do not provide for meaningful comparisons. A larger remedial footprint may briefly result in decreased residual risk in the short period immediately after construction. However, within a relatively short period of time, reflecting a reasonable attenuation time-frame, the post-remedial action risk will be similar across alternatives due to the surface sediments reverting to actual river-wide equilibrium conditions. EPA's analysis fails to properly account for the post-remedy contaminant levels rising to meet background.
- SWACs calculated for SDU RM 3.5E for PeCDD are already near background values of 0.0002 µg/kg. Application of Alternative B RALs, which would not result in designation of an SMA adjacent to the Time Oil facility, would achieve a post construction SWAC of 0.000198 µg/kg, below the PRG. If rolling-river mile, the range is from 0.000116 to 0.000262 µg/kg in this area. If Alternative B RALs were applied, the highest post construction SWAC in this area would be 0.000214 µg/kg at RM 3.9E, essentially indistinguishable from background.

### EPA Response

Post-construction COC concentrations in areas assigned to dredging or capping were assumed to be zero, as the 2016 feasibility study report (USEPA 2016b) assumed clean material would be used for caps, and that the residual layer applied to dredged areas would consist of clean sand. This assumption allowed EPA to perform an equal comparative evaluation among the alternatives presented in the feasibility study report. While post-construction sediment concentrations of zero may not actually be realized, there is too much uncertainty during the feasibility study phase to accurately predict what the concentrations will be at each area addressed via active remediation. The absence of sufficient data needed to develop a defensible fate and transport model precluded estimating equilibrium COC concentrations with any degree of certainty in these actively remediated areas for any time-frame beyond the immediate post-construction period. Only empirical data collected post-construction will provide the actual results.

For the purpose of the feasibility study report, assumptions were made in order to evaluate and compare the performance of alternatives. As long as these assumptions are made consistently across

each of the alternatives, the comparative results are not biased based on a largely uncertain and speculative factor such as post remediated sediment concentrations.

EPA's position regarding the use of equilibrium values and the use of zeros as replacement values is further discussed in EPA's response to LWG Dispute Issue 1r and EPA's response to LSS Dispute Issue 8 (Appendix A of this document).

While the commenter is correct that SWACs for 1,2,3,7,8-PeCDD are driving the creation of the SMAs in this area, the SWAC and related RALs for each contaminant were evaluated and established at a site-wide level. The area is not evaluated based on PRGs, and individual areas above the designated RALs are taken into account, not the calculated SWAC at any one area. Figure 3.4-10 in the feasibility study report suggests that at least one sample in the area is above 0.0008 µg/kg and above the background values. This Site will be further evaluated during the remediation and design phase to determine if there is significant contamination and if remedial action is necessary.

## 2.7.5 Address Inconsistencies between SWACs and Baseline Risk Assessments

### Comment Summary

Two comments pertaining to the SWACs being inconsistent with the baseline risk assessments were received and are summarized below:

- The consequences of substantially diverging from the BLRA SWACs at this late date are not considered or discussed anywhere in the 2016 draft feasibility study report or proposed plan. The consequences, combined with other issues, like the zero replacement value, are widespread, impacting every post-construction risk estimate presented by EPA and skewing the overall evaluation of the alternatives' effectiveness.
- It is inappropriate to use any of these new subsampling methods because they will all create Site SWACs that are inaccurate and inconsistent with those used in EPA-approved BLRAs, which in turn causes the remedy selection process to diverge from an appropriate focus on reducing risks actually identified in the baseline risk assessments.

### EPA Response

The SWACs are a tool developed for the 2016 feasibility study report (USEPA 2016b) to compare alternatives to the No Action alternative and are not used nor discussed anywhere in the BERA (Windward 2013) or BHHRA (Kennedy/Jenks 2013). EPA's position regarding the two comments above is further discussed in responses to LWG Dispute Issue 1c and 1d (Appendix A of this document).

## 2.7.6 Effect of Initial Condition SWAC on Chosen Alternative

### Comment Summary

Comments pertaining to the impacts of the initial condition SAWC on the preferred alternative were submitted by four commenters, as summarized below:

- Initial Conditions determines the shape of the SWAC curve. When a higher value is used for the initial conditions, the resulting shape of the curve changes and the most intrusive and resource-consuming alternatives erroneously appear to provide more benefit in reducing the SWAC. This is a significant analytical and decision-making error because such alternatives actually provide much less benefit at a significantly greater cost than when the initial condition is more

appropriately represented by the lower actual values that reflect the documented conditions at the Site.

- In the 2016 feasibility study report, EPA used a new, inflated baseline SWAC (almost 2.5 times higher than used in the BHHRA) that resulted in correspondingly higher, but unsupported and unexplained, estimated risks. Such inflation of estimated current risks has the effect of improperly overstating projected risk reductions to be achieved by the more intensive alternatives, including Alternative I.
- A high initial SWAC of 208 ppb for PCBs was used to calculate percent reductions without an explanation or apparent scientific support. This significantly exceeds the initial condition SWAC of 85 ppb derived from the 2001-10 remedial investigation data used in EPA's draft 2015 feasibility study report and the BHHRA. EPA chose not to disregard the data, and EPA's use of the higher current SWAC impacts EPA's detailed analysis of alternatives since using a higher initial SWAC creates the appearance that the more aggressive alternatives achieve greater risk reduction.
- EPA calculated, using the Food Web Model and the new sediment SWAC of 208 ppb, an average PCB site-wide fish tissue concentration of 521 ppb. The comparable average site-wide fish tissue concentration in the BHHRA, based on actual tissue data collected in 2007 and earlier, is 227 ppb, which equates to a site-wide modeled sediment SWAC of 85 ppb. Using EPA's modeled tissue concentration of 521 ppb, the acceptable consumption rate based on the non-cancer endpoint would be 1.9 fish meals/year for the child scenario; whereas the actual BHHRA tissue concentration of 227 ppb results in an acceptable consumption rate of 4.2 meals/year. The above calculation of 1.9 meals/year for Alternative A (baseline) using EPA's fish tissue concentration is higher than the meals per year shown for Alternative A in Figure 4.2-2 of the 2016 feasibility study report, which presents 0.6 fish meal/year for the presumably same scenario. It appears that EPA is using the child scenario but altering the fish meal size from 3.5 ounces to the adult meal size of 8 ounces, which is clearly inconsistent with the BHHRA methods. Putting aside the reasonableness of a child consuming adult meal portions for long periods while still remaining a child, the result of EPA's poorly explained additional change to the exposure assumptions is to drive allowable fish meals even further down for the baseline condition. Combined with the artificially inflated new SWAC, this meal size change compounds the portrayal that the baseline condition is much worse than the actual BHHRA findings. Again, this further increases the perceived benefit of any SWAC and tissue concentration reductions assumed for the more aggressive alternatives.

### EPA Response

EPA's response to each of the four comments is as follows:

- While a concern of how the initial conditions affect the SWACs and chosen remedy are valid, the initial condition SWACs presented in the feasibility study report (USEPA 2016b) (Figure 3.4-1) of 92  $\mu\text{g}/\text{kg}$  for PCBs is very close to the value of 85  $\mu\text{g}/\text{kg}$  used by LWG in 2012. This evaluation is conceptual in nature, and the variations in SWACs across the SDUs are meant to show the effects of the chosen RAL at that level. While these can have an impact on footprints in this evaluation, further evaluation will be done to determine actual extent of contamination and costs during remedial design. A similar question is addressed by EPA in its response to LWG Dispute Issue 1d (Appendix A of this document).

- As stated in the above response, the baseline SWAC of 92 µg/kg was used in calculation of the PCB RAL curves. Please see EPA’s response to a similar question in LWG Dispute Issue 1d (Appendix A of this document).
- The initial PCB SWAC of 208 ppb was only used in the risk and surface water evaluations shown in Appendices J and K. For the percent reductions calculated in Section 3 of the 2016 feasibility study report (USEPA 2016b), a value of 92.6 ppb was used as the initial PCB SWAC, and all alternatives were based on this SWAC. This value is close to the 85 µg/kg used in the 2015 draft feasibility study report (USEPA 2015) and only differs based on changes in site area.
- EPA acknowledges there is uncertainty in the analysis of acceptable fish consumption rates. Human health and ecological risk assessment calculations are discussed in Sections 2.33 and 2.34 of this responsiveness summary.

### 2.7.7 Address Concerns Regarding SWAC Calculations

Specific comments or questions were received from five commenters pertaining to SWAC calculations. Some commenters stated that EPA cites various SWACs without clarifying which SWAC was used in the analyses, or it was unclear how the SWACs were calculated. Others said that methods used for estimating post-construction risks are inconsistent with the baseline risk assessments. For each comment or question, a comment summary and response is provided below.

#### a. Comment Summary

The BHHRA (Kennedy/Jenks 2013) estimated risk-based on upper bound sediment and fish tissue concentrations for fish consumption. The same approach was not used in the proposed plan assessment. Different data averaging methods and assumptions were utilized for the different SWAC estimates (site-wide vs. rolling river mile, and SDU-wide).

#### EPA Response

Different methods of calculating SWACs were used as appropriate to the analysis. Site-wide SWACs were utilized to conceptually understand the contamination across the Site as seen in feasibility study report Sections 3 and 4 (USEPA 2016b). SDU comparisons were used to understand how more localized area concentrations were being addressed by the site-wide SWACs. Rolling river mile calculations were deemed to be a more appropriate scale to address the exposure of fish species to contamination as demonstrated in response LSS Dispute Issue 1 (Appendix A of this document).

#### b. Comment Summary

A commenter stated that EPA cites various SWACs, without clear explanation of what is used in which analyses. The different appendices describing SWACs and 95 percent UCLs on those averages include:

- Appendix B: In Table B1-4, the starting PCB site-wide SWAC is listed as 92.6 µg/kg, presumably related to averaging of the values used in the smallmouth bass exposure areas.
- Appendix I: An uncertainty analysis presents five methods to interpolate surface sediment data. The starting PCB site-wide SWACs are presented as a range from 79 to 205 µg/kg. Appendix I also describes methods to find lower and upper 95 percent confidence limits on the SWACs. A confidence limit of 67 to 95 µg/kg on the natural-neighbor method is presented in text and figures.

- Appendix J: In Table J2.3-1a, the starting PCB site-wide SWAC is listed as 208 µg/kg. According to text on Page J-3, this value is a 95 percent UCL of a SWAC. Region 10 does not explain why it changed the Site-wide PCB SW AC from 85 ppb in the 2015 feasibility study report to 208 ppb in the 2016 feasibility study report. This SWAC is inconsistent with recent evidence that supports an even lower SW AC than 85 ppb. No evidence as to how EPA arrived at number is provided.

The commenter stated that the feasibility study report (USEPA 2016b) and proposed plan (USEPA 2016c) do not fully document which methods were used for which analyses; therefore, the findings from these analyses are difficult to understand. It is not always clear whether an average or a 95 percent UCL is being used, and, depending upon what is presented, the apparent benefits of an action can change. The values used in decision making and remedy selection must be clearly articulated.

### **EPA Response**

In response to the specific comments above, EPA provides the following clarification:

- This value is consistent with the site-wide SWACs presented in feasibility study report (USEPA 2016b) Section 3, Figure 3.4-1, which shows a current SWAC of 92 µg/kg.
- Appendix I presents the uncertainty analysis for comparison to the method used in the feasibility study report and does not present actual PCB values in the feasibility study report. This approach is further described in LWG Dispute Issue 1c included in Appendix A of this document.
- The value of 208 ppb was only used in Appendix J and K and was not used in calculations within the main text of the 2016 feasibility study report (Sections 3 and 4 calculations). This value is explained in response to LWG Dispute Issue 1c. How different SWAC values were used is explained in LWG Dispute Issue 1d. Please see Appendix A f of this responsiveness summary or additional information.

Please see ROD Appendix IV Introduction for an explanation of EPA's updated approach for the site-wide SWAC calculation and evaluations used in updated Appendices J and K in the ROD.

### **c. Comment Summary**

One commenter stated that the descriptions of interpolation and averaging methods in Appendix I of the feasibility study report (USEPA 2016b) lack clarity. In EPA's explanation, it presents four very different maps (Figure I-4) of interpolated PCB concentrations in surface sediment. None of the maps are labeled, and minimal legend elements are provided, so the reader is left to wonder about the various methods being displayed. But the title of the figure, "Four Equally Likely Simulated Maps of PCBs," suggests there is a lot that is not known about the sediment condition.

### **EPA Response**

The method known as conditional simulation is described in Section 2.2.2 of the 2016 feasibility study report (USEPA 2016b) with over a page of text, including a flow diagram describing the intermediate steps supported by three technical references available in the scientific literature. Conditional simulation represents the most advanced state of the science in statistical analysis of spatially correlated data for environmental and geological sciences and mining. The algorithms which form the building blocks of the simulation, P-field simulation and natural neighbor interpolation are well documented in the referenced literature.

The comment asks for more detail with regard to the four equally likely contaminant surfaces shown in Figure 4, lamenting the lack of legend information. The figures are designed to avoid clutter that could cloud the purpose of the figures. These figures illustrate that there is a great deal that is not known about the sediment condition by showing that no individual simulated map is of any greater significance than any other of the 100 equally likely surfaces that were simulated. This is the understanding that was intended to be conveyed by the four maps. Contaminant distributions that are consistent with the sample data are varied, yet despite this level of uncertainty, remedial design and SWAC forecasting involves a great deal of averaging, which ameliorates much of the spatial uncertainty, but not all, as can be seen in the subsequent figures documenting the SWAC vs RAL relationships.

#### **d. Comment Summary**

One commenter said that the use of a broad range of percentiles of the contaminant distribution is not an appropriate way to estimate uncertainty in the SWAC. Although there are no statements in Appendix I to indicate that EPA used these estimated uncertainties to estimate post-construction risks or to select the preferred alternative, page 4-9 of the 2016 feasibility study report (USEPA 2016b) main text reads:

*“The analysis showed that for some alternatives, the uncertainty bounds of the post-remedial SWAC overlap the uncertainty bounds of the pre-remedial SWAC. This indicates that there is potentially no remedial benefit for those alternatives because the pre- and post-remedial SWACs are statistically indistinguishable when uncertainty in the SWAC estimates are taken into account.”*

The statement that “those alternatives ... are statistically indistinguishable” is not correct, and suggests that Alternatives B and D were found to not meet the threshold criteria for protectiveness because of the perception that they are “statistically indistinguishable” from Alternative A. The assertion that datasets with wide ranges of concentrations with potentially overlapping confidence limits on the mean are statistically indistinguishable is flawed, and EPA should not use this faulty premise to favor more aggressive remedies. Further, there is a lack of clarity on the reason that Alternatives B and D were considered protective in the draft feasibility study report (USEPA 2015), but not in the 2016 feasibility study report.

#### **EPA Response**

Remedial actions are compared based on predictions of post remedial SWAC which are subject to statistical uncertainty because they are estimated from samples. The sample data are based on a combination of biased and unbiased sampling programs which preclude use of simple statistical methods that require unbiased probability based sampling designs. Under the assumption of positive spatial correlation, biases can be approximately corrected through spatial weighting, and uncertainty bounds can be developed through application of geostatistical models. In the feasibility study report (USEPA 2016b), the standard geostatistical approach based on conditional simulation was applied to data from the Site and resulted in point estimates of the mean (SWAC) as well as the best available 95 percent confidence limits, conditional on the non-probability based sampling design.

Using standard statistical procedures, such as a Student’s T interval or a bootstrap confidence interval when confidence intervals do not overlap, one can draw the conclusion that the means differ with more than 95 percent level of confidence. Equivalently, one would reject the null hypothesis of equal means with a statistical significance of less than 5 percent. When intervals overlap slightly, it is possible that the means differ at the 5 percent level of significance. However, when intervals overlap substantially, such as when an interval captures the mean, one can conclude that the difference in means is not statistically discernable—they are indistinguishable at the 95 percent level of confidence. When

intervals overlap slightly, they may differ at the 5 percent level, but as the overlap increases the level of statistical significance of the difference increases (they become statistically indistinguishable).

EPA could develop specific estimates of the statistical significance of the difference in estimated SWACs for each alternative; however, visual inspection (identifying differences that are clearly discernable practically and statistically) provides a more pragmatic evaluation and identifies differences in SWAC that are well outside the margins of statistical error. It would be irresponsible for EPA to select a remedy that could not be reliably predicted to provide the level of SWAC reduction necessary for risk management. Estimation of the SWAC and its uncertainty bounds is approximate because of the lack of rigorous probability based sampling design, so it would be foolhardy to search for exact levels of statistical significance that themselves are only approximate.

Rather, a more appropriate approach would be to follow up the feasibility study report process with remedial design sampling to verify the geostatistical model and improve spatial resolution of deposit boundaries, to reduce uncertainty in SWAC projections associated with the final design.

#### **e. Comment Summary**

Several comments were submitted that are related to the SWAC evaluation in Appendix J, of the 2016 feasibility study report, as summarized below:

- EPA has a flawed baseline calculation for PCB SWACs of 208 ppb in Appendix J which is in conflict with the 92 ppb used on Figure 3.4-1 in the 2016 feasibility study report. This is an unexplained inconsistency in EPA's methods as none of the text, figures, or tables explain this value.
- Our current understanding is that the EPA value of 208 ppb derived in Appendix J may be completely separate from the value of 205 ppb described in Appendix I, and they are only coincidentally similar. This remains unclear.
- The Appendix J method of calculating site-wide SWACs appears fundamentally flawed. EPA is indicating that the Site was cut into 31 subareas, and a SWAC was "computed" for each subarea. EPA then made the assumption that the SWAC for each subarea was somehow a potentially representative "sample" of the entire Site SWAC, which is clearly an inaccurate and scientifically unsupported assumption. Empirical data collected over 15 years irrefutably demonstrate that the Site has areas with relatively high and low PCB (and other chemical) concentrations, and the SWAC in any given subarea may have little relationship to the overall surface-weighted average across the entire Site. By selecting the concentration from one subarea to represent all post-construction risk estimates for the entire Site, EPA is deciding that all human health and ecological exposures represented by any particular RAO or scenario occur in that one subarea. In other words, while a given BHHRA scenario may assume a person is catching fish from the entire Site, EPA's feasibility study method reduces this assumption to a person catching fish from just one select subarea for the entire exposure period. Additionally, because EPA is using an upper prediction limit (UPL), this person is assumed to consume only fish from an area with comparatively high concentrations.
- EPA indicated they calculated averages within each SDU and then placed those values in its ProUCL software to generate a 95 percent UCL. The method described is technically incorrect because it gives equal weight to river segments (SDUs) with different surface areas. EPA should document the method used clearly in the feasibility study report to support its decision, and EPA

should revise its method because the method indicated is not defensible, especially when it is relied upon by EPA to promise risk reduction for its proposed highly expensive remedial alternatives.

- EPA's selection of the preferred alternative is based upon an overconfidence in its estimated SWACs, which in turn are used to estimate tissue concentrations and the corresponding fish consumption risks. For example, the calculated site-wide cancer risk for Alternative B is  $4 \times 10^{-4}$ , whereas Alternative D is associated with a  $3 \times 10^{-4}$  risk (Tables J2.3-1b and c). Within the uncertainty in the starting SWAC alone, and with regard to the other issues noted, these two numbers are not different from one another, and EPA's selection of its Preferred Alternative is not justified.

### EPA Response

In response to the specific comments above, EPA provides the following clarification:

- The value of 208 ppb was only used in Appendix J and K and was not used in calculations within the main text of the 2016 feasibility study report (Section 3 and 4 calculations) (USEPA 2016b). This value is explained in response to LWG Dispute Issue 1c.
- The value of 208 ppb is not related to the 205 ppb used in Appendix I. The 205 ppb is part of the uncertainty analysis and is only meant to represent the range of values based on different methods.
- EPA's response to this comment is discussed in LWG Dispute Issue 1c (Appendix A of this document).
- The response described is actually the method used in Appendix J to calculate initial SWACs. This method is defended in EPA's response to LWG Dispute Issue 1c (Appendix A of this document).
- EPA's selection of its preferred alternative was not based on a risk – the data found in Appendix J was not used to determine the Alternative but to evaluate the alternatives. The SWACs were evaluated separately for the risk and surface water calculations in Appendices J and K of the 2016 feasibility study report.

Please see ROD Appendix IV Introduction for an explanation of EPA's updated approach for the site-wide SWAC calculation and evaluations used in updated Appendices J and K in the ROD.

### f. Comment Summary

One comment stated that the feasibility study report and proposed plan do not fully document which methods were used for which analyses and, therefore, the findings from these analyses are difficult to understand. It is not always clear whether an average or a 95 percent UCL is being used, and, depending upon what is presented, the apparent benefits of an action can change. The values used in decision making and remedy selection must be clearly articulated. The commenter further stated that in Appendix J, post-construction rolling river mile and SDU average calculations are presented, but they appear to have no relationship to the SWAC calculations described in Appendices B or I (PRG Development and SWAC Uncertainty, respectively) because the data and methods used in all of these appendices (B, I, and J) are ambiguous. The phrase "These sediment concentrations were input into the FWM ... " (in the first paragraph of Section J2.3) apparently refers to site-wide SWAC values, but it does not specify whether the concentrations are derived from a straightforward application of the nearest-

neighbor method or whether the uncertainties were derived from conditional simulations which were used to derive a UCL for the SWAC that was used for the risk assessments.

### **EPA Response**

The method used to develop SWACs used in development of technologies and costs in feasibility study report Sections 3 and 4 are presented in Appendix D of that report (USEPA 2016b). Appendix D discusses the development of site-wide SWACs (Section D1), as well as SDU and rolling river mile SWACs developed to facilitate the evaluation of protectiveness and long-term effectiveness in the feasibility study report. The same method was used to develop the site-wide sediment SWACs presented in Appendix B of the feasibility study report. Appendix I presents an uncertainty analysis that is not used in any additional calculations. Appendices J and K use alternative methods to evaluate risks to environmental and human health. These alternative methods are useful as supporting material and do not contradict the methods presented in the feasibility study report. Please see the replies to the above comments b, c, and d in this subsection for additional clarification on Appendices I, J, and K.

### **g. Comment Summary**

One commenter said that an unstated assumption is that the 31 subareas defined by EPA are a statistically valid way of dividing the Site. EPA clarified that the subareas are based on SDUs, which EPA states were devised to specifically identify the areas of highest COC concentrations on a rolling river mile basis. Many other methods could be used to define subareas of the Site, each of which would yield different statistics than the one EPA selected. Further, EPA has created an explicitly bimodal distribution of subareas, with some subareas focused on the highest observed concentrations (the SDUs) and remaining subareas focused on the lowest observed concentrations. This method is biased and inherently inaccurate for subsampling Site SWACs, and consequently, it is likely that other less biased and more scientifically supportable subsampling methods would produce a lower overall SWAC estimate.

### **EPA Response**

EPA performed the approach as summarized by the commenter and made assumptions based on transparent and data supported rationale to perform a comparative evaluation among the alternatives presented in the feasibility study report (USEPA 2016b). The commenter does not provide any supporting information revealing how this approach is biased and only presents assertions of bias on the approach and speculates on the outcome of these assertions.

## **2.8 Habitat**

### **2.8.1 Prevent and/or Mitigate Loss of Habitat**

#### **Comment Summary**

Nineteen personal comments were received that focused primarily on a desire to prevent habitat loss and to restore lost habitat (paid for by the PRPs) where prevention of loss was not possible. Some commenters believed that preservation of habitat should have been included in the proposed plan.

Representative comments include:

- “Restoration of any lost habitat needs to be a requirement of the final remedy. The proposed plan refers to restoration, and this restoration must comprehensively include actions following removal actions.”

- “Ensure restoration of all lost habitat and of water quality, such that fish are edible without an advisory.”
- “We fully support a clean-up plan that makes habitat viable for native fish—migratory and resident. EPA should also consider how we can connect the cleanup requirements to the different limiting factors affecting listed salmon populations and other native resident fish. It seems that the ecological Remediation Action Objectives are solely focused on disrupting the accumulation of Contaminants of Concern up the food chain. This is important, especially from a human health perspective, but seems to ignore the salmon recovery needs for Willamette River populations. The Plan should consider potential impacts and benefits to juvenile and migrating salmon. The clean-up requirements should incorporate the in-depth knowledge of habitat needs throughout the North Reach of the Willamette River, especially for juvenile salmon. This includes ensuring consistency between clean-up option selection, clean-up project design and mitigation, and the Natural Resources Damages process already underway. Mitigation for the negative impacts of cleanup activities on those species should begin immediately. Ideally, the cost, community acceptance, and long-term effectiveness criteria would all consider options that help meet the multiple ecological and habitat restoration needs for this reach of river.”
- “More emphasis on upland habitat recovery and restoration.”
- “Protect shorelines, nearshore habitat, and communities residing nearshore.”
- “Restoration of habitat. Wildlife do not have the luxury of avoiding the 10-miles of the lower Willamette River. It is an important part of the watershed and serves as a migration pathway and habitat for several important endangered or declining species: Chinook salmon, steelhead, Lamprey eel and white sturgeon. Adults migrate upriver to spawn and juveniles migrate down river to the Columbia and ocean. Since all species require habitat, especially off-current or shallow water habitat for rest, feeding and to avoid predators, it is vitally important to restore habitat as soon construction occurs. MNR, capping and dredging will disturb and degrade habitat by reducing diversity of vegetation and other amenities, so restoration of vegetation and other habitat amenities needs to occur during construction, not only as part of the NRDA program. The funding for restoration of habitat should be fully paid for by Potentially Responsible Parties.”
- “There is no real plan for the restoration of lost habitat.”
- “The plan should protect and enhance existing fish and wildlife populations and habitats. Cleanup actions should reconnect existing and potentially favorable habitats. 4. Cleanup and management of contaminated materials should support restoration and protection of processes that maintain watershed health – normative hydrology, functioning physical habitat, improved water quality, and healthy native biological communities.”
- “Habitat restoration in perpetuity fully paid by PRPs. Restoration of any lost habitat needs to be a requirement of the final remedy. The proposed plan refers to restoration, and this restoration must comprehensively include actions following removal actions.”

### **EPA Response**

EPA understands the commenters’ concerns about habitat loss resulting from the cleanup. The feasibility study described the role that Section 404 of the Clean Water Act and Oregon mitigation regulations have as action-specific ARAR for the Portland Harbor remedy at page 2-5:

- “Section 404 of the Clean Water Act regulates the discharge of dredged or fill material into navigable waters, with the exception of incidental fallback associated with dredged materials. This ARAR is applicable to cleanup actions in navigable waters of the Site that will discharge dredged material or capping material into the Willamette River or adjacent wetlands, including the specification of in-river disposal sites. The alternative evaluation process includes considerations of the Clean Water Act hierarchy to avoid or minimize loss of aquatic habitat or function, but if a loss was deemed unavoidable, mitigation will be included as part of the alternative. A 404(b)(1) analysis of the remedial alternatives is provided in Appendix J [L]. The final assessment of loss and determination of mitigation will be made during remedial design. In addition to Section 404 of the Clean Water Act, ORS 196.825(5) and applicable substantive mitigation rules found at Oregon Administrative Rules 141-085-510, 141-085-680, 141-085-0685, 141-085-0690, 141-085-0710, and 141-085-715 provide requirements for mitigation for the reasonably expected adverse effects of removal or fill in a project development in waters of the state, including in designated Essential Indigenous Anadromous Salmonid Habitat.”

Similarly, the remedy must comply with the substantive requirements of the Endangered Species Act, which protects salmon and other species that may be present at the Site. This issue is further detailed in the feasibility study report at page 2-4 (USEPA 2016b). Section 7 of the Endangered Species Act requires that actions authorized by federal agencies may not jeopardize the continued existence of endangered or threatened species or destroy or adversely modify critical habitat. ROD Section 15.2.3 discusses compliance with ARARs.

Appendix L of the feasibility study report describes the impact avoidance and minimization measures that would be implemented during cleanup activities to protect aquatic habitat. All alternatives analyzed included measures to minimize habitat impacts, particularly where dredging and capping was proposed for the shallow region of the river as described in more detail below. A draft programmatic biological assessment was drafted and shared with U.S. Fish and Wildlife Service and National Marine Fisheries Service for review and comment. Their input on appropriate consideration of impacts and measures to mitigate these impacts is reflected in the proposed plan (USEPA 2016c) and the ROD. During remedial design, avoidance and minimization measures will be developed according to the specific conditions of each cleanup area, and further review and coordination with National Marine Fisheries Service and the U.S. Fish and Wildlife Service will occur.

As described in the feasibility study report Appendix L, there would be unavoidable short-term impacts on habitat for fish and other aquatic species in areas where dredging, capping, or ENR would occur. These short-term impacts are primarily associated with the disturbance to the benthic community from these activities in nearshore areas. Following the cleanup activities, a mix of rounded small gravel, also known as “beach mix”, would be placed over the surface of the remediated river bottom, where appropriate. Beach mix provides appropriate substrate to allow the benthic community to recover, which is expected to take a few months. Removing the contamination from the aquatic food chain through dredging, capping, and ENR will provide substantial benefits to aquatic species, including federally listed salmon.

To avoid or minimize potential permanent adverse impacts on aquatic habitat and river bank habitat resulting from the cleanup there are several measures proposed. These measures include any area assigned dredge/cap in the shallow region will first be dredged to the depth of the cap, and any area assigned dredge only will be backfilled to existing grade with a beach mix cover to leave the appropriate

water depth and shoreline slope to maintain shallow water habitat important for many species, including juvenile salmon. In addition, riparian vegetation, bank layback, large woody debris, and other components of shoreline habitat may be provided where possible following construction of such areas. Habitat aspects of other depth zones would also be considered, where appropriate. These measures would be developed in coordination with National Marine Fisheries Service, and U.S. Fish and Wildlife Service.

Where unavoidable temporary or permanent loss of habitat may occur from the cleanup, specific requirements for compensatory mitigation would be developed during remedial design. Compensatory mitigation projects could entail converting existing upland habitat to shallow water habitat, reducing bank slope angles and adding riparian vegetation, and/or re-connecting to off-channel habitat. Such projects likely would require the appropriate sand/gravel substrates, shallow slopes, and shoreline complexity to benefit salmon and other aquatic species. These projects would likely be constructed in the lower Willamette River and/or the Columbia River, with a preference for projects to be undertaken as close to the impacted area as possible.

Restoration of habitat impacts site-wide as a result of releases of hazardous substances and petroleum will be addressed by the Natural Resource Trustees, which will include habitat restoration work above and beyond compensatory mitigation that EPA can require under the Clean Water Act 404(b)(1) and Endangered Species Act.

## 2.8.2 Revegetate to Promote Habitat

### Comment Summary

Twenty-three comments were received that focused on revegetation. All but two were part of form emails and stated

- “Habitat restoration following remedy construction needs to be a required element in the R.O.D. Aquatic habitat that is disturbed by the remedy must be restored and the full cost paid by the PRPs. When nearshore and intertidal habitat has to be removed, it must be replaced and replanted with SAV [submerged aquatic vegetation] that thrives.”

The remaining two comments had more detailed suggestions for revegetation. They included:

- “Financially offer responsible parties to reduce dollars spent by offsetting carbon emission with carbon sequestering. The federal farm bill has money for public and private lands to use federal funds to kick start carbon forest which equals phytoremediation and a hopeful future for all living creatures that inhabit the Willamette River sites.”
- “I petition and request:
  - 1. A phytoremediation and carbon sequestering plan be put into Portland Harbor Superfund Clean Up plan and to be implemented in all toxic affected areas along the Willamette River bank. What’s important is the type of trees, shrubs and flowers, (including but now exclusive to native plant life) incorporating all aspects of companion planting and the use of new science (year-round habitats developed from Bee Baseline Portland Project) and information from the book written by Kristen Ohlson “*The Soil Will Save Us*,” regarding how to sequester/create a carbon soil/forest. I have a detailed list of trees, shrubs and flowers and how each plant will

best serve present and future hope for clean soil, water and air along the Willamette River.

- 2. Financially offer responsible parties to reduce dollars spent by offsetting carbon emission with carbon sequestering. The federal farm bill has money for public and private lands to use federal funds to kick start carbon forest which equals phytoremediation and a hopeful future for all living creatures that inhabit the Willamette River sites.
- 3. Best trees, shrubs and flowers needed are a variety and what's required a minimum of a 120 total. Here are a few plants listed here. Cotton Wood (Both male and female) Ponderosa Pine, Madrone, Pink and White Crepe Myrtle, Witch Hazel, Doug Fir, Sitka Spruce, Black Hawthorne, Vine Maple, Poplar, Elm, Forsythia, Daphne, Crocus, Aster, Germander, Geranium, Ribes, White Rock Rose, Potentilla, Rosemary, Fennel, Oregano, Thyme, Sky Pencil Holly, Oak Leaf Hydrandea, Snow Berry, Fushia Rock Rose, Crocosmia, Camilla Japonica, Winter Sweet, Black and Blue Salvia, Floribunda Yellow Rose, Salvia Farinacea, Basswood Lynden, Lavendula, Lavender, Heather, Anenome, Abelia bush, Bacopa, Curly Willow, Blue Russian Sage, Hibiscus, Ceanothus, Ivory Silk Lilac Tree, Mock Orange Tree are a good start to what can really transform the toxic past into a heroic present and future. Thank you and Good Luck. I am available if you have any questions. I am happy to help anyway I am able. Thank you, thank you, thank you for the health and happiness of all living creatures in Portland.”

### **EPA Response**

As described in Appendix L of the feasibility study report (USEPA 2016b), aquatic and river bank habitat impacted by the cleanup will be mitigated by best management practices and on-site measures. These measures include:

- Following dredging in shallow water areas (0 to 20 feet from ordinary low water), backfill would be used to restore the existing (pre-dredging) elevation to avoid loss of shallow water habitat.
- To offset permanent and/or temporal loss of habitat functions from dredging and capping in shallow water areas and as on-site mitigation, following dredging and capping in shallow water areas, slope would be laid back to as close the existing slope as practicable given site-specific conditions.
- To further offset permanent and/or temporal loss of habitat functions from dredging and capping on river banks and as on-site mitigation, after soil removal on river banks, river bank slopes would be laid back to as close as a 5H:1V slope as practicable given site-specific conditions.
- Capping in shallow areas would specify dredging of an equivalent cap thickness prior to placement to allow for a net zero bathymetry change and avoid loss of shallow water habitat.
- Engineered beach mix layer, consisting of rounded gravel typically 2.5 inches or less would be applied to the uppermost layer of all caps and dredge leave surfaces in shallow areas. This layer would provide appropriate substrate habitat for colonization by benthic organisms. Beach mix would not be applied to leave surfaces consisting of sand unless required due to changes in

hydrodynamic conditions following remedial activities. In addition, if beach mix is placed over riprap armoring, monitoring would be required to determine whether the site-specific conditions are conducive to maintaining the beach mix habitat layer over the riprap. If monitoring or site-specific modeling demonstrate that a sand/gravel surface can be maintained long term, this may be considered by EPA when determining if the compensatory mitigation proposed during remedial design is adequate.

- Vegetation would be incorporated into caps placed on river banks where possible such as in off-channel areas that are not prone to erosion and with less steep slopes.

Vegetation appropriate for the riparian habitat would likely include willows, cottonwoods, and other native plants that control erosion and provide wildlife habitat. Monitoring may include ensuring invasive species are controlled while native species take hold in these areas. Submerged aquatic vegetation is expected to colonize naturally once the sediment contamination is remediated and appropriate substrate is restored in nearshore areas. Please see the ROD for more details on river bank and nearshore design considerations.

Phytoremediation was evaluated as a remedial technology and screened out in the first step of screening. As indicated on Table 2.4-1 of the feasibility study report, phytoremediation and other in-site biological treatment technologies are not considered feasible to implement because some contaminants are either not biodegradable (particularly heavy metals) or are very persistent in the environment (such as dioxins/furans, PCB, and pesticides).

In-situ treatment with activated carbon and other materials, is sometimes referred to as “sequestration,” as identified in Tables 2.4-1 and Table 2.4-2 of the feasibility study report. This was retained as an in-situ treatment technology process option and will be further evaluated during remedial design when detailed plans for the cleanup at specific areas are developed.

EPA may also support carbon sequestering and other technologies to reduce the carbon footprint of the cleanup, in accordance with the green remediation approach. This could be implemented as part of the Green Remediation Plan for reducing environmental impacts during the cleanup, but is not a remediation technology to address the contamination itself.

### 2.8.3 Ensure Caps Do Not Reduce Habitat through Flood Rise

#### Comment Summary

Two comments were received on shallow areas, as they relate to habitat:

- “In order to minimize impacts to the aquatic environment and flood rise, EPA has determined that all cap areas in the shallow regions need first to be dredged to a depth equal to the cap thickness and any dredge areas will be backfilled to pre-dredge grade. EPA provides no explanation as to why flood-rise considerations are any greater in shallow regions than in other regions of the river. Its focus should be on aquatic environment and slope stability. The ultimate post-cleanup elevations in shallow regions should be designed to establish the best aquatic habitat and bank stability possible. There is no reason for EPA to strictly prescribe that shallow region elevations should remain unchanged.

There are many unique features of the near-shore shallow region offshore of Gunderson, largely as a result of fill and regrading that occurred decades ago, long before Gunderson's ownership.

EPA needs to provide more flexibility in terms of the possible design of dredging and capping in these near-shore areas.”

- “Does the plan allow the City to retain adequate flexibility to mitigate for future floodplain impacts in the North Reach of the Willamette unrelated to Superfund? For example, over reliance on capping or leaving excessive amounts of contamination in place, could result in a situation in which there may not be adequate opportunities available to mitigate for future industrial development activities within the floodplain in the North Reach. This could result in a situation where either development is precluded or in which mitigation costs increase because mitigation has to be done outside the North Reach rather than in close proximity to the actual impact area.”

### **EPA Response**

Aquatic habitat and flood rise/adverse floodway impacts are two significant ARAR considerations for using and designing caps in the Willamette River. Balancing of dredge and fill volumes to the maximum extent practicable is assumed to limit flood rise throughout the Site. Also, a goal of the cleanup will be to not adversely affect floodplain capacity or cause floods to encroach upon new areas by increasing base flood elevations of the Site. Therefore, the cleanup should not impact the city’s future decisions on floodplain developments and mitigation options. See Section 2.19.11 of this responsiveness summary for more response on flood rise issues.

A flood rise analysis was undertaken on the remedial alternatives in the feasibility study to generally assess the feasibility of using caps at the Site. Impacts on aquatic habitat were considered for the shallow region as identified in Section 3.4.7.5 and Appendix L of the feasibility study report (USEPA 2016b). More detailed modeling will be conducted during remedial design on both an SMA and site-wide scale to demonstrate that remedial actions do not result in unacceptable flood rise.

The Clean Water Act Section 404 requires avoiding or minimizing impacts to the aquatic environment, and EPA is coordinating with the NMFS on measures to protect habitat for listed species, including juvenile salmon, which depend on shallow water habitat at the Site. In its comments on the proposed plan (USEPA 2016c), NMFS has strongly recommended limits on conversion of shallow water habitat to “submersible lands” (areas that would not be constantly submerged). To that end, NMFS recommends “reducing the repose of shorelines and removal of streambank fill to expand the floodway and active channel” (Section 4).

EPA intends to follow the recommendations of the NMFS, to the extent feasible, to avoid or minimize impacts on shallow water habitat. During remedial design, a detailed evaluation of area-specific conditions would be conducted. The ROD allows for flexibility in selection and design of remedial technologies based on information collected during remedial design. That said, EPA reiterates the goal of avoiding or minimizing effects on aquatic habitat, particularly to listed species and their critical habitat in compliance with the Clean Water Act and the Endangered Species Act.

## **2.8.4 Consider Habitat Restoration**

### **Comment Summary**

One comment was received from the Audubon Society that addressed the topic of habitat restoration. It stated in part:

- “The Clean-up Plan and F.S. should address the recent Biological Opinion released by National Oceanic and Atmospheric Administration Fisheries regarding the National Flood Insurance

Program. We question whether compliance with the BiOp should be considered an ARAR. Does the plan comply with the specific terms of the BiOp such as avoiding construction in the floodway, fully mitigating for construction that adversely impacts salmonid habitat both in the river and on adjoining floodplains, and providing balanced cut and fill for to compensate for any filling in the floodplain?

The Plan should include a much clearer description of the natural resource mitigation that will be required to compensate for habitat loss and other loss of natural function resulting from the implementation of the remedy. The discussion of natural resource mitigation that will be required as a result of implementation of the remedy (as opposed to mitigation that will be required under NRDA to compensate for impacts of contaminants on wildlife and other natural resource values), is cursory. EPA should more clearly define the local, state and federal laws under which mitigation will be required. EPA should include in this estimate, mitigation that will be required under NMFS' NFIP Biological Opinion. It should also consider requirements under local regulations such as the city of Portland Greenway Code."

### **EPA Response**

The NFIP Biological Opinion is not an ARAR for the CERCLA cleanup. First, it does not meet the definition of an applicable or relevant and appropriate requirement as defined in the NCP. Secondly, the NFIP Biological Opinion relates to Federal Emergency Management Agency responsibilities in implementing the flood insurance program and sets forth requirements for local communities regarding how to manage floodplains and development within a floodplain.

Response to Comment 1a: The CERCLA cleanup, however, must meet the substantive requirements and goals of Federal Emergency Management Act regulations at 44 CFR § 9, which set forth the responsibilities to implement existing Executive Orders on management of floodplains and protection of wetlands. See EPA's ARARs tables (25 a through c) in the ROD Appendix II. The substantive Federal Emergency Management Agency regulations are relevant and appropriate for assessing impacts, if any, to the floodplain and to flood storage capacity from the response action.

As the commenter noted, while natural resource damage restoration is not in EPA's purview, the cleanup will need to comply with the substantive requirements of the Clean Water Act, Endangered Species Act, and state regulations related to compensatory mitigation that may be required due to unavoidable loss of habitat, if any, resulting from the cleanup EPA's feasibility study alternatives analysis as informed by the Flood Rise and Clean Water Act Section 404(b)(1) analyses in Appendices P and L, respectively, and the final selected remedy, incorporates requirements for how dredging and capping designs must result in no rise of the bottom of the river and measures that will be taken to avoid or minimize impacts to habitat from the cleanup. See the ARARs tables (ROD Appendix II) for a list of all the federal and state laws and regulations that relate to floodplain and habitat mitigation.

The ROD describes various mitigation measures that will be required for cleanup actions taken in specific areas of the river, with a preference for these to be conducted on-site whenever possible. EPA is and will continue to coordinate with NMFS on measures to protect habitat for listed species. Because the contamination is located in the floodway itself, it is not possible to avoid the floodway when conducting the remedial "construction" activities associated with the cleanup. During remedial design, the extent of unavoidable loss of habitat, if any, will be determined, and specific compensatory mitigation requirements will be developed in coordination with NMFS and state resource agencies.

EPA will prioritize mitigation measures to be taken on site, or as close to the area of impact as possible, which will be constituted primarily with shallow zone and river bank areas critical to Endangered Species Act species. Where necessary, off-site mitigation work may be needed due to lack of available areas to conduct the on-site work. EPA will also seek to work with private companies to obtain approval from the USACE and Oregon Department of State Lands for mitigation banks under Clean Water Act 404 close to or within the Site such that parties unable to fully mitigate on site have a fully approved option to remedy habitat impacts as quickly as possible to minimize temporal impacts to the Lower Willamette ecosystem.

Appendix G of the feasibility study report (USEPA 2016b) explains how such mitigation costs were calculated from the average cost of other sediment cleanup projects in the Pacific Northwest, including the Lower Duwamish and Commencement Bay (Hylebos). Mitigation costs for each project were escalated to the base (current) year of the estimate for averaging.

## 2.9 Alternative Evaluation

### 2.9.1 Explain Deficiencies in the Alternative Evaluation Process

#### Comment Summary

Comments were received from about a dozen sources, including businesses, City of Portland, CAG, Swan Island Lagoon Group, and Portland Audubon Society that related to the evaluation process for alternatives in the feasibility study.

Several of the commenters stated that the evaluation of alternatives is deficient for one or more of the following reasons:

- EPA should evaluate sustainability of the alternatives.
- Alternative I relies too heavily on ICs to prevent exposure; ICs do not protect ecological receptors and are potentially ineffective against human exposure as well.
- There are numerous problems with determining that B, D, E and I are not protective and a specific example is the evaluation of BEHP evaluation around Swan Island Lagoon.
- EPA's alternative evaluation is flawed because it is based on an inaccurate CSM, there is an error with the cleanup area, it ignores recent data, and EPA used an over simplified approach.
- The evaluation did not include site-specific factors and does not consider implementability challenges.
- The quantitative bases to compare rates and levels of risk reduction lack reason.
- Risk reduction from fish consumption is not apparent and attainment of cleanup goals is not clearly evaluated.
- EPA has underestimated the effectiveness of Alternatives B and D.
- The statistical methods used to evaluate alternative effectiveness are unclear and technically suspect or flawed.

- EPA did not evaluate PTW treatment and application of activated carbon equally under all alternatives.
- Does not included a quantitative or detailed short- or long-term effectiveness evaluation.
- Cost and cleanup benefit of alternatives not fully evaluated in the feasibility study.

Many commenters disagreed with the conclusion of a specific alternative's protectiveness and expressed confusion as to why some alternatives were determined not to be protective. Additionally, some suggested that a more robust evaluation of alternatives needs to be conducted, which may include supplemental analysis or modeling. The maps in the proposed plan do not show the remediation area extending to the back of the Swan Island Lagoon. The preferred alternative is clearly not better than the other alternatives.

The CAG and Audubon request that Alternative G or G Modified be selected as the remedy and that protecting human health (including by addressing frequently used portions of the Site) and the environment is a priority. Many commented that the protectiveness analysis for some alternatives was confusing or incorrect. PTW should be removed due to its toxicity and to prevent future releases. Alternative G should be modified to include more dredging, treating more shoreline and benthic risk areas, revisit navigational restrictions, and reduce the schedule for implementing the remedy.

The Swan Island Group commented that an optimized remedy for Swan Island Lagoon has been developed and accounts for risk reduction associated with ENR. The optimized remedy would cost less to implement than the preferred remedy and would achieve equivalent risk reduction. EPA should only require treatment when contamination contributes to known risks. It is unclear what assumptions were used when estimating residual contaminant concentrations and risks.

The City of Portland requested that, after cleanup has been completed in a small area that people frequently use, EPA should evaluate the cleanup's performance.

### **EPA Response**

The alternatives analysis in the feasibility study and as supplemented to include Alternative F Modified complies with the NCP requirements in 40 CFR § 300.430(e). The development and evaluation of alternatives sufficiently reflects the scope and complexity of the site-wide remedial action under consideration and the site problems being addressed. The CSM complies with EPA guidance and is based on data collected by LWG under EPA oversight. The alternative evaluation included models and various analysis tools that were appropriate for evaluating the alternatives under the first seven criteria.

Based on consideration of the requirements of CERCLA, the detailed analysis of remedial alternatives, and public comments, EPA has selected Alternative F Modified as the final remedy. Sections 11, 12, 13, and 14 of the ROD describe the selected alternative and justification for selecting Alternative F Modified as the remedy. The ROD contains the comparative analysis of the alternatives with Alternative F Modified, including the evaluation of the overall protectiveness of Alternative F Modified. The selected remedy is more protective than Alternative I because it is more permanent and Table 22 of the ROD shows the quantitative increase in the number of meals, which correlates with an increase in the area being dredged. Alternative F Modified addresses all ecological risk upon completion of construction. Immediately after construction of the selected remedy, it is estimated that wildlife will be able to safely consume prey from within the Site since all non-cancer risks on a site-wide scale will be addressed. It is

estimated that BEHP will be at a HQ of 5 at a river mile scale and 3 at an SDU scale, very close to the target of 1 and well within potential calculation variances.

The evaluation in the feasibility study was based on post construction sediment concentrations rather than long-term projections due to the uncertainty in any long-term projections of sediment concentrations and associated risk to human health and the environment. Implicit in this approach is the assumption that alternatives that have a larger remedial footprint will achieve the remedial action objectives established for the Site in a shorter time frame than alternatives with a smaller footprint as they rely less on MNR, this assumption is supported by the updated T=0 charts presented in Appendix IV of the ROD, which show incremental reduction in risk over river mile segments for the RAOs. A supplemental analysis, using SEDCAM to evaluate MNR trends of average PCB concentrations for each alternative post-construction, is included in Appendix IV of the ROD. This analysis helps show the protectiveness of each alternative.

After clean-up levels and RAOs are achieved, the long-term effectiveness of the remedy will be monitored. The ROD describes monitoring requirements in Section 14.2.7. Additionally, the expected cleanup outcomes/performance from Appendix J of the feasibility study report (USEPA 2016b) are updated for the selected remedy and included in Appendix IV of the ROD.

EPA disagrees with the statement that EPA determined that Alternatives B, D, E and I are not protective, with a specific example being a BEHP evaluation around Swan Island Lagoon. In fact, Alternative I was the preferred alternative in the proposed plan (USEPA 2016c). EPA also concluded that Alternatives B and D were protective of human health because ICs can be set in place to ensure protection until such time as cleanup levels are achieved. However, since ICs cannot be placed to ensure protection of the ecological receptors, EPA concluded that these two alternatives were unlikely to be protective of the environment because MNR would not occur in a reasonable time frame. The determination was not made solely based on benthic risk but rather on a more broad-based evaluation consistent with EPA guidance. Consistent with the NCP, overall protectiveness draws from assessments of the other criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs. An uncertainty analysis presented in Appendix I of the feasibility study report was considered as well. Additional discussion of effectiveness is included in Section 2.19 of this responsiveness summary.

Based on recommendations from the NRRB/CSTAG (see NRRB/CSTAG comment on Remedy Performance, p. 5), EPA performed an uncertainty analysis of each alternative to determine the likelihood that the alternative would be significantly different from the No Action alternative. This analysis was presented in Appendix I of the 2016 feasibility study, and the conclusion was that Alternative B post-construction SWACs were statistically indistinguishable from the No Action alternative and that the post-construction SWACs for Alternative D were still within the margin of error relative to no action. Since the No Action alternative was deemed to not be protective, EPA determined that Alternatives B and D are also not protective since Alternative B was statistically indistinguishable from the No Action alternative, and Alternative D was only slightly better for PAHs and PCBs (DDx RALs for Alternative D were also statistically indistinguishable from the No Action alternative).

For further details regarding the evaluation of Alternatives B and D, refer to LWG Dispute Response 1a (Appendix A of this document).

Alternative C was eliminated based on:

- The small incremental increase in quantities of dredge and borrow materials between Alternatives B and C.
- The relatively small incremental decrease in focused COC concentrations when compared between Alternatives B and D or C and D.
- The differences between Alternatives B and C include only a 0.1 percent increase in overall acres remediated with only a corresponding average 9 percent reduction of focused COC concentrations in surface sediment.

It was concluded that Alternative C was not distinctly different from Alternative B and therefore it was eliminated.

Some comments describe generally that the evaluation of alternatives is incomplete and fails to meet requirements of CERCLA or the NCP (such as evaluation of effectiveness). However, since the commenters did not provide specific examples, EPA cannot provide a response.

One commenter recommended a multi-objective decision analysis, which is a benefit analysis tool. Although such a tool can be informative, it was not used at the Site and is not required to be used by CERCLA or the NCP. For this Site, data gathered for the remedial investigation and by other parties was used to evaluate the distribution of COCs in sediment, surface water, and upland media in order to identify the areas where remediation is necessary. Additional monitoring will be conducted prior to designing the remedy in order to incorporate changes in site conditions and will allow flexibility in the design.

Regarding comment on an optimized remedy for Swan Island Lagoon and accounting for risk reduction associated with ENR, the back portion of Swan Island Lagoon was assigned a no SDU technology assignment under Alternative I; therefore, the remediation foot print did not extend to the back portion of the lagoon. The proposed plan did not quantify risk reduction at Swan Island Lagoon due to ENR. This underestimate of risk reduction will be balanced in the ROD discussion with the addition of a higher end risk reduction estimate from ENR, along with a low end estimate to bracket the likely risk reduction outcome of ENR. During the remedial design for Swan Island Lagoon, site-specific factors and risk reduction due to ENR will be further assessed. BEHP exceeds its cleanup level around RM 8 and 9.5. The remedial design for the property will use pre-design monitoring data and flexibility to ensure the appropriate remediation technology is used to achieve protectiveness.

With regards to EPA fully evaluating the cost and cleanup benefit of the alternatives, EPA has included a discussion and presentation of cost-benefit of the alternatives in the ROD Part II, conditional simulation was used to evaluate SWAC uncertainty. The method is further described in Section 2.2.2 of the feasibility study report. Appendix I of the report includes a discussion of the analysis.

EPA did not evaluate PTW treatment and application of activated carbon equally because EPA is not requiring all PTW be treated in-situ. For example, PTW that cannot be reliably contained will be removed through dredging or excavation.

With regards to assertions that the statistical methods used to evaluate alternative effectiveness are unclear and technically suspect or flawed, conditional simulation was the statistical analysis used to

evaluate SWAC uncertainty and is described in Section 2.2.2 of the feasibility study report. Appendix I of the feasibility study report also includes a discussion of the analysis.

In response to the comment that EPA should evaluate sustainability of the alternatives, the CERCLA statute and the NCP set out the requirements for selecting CERCLA remedies at Superfund sites and evaluating sustainability specifically is not provided for in the regulation.

## 2.10 Data Issues

### 2.10.1 Use Newer Data to Design the Remedy

#### Comment Summary

A total of 192 comments were received that stated that EPA was using data that were too old. A little more than half were received in the form of a multi-comment postcard that said:

- “(The plan) relies on data that is more than 10 years old.”

The remaining comments were personal comments and echoed that concern. Many also stated that they believed the river was recovering naturally and that additional data should be collected before cleanup decisions were made.

Representative personal comments include:

- “I'm skeptical about a plan that is based on 10 year old data. Things have changed in the last 10 years!”
- “I know making a plan can take time but in 12 years a river can change a lot and with the newer laws restricting what goes into the river the river has had a chance to clean itself naturally. If there is updated data I would urge you to look at that and consider a less extreme and costly plan.”
- “EPA's plan is based on old information. Since their original data were collected in 2004, studies show that the contaminate levels in the Willamette River have actually improved. This restoration was done naturally...”
- “I find it stunning that the plan to clean up Portland Harbor relies entirely on data from eight and twelve years ago while ignoring data from only two years ago. The more recent data shows that almost half of the contaminants that were in the water have already been eliminated by letting nature run its course.”
- “(EPA) could have been completing tests over this time frame and seen that things are changing for the better, but they haven't. Why is that? It's imperative that all options are considered before moving forward with EPA's unnecessary and expensive proposal to clean the river.”
- “This plan is based on old data that EPA collected in 2004 and 2008. In 2014, experts studying the Willamette River found that the river is recovering. Through natural restoration, there has already been a 40 percent reduction of contamination in the water. EPA has entirely ignored this data to focus on a drastic plan that would make the river inaccessible for years.”

- “I think it’s good to be skeptical of an EPA plan that utilizes data from 2004. That’s twelve years ago. The river is constantly moving and changing. Current studies have determined there to be a minimum of a forty-percent reduction in the contamination levels in the river since 2004, and we should not disregard the findings. Why dig up a river and possibly create more contamination if it’s taking care of itself? Maybe things have settled, maybe there is contamination that has cleared up through natural means, but things have certainly changed for the better and disrupting that process will create problems.”

### **EPA Response**

The Portland Harbor remedial investigation report (USEPA 2016a), feasibility study report (USEPA 2016b), and June 2016 proposed plan (USEPA 2016c) were based on an extensive site characterization that included thousands of surface and subsurface sediment samples, hundreds of pore water and surface water samples, and multiple rounds of biota sampling and physical sampling activities, including sediment profile imaging and bathymetric and side scan sonar surveys. Four rounds of sampling targeting a range of media were performed by LWG between 2001 and 2008. Additional sampling utilized to support EPA’s proposed cleanup were collected by individual parties between 1997 and 2011, including additional sediment data collected between 2008 and 2011. Finally, tissue sampling that focused on individual smallmouth bass and PCBs was performed in 2007, 2011, and 2012.

EPA utilized the 2007-2012 smallmouth bass fish tissue samples to evaluate declines in fish tissue concentrations associated with natural recovery. Based on the results of this analysis, presented in Section 3.6.1.3 of the feasibility study report, EPA concluded that the sample size, limited number of time points, and inconsistency in sampling methodology preclude a meaningful, statistically valid determination of a trend in fish tissue concentrations. The 2007 and 2012 fish tissue data may serve as a baseline for future evaluations of fish tissue PCB concentrations; however, baseline fish tissue data for other bioaccumulative contaminants will need to be established through the remedial design process.

EPA acknowledges that the majority of site-specific data were collected prior to 2008. However, EPA believes that the data are sufficient to accurately characterize the nature and extent of contamination, assess risks to human health and the environment, evaluate remedial action alternatives in the feasibility study, and serve as the basis for selecting a remedy for the Site. Also, see response in Section 2.10.2. for further response on newer data.

Any uncertainties in the data or changes in site conditions will be addressed through focused remedial design sampling activities at the Site. Remedial design sampling data will be used relative to the decision tree in the ROD to refine the footprint of areas that will be targeted for capping, enhanced natural recovery, and in-situ treatment and to refine the volume of material that will be targeted for removal through dredging and excavation. In addition, long-term monitoring will be performed to monitor the effectiveness of the remedy to achieve the remedial action objectives established for the Site. Data on contaminant levels in all media will be used for multiple purposes such as to determine if natural recovery is taking place as expected or if any additional actions are required to achieve the cleanup goals on the planned timeline, track if fish tissue concentrations are decreasing, and monitor if the caps are effectively containing the contaminated sediment and/or groundwater. Data on contaminant levels in fish tissue will also help inform when and how the fish consumption advisory or other restrictions could be relaxed.

## 2.10.2 Evaluate Potential Changes Raised by New Data

### Comment Summary

A number of commenters stated that the feasibility study report and proposed plan fail to consider recent data collected between 2012 and 2014 in the evaluation of remedial action alternatives. Specific data sets that were referenced include the 2012 fish tissue sampling conducted by the Lower Willamette Group, the 2013 benthic health study by Germano & Associates, the 2014 sediment sampling conducted by Kleinfelder (Kleinfelder 2015) on behalf of a subset of Portland Harbor PRPs, and the 2014 sediment sampling conducted by GeoSyntec within Swan Island Lagoon. The commenters stated that these data demonstrate that natural recovery is occurring at the Site.

For example, it was noted that the sediment data collected by Kleinfelder indicate that the actual site-wide PCB SWAC is approximately 20 percent of the value used by EPA in the final feasibility study report and less than 50 percent of the value in the LWG 2012 draft feasibility study report and risk assessments. It was also noted that these new data generally confirmed EPA's PCB background level of the Site of 9 µg/kg but also indicated that a statistically significant reduction in the concentrations of PCBs in the river had occurred, consistent with the Lower Willamette Group's 2012 fish tissue results.

Similarly, it was noted that the data collected by GeoSyntec within Swan Island Lagoon show that PCB concentrations in the Swan Island SDU are mostly lower than what was used in the feasibility study report and that 75 percent of new samples showed reduced PCB sediment concentrations. One commenter stated that the public is not well served if EPA ignores this recently collected data.

The 2015 and 2016 NewFields reports stated that the PAHs in the vicinity of the former ExxonMobil Terminal are pyrogenic in nature and can be attributed to operations at the former Gasco property. The commenter believes that this new information should have been acknowledged in the feasibility study report.

One commenter stated that, collectively, the recent data demonstrate that the concentrations of contaminants in surface sediments have decreased significantly, and the concentrations of PCBs in fish tissue have declined since the original data collection. The commenter stated that these findings are not irrelevant when making decisions that are supposed to be based on science and should be considered in the selection of a remedy to reduce risk. Other commenters stated that EPA based its analysis on older data that no longer represent site conditions and disregarded more recent data, resulting in an alternatives analysis that is inappropriate and flawed.

Some commenters state that these data should be used to reassess key portions of the analysis, including revision of the RALs utilized to develop the remedial alternatives. The comment stated that when surface weighted average concentrations based on the newly collected data are used, EPA's knee of the curve analysis shifts away from Alternatives F and G toward Alternatives B and D. It was further noted that as the Site recovers before construction, the same RALs will delineate ever smaller areas of active construction. Failure to recognize these ongoing processes will cause errors in the selection of the most cost-effective remedy.

Some commenters also stated that the newly collected data demonstrate that the ROD should be sufficiently flexible to allow this additional information to be incorporated into the remedy and that EPA's remedy should describe what site-specific remedy adjustments will be allowed in the remedial design phase and how those adjustments would be determined and what procedural steps would be needed (such as explanation of significant differences or ROD amendment).

One commenter believes the composite subsurface sediment data are not representative and should not be used to estimate dredge volumes.

### **EPA Response**

As described in Section 1.3 of the feasibility study report (USEPA 2016b), the feasibility study data set included data collected under EPA oversight through authority of the Portland Harbor and Gasco and Arkema AOCs.

The feasibility study report used sediment data collected as recently as 2013, and presents and discusses contaminant concentration trends in fish using the data collected by LWG as recently as 2012. Thus, the assertion that data are a minimum of 9 years old is incorrect. As noted in the 2012 draft feasibility study report (LWG 2012), the large data set is considered adequate to represent current conditions and for evaluating alternatives in the feasibility study report (USEPA 2016b). Additional sampling to more fully assess “current conditions” is a remedial design issue and beyond the scope of the 2016 feasibility study report.

EPA evaluated and incorporated the smallmouth bass tissue data collected in 2012 in the 2016 feasibility study report. The results of this analysis are presented in Section 3.6.1.3 of that report. The evaluation focused on fish tissue data collected in 2007 and again in 2011/12; PCB tissue data for smallmouth bass collected in 2002 are not directly comparable with the data because individual fish collected in 2002 were composited by river mile without regard to side of the river prior to analysis. In 2007, fish were composited by river mile but segregated by side of the river prior to analysis, whereas fish collected in 2011/2012 were analyzed individually. The results of the analysis showed that in all but two instances (RMs 4E and 7E), concentration declines were not statistically distinguishable from zero. Possible explanations are the trend itself is close to zero, or the estimated coefficient could be very different from zero with a very wide confidence interval. The former would imply that the decay rate is small and that it is simply close to zero with strong level of confidence, whereas the latter indicates that the data are too sparse to precisely estimate the decay rate. As discussed in the response to LWG Dispute Issue 2c (Appendix A of this document), the sampling events are not sufficient to establish a reliable trend.

In general, a decision-making process cannot undergo constant modification when data are collected at various times and locations throughout the Site. There has been no new information that indicates that the nature and extent of contamination at the Site is significantly different than the remedial investigation/feasibility study data set indicates. Further, data presented in the 2015 Kleinfelder report do not on their face appear comparable to previously collected remedial investigation data (10cm surface samples vs the 30cm samples collected in the remedial investigation), making the conclusions therein regarding trends questionable. However, some conclusions provided in the August 7, 2015 memo to Jim Woolford and Cami Grandinetti are reasonable and consistent with the Agency’s position, specifically that natural recovery is occurring in the Willamette and is anticipated to continue and that the food web model is a useful line of evidence for representing sediment and food web contaminant relationships. However, EPA expects remedial footprints to be refined based on data collected during remedial design. For example, if sediment concentrations have declined through natural recovery, pre-design sampling should result in a smaller remedial footprint.

EPA acknowledges benthic recovery is taking place; however, benthic risk was not one of the main lines of evidence used to assess alternatives. While it may indicate that natural recovery is occurring, benthic risk was not used specifically in the evaluation of different alternatives. EPA concurs that natural recovery is occurring within Portland Harbor and that it should be utilized in the sediment remedies, as

evidenced by the fact that MNR represents the response action assigned to between 64 and 90 percent of the total area of the Site for all alternatives carried through the detailed analysis in the 2016 feasibility study report. However, the rate of natural recovery is expected to vary by location. It is important to have a representative data set that establishes “baseline conditions” prior to initiating the cleanup. Pre-design sampling will be used to ensure that the natural recovery is factored into the design and implementation of the sediment remedy and post construction monitoring will be used to evaluate natural recovery following remedy implementation. See also Sections 2.7.2 and 2.7.3 of this responsiveness summary.

Additional data will be collected during remedial design to assist in refining the remedy beyond the feasibility study level of analysis. EPA intends to evaluate additional data during remedial design to refine the delineation of contamination, selection and design of remedial technologies, and construction methods.

### 2.10.3 Explain Use of Non-Detects

#### Comment Summary

Comments received from Legacy Site Services state the proposed plan inappropriately uses elevated detection limits to calculate RALs and PTW footprints, which unnecessarily inflate the areas and volumes required for remediation and disposal to achieve risk goals. Legacy Site Services also stated that EPA should remove sample locations with PCB non-detect values with elevated reporting limits (e.g., > 1 milligram per kilogram) from the PCB footprint analysis as these bias and exaggerate the area of PCBs in sediment adjacent to the Arkema site. They further assert that RAL footprints should only consider detected PCBs based on PCB congener concentrations adjacent to the Arkema site, due to matrix interference with DDx in PCB Aroclor analyses. The commenter also requested that additional PCB congener data be collected from areas of non-detect sample locations with elevated reporting limits to confirm if PCB concentrations are present at these locations.

#### EPA Response

EPA used the data provided by LWG, including the commenter. LWG did not indicate that there were any issues with the data nor did they remove the data from the database provided to EPA. If there were issues with the data, LWG should have flagged the data and resampled using congener analysis. EPA agrees that congener, not Aroclor, data should be collected at this Site in remedial design. Review of the footprints shown in the feasibility study report (USEPA 2016b) for PCB RAL contours (Figure 3.4-7), DDx RAL contours (Figure 3.4-12), and dioxin/furan RAL contours (Figures 3.4-8, 3.4-9, and 3.4-10) indicates that the SMA footprint offshore of the Arkema property is largely driven by DDx and dioxins/furans and overlaps with the PCB RAL footprint; thus, omitting PCB data from this area would not substantially change the evaluation in the feasibility study report. New data will be collected in remedial design that will determine the SMA boundaries based on the final RALs selected in the ROD.

## 2.11 Modeling Issues

### 2.11.1 Explain Why the Mechanistic Food Web Model Is Appropriate

#### Comment Summary

Several commenters questioned the use of the mechanistic food web model to develop PRGs and highly toxic PTW thresholds. Three comments stated that, because the food web model was calibrated using data from both the near shore areas (where contaminant levels are higher) and the navigation channel (where contaminant levels are lower), it is inappropriate to use the food web model to develop PRGs

that are applied to nearshore SDUs. It was noted that the food web model assumes that all fish are exposed to the bank-to-bank, Site-wide average sediment concentration of a contaminant (i.e., the average across the near-shore areas and the navigation channel throughout the study area) but, as determined in a radio-tagging study performed in the Lower Willamette River, fish are more likely to feed in near-shore areas that contain higher contaminant sediment concentrations. Based on this information, the commenters concluded that the approach used by EPA overestimates COC bioaccumulation and subsequently results in sediment PRGs that are biased low and thus overly conservative sediment.

One commenter stated that, because of this bias, the bioaccumulation based PRGs should be applied on a Site-wide or full river mile basis. One commenter provided additional analysis showing that the SWACs estimated for RM 2 – 3 (full river mile) are lower than the SWACs estimated for SDU 2E for all alternatives and that the Alternative B SWAC for RM 2 – 3 of 32.5 µg/kg is slightly lower than the Alternative E SWAC for SDU 2E of 37.2 µg/kg.

It was also noted that there is a high degree of uncertainty associated with the development of tissue-sediment relationships and that because the food web model is used to derive sediment PRGs as well as to model fish tissue concentrations for estimating post-construction and residual risks, those uncertainties are carried throughout the remedial alternatives assessment. It was further noted that this degree of uncertainty is greater than the difference in post construction risk between alternatives.

One commenter provided a detailed critique of the food web model and concluded that the food web models have not been shown to accurately predict post remediation tissue concentrations and thus are not appropriate for setting sediment based remedial cleanup levels. The commenter also specifically noted that for Portland Harbor, the food web model was not run in a manner that would be able to predict post remediation concentrations, the model was not fully tested, and the calibration and validation approach provides no evidence the model can predict post remediation tissue concentrations.

The commenter also stated that fish collected at the Site have fish tissue concentrations consistent with non-urban stretches of larger Northwest rivers, and sediment remediation is unlikely to reduce fish tissue concentrations over much of the Site and will not result in the targeted tissue concentrations. The commenter recommended the identification of sources of PCB other than those released within the Portland Harbor, determine the relative contribution of all sources to the aqueous phase, model areas of the Site with different sediment concentrations separately, test the assumptions that the results are predictive at low sediment concentrations, use measured, not modeled pore water partitioning coefficients and acknowledge the uncertainty in the food web model.

Similarly, LSS commented that the conceptual site model does not adequately explain the relationship between surface water quality and tissue concentration and instead relies solely on sediment concentration which only explains about one third of the variation of DDX in fish tissue. As a result, they state sediment remediation will not achieve the desired tissue-related outcomes.

One commenter stated that the food web model was inappropriately applied to develop a PTW concentration threshold for total PCBs, and flaws within the food web model have resulted in calculation of a low-biased PTW concentration threshold. The commenter noted that the food web model is not sufficiently robust enough to develop sediment PRGs based on the fish consumption exposure pathway. As a result, the commenter undertook a more comprehensive review and re-evaluation of the food web model and included the results in a report. The commenter stated that because their model was calibrated more robustly, (1 million iterations vs. 9,982 iterations), it produced a calibrated model for

both Total PCBs and Total DDx that more accurately predicts measured average fish tissue concentrations and thus compels EPA to reconsider its use of the remedial investigation Mechanistic Model to derive the PCB PTW concentration threshold. The commenter noted that application of this model to define the PTW threshold would result in a highly-toxic PTW threshold of 500 µg/kg based on average fish tissue concentrations associated with a  $1 \times 10^{-3}$  cancer risk to subsistence fishers exclusively consuming fish caught in Portland Harbor (i.e., EPA's definition of the PTW sediment concentration threshold) rather than the 200 µg/kg presented in the feasibility study report and proposed plan.

### **EPA Response**

The food web model used to develop the PRGs was created by LWG to develop a predictive relationship between chemical concentrations in sediment, water, and tissue that can be used to derive PRGs for RAOs 2 and 6. EPA notes that the food web model was appropriately developed, parametrized, calibrated and applied to develop risk-based PRGs associated with RAOs 2 and 6 and, by extrapolation, PTW thresholds. EPA approved the model approach developed by LWG and determined the model could be used for decision-making at the Site. For more detail regarding the use of the food web model to develop PRGs, see Response to LWG Dispute Issue 11 (Appendix A of this document).

Regarding surface water concentrations, Section B1.3.3.1 of Appendix B of the feasibility study report (USEPA 2016b) describes the use of surface water concentrations in the food web model. Chemical concentrations in the water column were calculated using XAD water column samples collected during the seven sampling events at five transect locations and are presented in Tables B1-12a and B1-12b of Appendix B.

EPA acknowledges the uncertainty in the food web model but notes that many of the PRGs developed for preliminary sediment cleanup goals for contaminants found in fish tissue presenting unacceptable risk are based on background concentrations. The remedy will be evaluated through a robust monitoring program that will also include fish tissue monitoring. For example, PCBs are the COC with the greatest area of sediment contamination exceeding the PRG. Because risk-based PRGs resulting from the food web model are well below background, the sediment PRG for PCBs was developed based on an analysis of PCB sediment concentrations in the background data set, not on food web model relationships. Further, the remedial approach in the ROD is to address higher concentration areas and then allow MNR to achieve cleanup levels. RAL footprints represent the areas over which active remediation will be conducted and are a risk management tool used to target the most heavily contaminated sediments. Thus, areas of the sediment exceeding the RAL (not all areas that exceed the cleanup level) are targeted for remediation. In this regard, the uncertainty associated with the food web model does not markedly influence the alternative analysis or remedy selection because footprints are designated by RALs and PRGs were developed independent of the food web model. Overall, the combined uncertainty associated with each analysis and decision point is managed through a robust post-remediation monitoring program that ensures that fish tissue contaminant concentrations (and hence human health risk) are known post remediation so that identified risk, if any, can be managed through the five-year review process.

EPA disagrees with some of the statements. For example, one commenter noted that the food web model was not robustly calibrated. However, as described in the Bioaccumulation Modeling Report (Windward 2015), model calibration was performed through probabilistic analysis against contaminant data from multiple species collected throughout the Site (the calibration data set is described in Windward [2009],

Appendix F). Total PCBs was selected for initial calibration and run 50,000 times using Monte Carlo simulation (performed using Crystal Ball® software) with different combinations of plausible values for all calibrated, non-chemical-specific model input parameters and the best performing model run identified.

EPA also disagrees with statements that the food web model cannot be applied on smaller spatial scales. As described in the bioaccumulation modeling report, the food web model was applied on a study area-wide basis for calibration. However, the modeling effort also evaluated the model's ability to predict smallmouth bass and sculpin tissue concentrations on a smaller spatial scale for total PCBs. The same top performing model run was identified using the Site-wide and smaller-spatial-scale model runs thus demonstrating the models ability to perform on both the site-wide scale and smaller spatial scale. Based on this evaluation, it was concluded that model is predicting well on a smaller spatial scale for smallmouth bass and sculpin, which have home ranges that are less than site-wide. EPA hopes to further refine species home ranges, but what has been developed is sufficient to support the need to take action, and minimize reliance on MNR.

PCBs have been detected in smallmouth bass collected at the Site at concentrations that exceed the range of background levels presented in the comment, and multiple locations of PCB sediment contamination have been identified at the Site. EPA acknowledges that fish tissue samples collected outside Portland Harbor also contain PCBs. Similar to the Site, upstream areas with elevated PCB concentrations, such as RM 16, also have fish with elevated PCB concentrations. In addition, areas within the Site that have relatively low fish tissue PCB concentrations typically exhibit low sediment bed concentrations.

EPA disagrees that the risk goals established for the Site cannot be met. The analysis presented in the feasibility study report indicates that remediation of PCB-contaminated sediment is expected to reduce the concentration of PCBs in fish tissue. Additional efforts to eliminate sources of PCBs in the downtown reach and upriver are further expected to reduce PCB fish tissue levels. As is noted above, remedy performance will be evaluated through a robust monitoring program that will include fish tissue monitoring. The results of this monitoring effort will be used, in part, to determine whether additional sources of PCBs are present within the system that may limit the effectiveness of the remedy.

Regarding the model submitted in support of comments that support development of a 500 µg/kg PTW threshold, EPA notes that the food web model was appropriately developed, parametrized, calibrated and applied to develop risk-based PRGs associated with RAOs 2 and 6 and, by extrapolation, PTW thresholds. The commenter has not provided sufficient information to demonstrate that the proposed PTW threshold for PCBs of 500 µg/kg is more accurate than the current PTW threshold of 200 µg/kg. The use of 200 µg/kg as a PTW threshold was developed using a properly calibrated food web model and represents a  $1 \times 10^{-3}$  risk level for identifying PTW that is highly toxic, consistent with EPA guidance on identifying principal threat and low level threat wastes.

## 2.12 Conceptual Site Model

### 2.12.1 Conceptual Site Model Does Not Adequately Characterize the Site

#### Comment Summary

Comments regarding the CSM were submitted by several parties, including the PCI Group, USACE, EVRAZ Inc., LSS, LWG, RM 11E Group, Exxon Mobil, and Union Pacific Railroad. Several of the commenters (the PCI Group, EVRAZ Inc., LSS, LWG, RM 11E Group, ExxonMobil, and UP Union Pacific Railroad) indicated that the CSM presented in the feasibility study report (USEPA 2016b) (Figure 1.2-

26) does not adequately characterize actual site conditions and the complexity of the Site and identified one or more elements of the CSM that should be added or improved, including:

- Effects of background conditions; the importance of non-steady state conditions
- Critical role of spatial complexity associated with sedimentary parameters such as grain size and organic carbon
- Site uses
- Biological habitats
- Potential habitat restoration sites
- Biological receptors in sediment and surface water
- Biogeochemical recovery pathways; how humans access and use the river for navigation and recreation
- Chemical distributions in subsurface sediments
- Contaminant sources including upstream chemical inputs to surface water
- Extent of highly mobile sediment
- Recent analytical data

Commenters (PCI Group, LSS, ExxonMobil, EVRAZ Inc., and Union Pacific Railroad) said that a predictive quantitative model (e.g., hydrodynamic and sediment transport model) is needed to make cleanup decisions and select alternatives. Exxon Mobil also stated that a site-specific fate and transport model is needed for evaluating remedy effectiveness and the benefits of remedial methods. Comments also stated that EPA's CSM was not developed in accordance with EPA and other applicable guidance. Because of these deficiencies, commenters stated that the CSM cannot be used to support the development and evaluation of the alternatives identified in the proposed plan. USACE also stated that the CSM should be modified regarding assumed exposure scenarios associated with aquatic disposal of dredged material. LSS commented that because the CSM fails to address background water quality and contaminant sources (e.g., mercury in fish tissue), there will still be fish advisories for contaminants not related to Site COCs.

### **EPA Response**

EPA disagrees with the assertion that the CSM is inadequate and cannot be used to support alternatives evaluations. The CSM, as documented in Section 10 of the remedial investigation report (USEPA 2016a) was developed in accordance with EPA guidance, *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA* (1988) and *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (2005). The CSM presented in Figure 10.1-1 of the remedial investigation report (USEPA 2016a) and Figure 1.2-26 of the feasibility study report (USEPA 2016b), provides a visual summary of the environmental system, contaminant sources, affected media, fate and transport processes, and human and environmental receptors. The remedial investigation report further describes each of these elements in detail. The CSM and the information presented in the remedial investigation report re based on a robust data set collected by LWG under EPA oversight.

Commenters contend that the CSM incorrectly assumes that surface sediment and surface water concentrations across the Site exist at steady state. The CSM in the remedial investigation report describes the lower Willamette River as a dynamic river system (see Portland Harbor remedial investigation report (USEPA 2016a), Sections 3 and 10) (USEPA 2016a). EPA's assumption was that the Site is in dynamic equilibrium, not steady state. See LSS Dispute Issue 1 (Appendix A of this document).

Several commenters contend that the CSM needs to be represented by a predictive quantitative model that incorporates site conditions, contaminant distribution, and multiple fate and transport processes. Quantitative models have been developed for the Portland Harbor Site but they have not been found to effectively represent the CSM. As described in Section 4.1.2 of the 2016 feasibility study report, a hydrodynamic and sediment transport model was developed by LWG and presented in the draft feasibility study report (LWG 2012). EPA commissioned external expert reviews of this model, which identified several shortcomings that limit its usefulness in predicting sediment transport within the Site (see Appendix H of the 2016 feasibility study report). EPA reviewed the predictability of the 2012 draft feasibility study report QEA Fate Model and found its predictability poor. EPA also did not use the SEDCAM sediment recontamination model as it only predicts deposition, not erosion, and is thus inconsistent with the CSM. EPA concluded that existing empirical data and information about the Site and contamination was sufficient for remedy decision-making given the lack of sufficient data to adequately populate a model that could simulate conditions on such a complex system. See EPA's position response to LWG requested relief 2 and LWG Dispute Issues 2a and 2b (Appendix A of this document).

Even LWG acknowledged the lack of data necessary to develop such a model, and that any model developed would have great uncertainty in predicting the outcomes of any alternative developed for the Site. See EPA's position in response to LWG Dispute Issue 2a) (Appendix A of this document). EPA believes that the CSM along with all of the information contained in the remedial investigation report and information used in the 2016 feasibility study report (USEPA 2016b) are sufficient under CERCLA, the NCP and EPA guidance to develop and select a remedial alternative.

The activity-specific human health and ecological risk assessment CSMs suggested by USACE can be beneficial but, as suggested by USACE, EPA does see the value in developing activity-specific human health and ecological risk assessment CSMs and will consider use of this approach during remedial design. Following the collection of additional data during remedial design, exposure scenario assumptions will be reevaluated as needed. For additional information regarding EPA's position on this issue, please see EPA's response to Union Pacific Railroad's Dispute Issue 5, LSS's Dispute Issues 1, 5, and 20, and LWG's Dispute Issues 2a and 2b (Appendix A of this document).

### 2.12.2 The CSM Does Not Properly Consider MNR

#### Comment Summary

EPA received several comments regarding the evaluation of MNR at the Portland Harbor Site. Comments included statements that the Site was lacking a CSM that properly considered MNR; some of the data used in the feasibility study evaluations was outdated and more recent data including fish tissue and sediment sampling results were not properly incorporated into the MNR evaluation; the use of interim cleanup targets was inappropriate; and a quantitative evaluation of MNR was not conducted as part of a multiple lines of evidence evaluation.

One commenter stated that multiple lines of evidence, including time series bathymetry data, the fine-grained nature of the majority of Site surface sediments, surface to subsurface sediment contaminant

concentration ratios, and detailed sediment transport modeling, all indicate that the majority of the Site surface is a depositional system. The commenter stated that empirical bathymetric data indicate 63 percent of the Site is depositional and an additional 25 percent of the Site is stable (no substantial bed elevation change). Thus, approximately 88 percent of the Site is stable or depositional. This is an important element that should be explicitly operationalized because natural recovery represents one of the important core processes in the site CSM.

Another commenter disagreed with statements by EPA that “sediment trend data do not exist for this Site; insufficient biota and water trend data exist” and “the hydrodynamic and sediment transport model predictions are inconsistent with the CSM for this Site.” The commenter stated that a significant amount of information collected during the remedial investigation demonstrates that river conditions have changed over time. For example, EPA’s RJ found that, “Concentrations of total PCBs, DDX, total PAHs, hexachlorobenzene, total chlordanes, aldrin and dieldrin, gamma-HCH, lead, and TBT are higher in subsurface than in surface sediments, indicating that historical inputs were likely greater than current inputs.”

### **EPA Response**

EPA disagrees with the commenters that MNR was not considered in the CSM for the Site. The final remedial investigation report (USEPA 2016a) included a comprehensive CSM that considered sediment dynamics (Section 10.1.1), including evaluation of sediment trap data and sediment deposition rates developed based on bathymetric change data. In addition, the feasibility study included a multiple lines of evidence evaluation of MNR. Section 3.6.1 of the feasibility study report (USEPA 2016b) presents a summary of the lines of evidence considered during the evaluation of MNR. These include incoming sediment particle concentrations, sediment deposition rate, and fish tissue concentration trends. Other factors that were considered are described in Appendix C of the feasibility study report and include the ratio of subsurface to surface sediment concentrations, wind and vessel wake-generated waves, predicted bottom shear in comparison to critical shear stress and propeller wash. These multiple lines of evidence indicate that the majority of the Site surface is amendable to MNR. See Section 2.16 of this responsiveness summary for additional information related to hydrodynamic sediment transport modeling and other MNR issues.

## **2.13 Cleanup Technologies – Capping and Dredging**

### **2.13.1 Capping Is Not an Appropriate Technology**

#### **Comment Summary**

Eleven personal comments expressed concerns with capping, either as a cleanup technology altogether or related to how the caps would be designed (e.g., use of concrete on river banks). One comment noted that EPA itself believed it was inappropriate at megasites, and several people said that capping was only temporary and that contamination would eventually be released.

Representative comments include:

- “Alternative I can best be described as a system engineered to release our harbor’s non-degradable contaminants into the environment at a rate that stays within pollution-control standards. For example, it calls for “capping” more severely contaminated areas of the harbor floor with clay. We can expect harmful contaminants to continue leeching from these areas, but more slowly. Caps are, in effect, time-release mechanisms, delivering a lower dose of contaminants to our environment over a longer period of time. The long-term effect is that all the

non-degradable contaminants will ultimately diffuse into the environment, and into the food web.”

- “Capping is not restoring natural habitat. Portland needs and deserves a clean river, not a concrete ditch. The river must be clean and safe for fish, birds, and other wildlife. Restore a natural river bank, not a lot of concrete and capping.”
- “In EPA’s recommendations and advocacy for capping, they state that it is inappropriate at “industrial megasites” [iii] With ten miles of industrial waste, the Portland Harbor certainly meets the definition. Why New Technologies. Collecting, learning from, and incorporating new information into practice is the only avenue to improving the effectiveness of remedial operations. Regardless of cost or controversy, achieving the expected effect of remedial actions—improvements in the environment—is of primary importance.”
- “I am not very comfortable with the capping plans, I don’t feel like the river bottom is a secure place, that can be just kind of once you cover something there that it’s gone, I feel like that’s not really cleaning up the mess. I’m less concerned about who’s a responsible party than I am about getting the poison out of the river so that it doesn’t affect animals and people and, you know, future generations all the way down to the ocean.”
- “Capping is just leave contaminants in place to be released by disturbance later. Ships aren’t getting smaller - someone will want to dredge a deeper channel into the harbor eventually. The only way to prevent recontamination by capped sediments is to physically remove all contamination now, to a secure off site location (one where it will not recontaminate its new location).”

### **EPA Response**

EPA recognizes containment as an effective way to isolate or immobilize contaminated sediment through capping technologies under the right conditions and in specific locations. The mechanics, effectiveness and implementability of various capping technologies are discussed further in Section 2.3.5 and Table 2.4-2 of the feasibility study report (USEPA 2016b).

None of the caps being recommended at the Portland Harbor Site utilize concrete in their design. The suggested cap designs include both passive and active (reactive) caps designed to physically isolate and sequester contaminants for extremely long design periods. Reactive caps such as those containing activated carbon do not just provide a physical isolation layer between the contaminated sediments and the water column, but also actively bind the contaminants to their surfaces, lowering their availability to organisms the cleanup seeks to protect. That is why these are termed active caps and this binding to the reactive amendment is usually irreversible under normal environmental conditions. Cap designs will account for more frequent flooding likely with climate change, as well as other considerations such as vessel wakes and prop scour.

All caps require long-term maintenance, thus issues such as disturbance due to navigation would be monitored and remedied as necessary, the details of which would be included in a long-term monitoring plan. Consistent with Clean Water Act § 404(b)(1) guidelines, where the remedial action adversely impacts habitat, the cap will be designed to minimize the impacts and restore the surface for habitat function, and if loss of habitat occurs, compensatory mitigation will be undertaken. The details of any necessary mitigation to protect habitat would be developed during remedial design. For example, the feasibility study assumed equivalent cap thickness is dredged prior to placement to allow for a net zero

bathymetry change thereby limiting the need for mitigation. The ROD provides a remedial technology decision tree and design considerations for proper planning and applicable conditions under which capping technologies can be considered for the remedy.

### 2.13.2 Dredging Should Be Minimized

#### Comment Summary

Comments were received from Calbag Metals Co. and LWG that cited evidence suggesting that fish tissue PCB concentrations will temporarily increase for a period of years during and following dredging. Their concern was that this was not evaluated in the comparison of alternatives. LWG also criticized the use of zero as a replacement value for dredge areas after construction was completed.

Calbag Metals Co., the City of Portland, LWG, and Siltronic Corporation all commented on the need for evaluation of short-term impacts of dredging during and right after construction. The impacts cited included negative effects on shipping schedules within the harbor, ships leaving the harbor, potential damage to the ecological community at the bottom of the river, increased diesel emissions due to transportation of sediment to and from the Site, noise impacts to the local communities, and potential increase in contaminant concentrations in fish tissue for short periods of time. LWG also believed that no new quantitative evaluations for dredge release and residuals have been conducted, and both LWG and Siltronic commented on the use of only one study (Hudson River) on dredge releases and the limited selection of dredging BMPs.

According to The Marine Group BAE, EPA's assessment of river bank excavation was also deemed overly general and technically impractical, and the use of in-place technologies was suggested instead.

#### EPA Response

EPA's 2005 Sediment Remediation Guidance, Section 6.5.5 "*Predicting and Minimizing Sediment Resuspension and Contaminant Release and Transport During Dredging*" (USEPA 2005) states:

- "Some contaminant release and transport during dredging is inevitable and should be factored into the alternatives evaluation and planned for in the remedy design. Releases can be minimized by choice of dredging equipment, dredging less area, and/or using certain operational procedures (e.g., slowing the dredge clamshell descent just before impact with the sediment bed)."

The feasibility study report (USEPA 2016b) explicitly states that some contaminant release is inevitable in the alternative assembly and evaluation (Sections 3.4.8.5, 3.4.8.6, and 3.4.8.10). The discussion describes results from other recent and relevant dredge operations and focuses on technological and operational procedures for lessening release and resuspension as discussed further below.

Post-construction COC concentrations in areas assigned dredging or capping were assumed to be zero immediately after operations, as the 2016 feasibility study report assumed clean material would be used for caps, and that the residual layer applied to dredged areas for the purpose of addressing contaminated dredge residuals would consist of clean sand. Thus, potential increased effects on fish tissue concentrations were also assumed to diminish right after construction. The feasibility study report assumptions are supported by observations at the Grasse River Remedial Options Pilot study and the Hudson River Phase I dredging where fish tissue concentrations that spiked during operations (presumably related to contaminant releases) were generally not elevated above baseline after dredging ceased (the increased concentrations did not persist for "years" following construction). Importantly, it was also these projects that led to many of the lessons learned regarding engineering and operational

controls of sediment resuspension and contaminant release and the management of dredging residuals. EPA's response to LSS Dispute 8 (Appendix A of this document) also contains relevant information on this issue.

The feasibility study report release estimate emphasizes results from Phase 2 of the Hudson River dredging because it was a recent (2011-2015), large, multi-year dredge project, with site and operational characteristics similar to the dredging proposed in the feasibility study report (contaminated sediment removal in a large, riverine environment with multiple mechanical dredges using barge transport). Hudson River Phase 2 dredging operations incorporated lessons learned from Phase 1 dredging and recommendations from the Hudson River Peer Review Panel. Thus, the project represents state-of-the-art approaches for managing dredge releases while maintaining (or increasing) productivity. The peer review report states, "The repeated dredge passes and prolonged exposure of sediments in the certification units resulted in increased PCB resuspension and release." To minimize resuspension and release, the panel recommended to improve depth of contamination estimating procedures and to:

- "Establish BMPs to limit sediment resuspension and release.
- Perform confirmation sampling in each 1-acre sub- certification unit as soon as possible after attainment of the DoC Elevation in 95 percent or more of the area is confirmed by EPA.
- Place a 3 to 6-inch sand cover over sub- certification unit as soon as possible after confirmation samples are collected (before PCB analytical results are obtained).
- Use PCB analytical results of composited surface samples to determine whether an area will be backfilled or capped and install final layers accordingly."

Due to the Peer Review Report's recommendations, the feasibility study report also emphasizes BMPs to limit sediment resuspension and release and placement of residual sand cover of 12 inches to lessen short-term impacts and enhance the effectiveness of dredging and capping to achieve the final cleanup goals within a reasonable timeframe. EPA's final selected remedy incorporates these BMPs as requirements.

Regarding assessment of short-term impacts, EPA guidance states that short-term impacts should be identified and the trade-offs between alternatives discussed, and that is what EPA did in its feasibility study. The nature of the impacts is the same for all alternatives; the differences are magnitude and length of time with the increased construction with each alternative. Section 4.3.5 of the 2016 feasibility study report discusses the trade-offs for short-term effectiveness between alternatives. EPA states that the impacts for any alternative will be for 4 months per year and last the duration of the construction project. The Clean Water Act Section 404(B)(1) Evaluation found in Appendix L of the feasibility study report and the Programmatic Biological Assessment also discuss several other short-term impacts in detail. Additionally, the short-term impacts identified by the City of Portland have been discussed in Sections 2.17.4 and 2.20.1 of this responsiveness summary.

Furthermore, engineered rigid control measures were one of the BMPs considered to address dredge releases. Engineered rigid control measures were evaluated holistically in the 2016 feasibility study report for their use in reducing or eliminating short-term releases of contaminants during construction and not on a location-specific basis. Thus, the 2016 feasibility study report does not present figures indicating design level logistical details regarding location and depth of engineered rigid control measures. Sheet piles are a representative engineered rigid control measure identified and evaluated for

sediment dispersion control. However, that representative approach does not preclude other types of BMPs for consideration during remedial design. Details regarding sediment dispersion control and location-specific engineered rigid control measures will be determined during remedial design, which is the appropriate time for those types of evaluations.

The navigation channel and future maintenance dredge (FMD) areas were assigned dredging technology within SMAs. This approach is consistent with the LWG 2012 feasibility study report. Dredging is an essential part of achieving an effective remedy for the contaminated sediments at Portland Harbor. While the proposed plan (USEPA 2016c) indicates that exact depth of contamination is unknown at this stage, it also specifies that actual dredge depths will be established based on data collected during remedial design. If contamination in the navigation channel or FMD areas is too deep to be dredged, an isolation cap residing below the depth of navigation channel maintenance will be considered as appropriate. Detailed dredging volumes will be evaluated during the remedial design, and arbitrary depths will not be assigned as suggested by some commenters.

Currently, the contamination in the river banks is uncontrolled and either is migrating or has the potential to migrate to the river. There are tidal fluctuations twice daily, submerging portions of the river bank throughout the day, potentially exposing aquatic receptors to the river bank contamination. Furthermore, the river water levels rise and fall seasonally; thus, again submerging different portions of the river bank throughout the year. Other forces, sheet flow, gravity, or upland land uses, can lead to river bank soils eroding into the river. Therefore, river banks are appropriate to include in the cleanup plan. More details about existing conditions, contaminant concentrations, and design-level information will be obtained that will determine whether excavation of any particular river bank is required and, if so, how much and how the river bank will be restored, depending on reasonably anticipated future use, Endangered Species Act/404 requirements and long-term effectiveness considerations. See also EPA's response to LWG Dispute Issue 1q (Appendix A of this document).

EPA did evaluate all available technologies to specific areas in development of the alternatives and selected the appropriate technology to use based on site-specific environmental and anthropogenic conditions. However, the ROD decision tree demonstrates that there is flexibility in the technology assignments based on criteria to be evaluated during remedial design.

### 2.13.3 Use of Sheet Piles for Containment Was Not Properly Evaluated

#### Comment Summary

Thirteen comments were received expressing concerns with the use of sheet piles for containment during dredging of contaminated sediments. They are:

- It is inappropriate to use rigid containment for dredging sediment adjacent to Arkema. The proposed plan identifies that sheet piles are needed to address the large NAPL plume (incorrect assertion on plume size) offshore of the Arkema Site.
- There is no quantitative evidence of estimated dredge residuals or releases associated with dredging. EPA guidance recommends comprehensive evaluation of dredge impacts.
- Technical challenges exist due to site characteristics. Sheet piles will not contain the release of contaminants to surface water.

- EPA should explain when conditions may warrant changes to major alternative elements and when EPA may consider or allow the site-specific engineering evaluations.
- Site-specific evaluations determined that the use of sheet pile walls for containment during dredging would only be partially effective for containing releases. Sheet pile walls would impound contaminated water, which would be released when the walls were removed.
- Sheet pile walls are not water tight.
- Sheet pile containment would add significant cost, increase implementation risks, and increase construction duration.
- Sheet piles would mobilize NAPL to greater depths and to the sediment surface through smearing.
- Using sheet pile wall containment would pose a significant risk to worker health and safety.
- Scour around the perimeter of the sheet pile wall could cause structural failure and mobilize contaminated sediments.
- Sheet pile walls may not be sufficient, and a more expensive cofferdam-type system may be needed/evaluated.
- USACE will not allow sheet pile walls in the navigation channel.

### **EPA Response**

The use of sheet piles was adequately evaluated relative to other control technologies and best management practices in the feasibility study report (USEPA 2016b). Sheet piles are a representative engineered rigid control measure identified and evaluated for sediment dispersion control in the 2016 feasibility study report. However, that representative approach does not preclude other types of rigid control measures for consideration during remedial design. Engineered rigid control measures were evaluated holistically within the 2016 feasibility study report for their use in reducing or eliminating short-term releases of contaminants during construction and not on a location-specific basis. Thus, the feasibility study report does not present figures indicating design level logistical details regarding location and depth of engineered rigid control measures. Location-specific evaluations for feasibility of sheet pile versus other types of engineered rigid control measures, including placement within the navigation channel, were beyond the scope of evaluation of the feasibility study report and will need to be evaluated during the remedial design. Details regarding sediment dispersion control, mitigating NAPL smearing, and location-specific engineered rigid control measures will be determined during remedial design, which is the appropriate time for those types of evaluations. Additionally, the remedial design will need to account for over-water structures, buried structures or debris, and geotechnical properties of the sediment bed.

The determination of technical feasibility of engineered rigid control measures is highly dependent on site-specific conditions. As stated in Appendix O of the 2016 feasibility study report, EPA agrees that depth can limit the use of suitable engineered options for controlling releases, and deep water depths can preclude the use of sheet piles. However, blanket elimination of the technology is not warranted given its effectiveness in reducing migration and dispersion of contaminated dredged material.

Remedial activities with the potential to restrict navigation in the harbor channel will be coordinated with the USACE and the Coast Guard during remedial design, including efforts to minimize sediment

dispersion in areas where NAPL extends into the navigation channel. The Rivers and Harbors Act prohibits obstructions to navigation, but CERCLA requires remedies to be protective of human health and the environment, and other federal statutes require measures to reduce impacts to Endangered Species Act species or the aquatic environment as well. No permanent obstructions will result from the cleanup, but some disruption to navigation may be needed to implement the remedy that will protect human health and the environment.

Risks to worker safety during construction will be addressed by the site-specific safety plan (Accident Prevention Plan). Responses related to the cost of sheet pile wall construction are included in Section 2.22 of this responsiveness summary.

## 2.14 Cleanup Technologies - Disposal

### 2.14.1 Do Not Use a Confined Disposal Facility

#### Comment Summary

A total of 1746 comments were received that expressed unhappiness with a CDF at Terminal 4. The vast majority (1313) were part of a form email or postcards, and included these statements:

- “EPA should eliminate the confined disposal facility which would create a permanent toxic waste dump in our river.”
- “Toxic dredged sediments must be taken to an appropriate landfill. Creating a toxic waste disposal dump in our river is not acceptable.”
- “Creating a toxic waste disposal dump in our river is not acceptable—toxic dredged sediments must be taken to an appropriate landfill.”
- “Select disposal options that do not include a Confined Disposal Facility and that do include treatment of dredged sediment to breakdown or bind contaminants.”

There were also hundreds of personal, individual comments which were all against the CDF. Representative examples of these comments include:

- “Thank you for your service to the community. Please pursue a cleanup alternative that adequately restores the endangered health of our river. Dredging must be removed from the vicinity and not stored in terminal 4.”
- “Please listen to the task force that has watched this for a decade or more, and is in the best position to give technical advice on how many acres, what should be cleaned, where it should be dumped, and for Heaven sakes do not dump it back in the river someplace else. What a crazy idea.”
- “Thank you for leading an effort to cleaning our river. Do not place dredging in the terminal 4 locations please. Terminal 4 provides sturgeon habitat and tremendous sustainable economic activity at the port.”
- “The river should be dredged of the toxic waste to remove it from the Willamette and be taken to an appropriate landfill where it will not affect the livability of that area.”

- “Take toxic dredged sediments to an appropriate landfill. Confined disposal facilities and capping of dredged sediment are problematic. EPA should remove contaminants from the river, not simply stored in or next to the river. It takes hundreds to thousands of years for substances to degrade. During that time, toxics can build up in the ecosystem and eventually be released into the Columbia River and ocean. Conditions of climate change, tectonic activity, and flooding increase likelihood of exposure.”

Finally, the Port of Portland submitted comment withdrawing their support for the use of Terminal 4, including:

- “EPA has identified two disposal scenarios, one using only off-site landfills and another selecting a CDF at Terminal 4 for a portion of sediment disposal. The Port encourages EPA to retain optionality in the ROD to incorporate other disposal mechanisms not specifically presented for evaluation at the time of the feasibility study and proposed plan. This is critical because the Port has concluded that a Terminal 4 CDF is no longer the right decision for the Port. The Port continues to agree with EPA that the Terminal 4 CDF would be safe for people and the environment. However, given uncertainties in factors like cost, design, acceptance criteria, and performance criteria, the financial viability of the Terminal 4 CDF relative to other options appears marginal and could deteriorate if less expensive landfill or other disposal options materialize. Moreover, a CDF would be a significant, permanent commitment at Terminal 4, imposing long-term responsibilities on the Port and straining the Port’s relationship with neighboring communities who have consistently opposed the CDF. For all these reasons, the Port has concluded that the CDF is not an appropriate use of limited Port resources.”

### **EPA Response**

The feasibility study report (USEPA 2016b) analyzed and the proposed plan (USEPA 2016c) described the two disposal options for dredged sediment resulting from the cleanup. The proposed plan indicated that the preferred disposal option was using a CDF and off-site disposal facilities for dredged sediment that was not suitable for a CDF. A CDF would reduce the number of bargeloads, trainloads, and/or truckloads of sediment requiring off-site disposal, reducing impacts to surrounding communities. Reducing the transport distance for disposal would also reduce the chance that accidents and/or spillage of contaminated sediment could occur. However, the primary benefit of off-site disposal of dredged material is that it avoids the long-term maintenance requirements of a CDF and impacts on the aquatic environment by filling approximately 14 acres. It also removes the waste completely out of the system, providing assurance that no recontamination will occur as a result of an unanticipated event impacting the integrity of the CDF structure. Further, off-site disposal transfers management of the waste to professionally-permitted waste handlers whose primary focus is the safe and effective handling of hazardous waste materials.

The Port of Portland, who was originally providing the land for the facility (at Terminal 4), indicated in its official comment submission that it has withdrawn its sponsorship of the CDF which impacts the implementability of the CDF. Because of this new circumstance, the small difference in cost savings using a CDF relative to overall project cost estimates, and the overwhelming sentiment expressed by the public against the CDF, EPA has decided to select off-site disposal for all dredged sediment as part of its final remedy.

### 2.14.2 Develop a Commercially-Viable Sediment and Soil Disposal Facility

#### Comment Summary

The City of St. Helens provided information about a proposal for developing an existing waterfront property (wastewater treatment lagoon) into a Resource Conservation and Recovery Act Subtitle D facility with barge transfer infrastructure that could be used to disposal of dredged contaminated sediments from the Portland Harbor Site.

#### EPA Response

EPA recognizes that potential significant cost savings could be realized if a geographically proximate disposal facility is available for disposal of dredged contaminated sediments and excavated river bank soils. In addition, a nearby facility could reduce air emissions of greenhouse gases and air toxics from diesel emissions. Such a facility would not be part of the CERCLA response but rather would be a permitted facility under the Resource Conservation and Recovery Act/State Hazardous Waste or Toxic Substances Control Act. If such a facility was permitted and was found acceptable under the Off-Site Rule, EPA would consider disposing of waste in that facility.

### 2.14.3 Revisit the Waste Disposal Designation for Sediment Adjacent to Arkema

#### Comment Summary

A comment was received stating that EPA has arbitrarily made more conservative assumptions for disposal of PTW defined by sediments containing DDx and NAPL than it has for PCBs, dioxin/furans, and PAHs. Based on current data, none of the sediment offshore of the Arkema site should be classified or handled as a federal- or state-listed hazardous waste, or as PTW requiring treatment.

#### EPA Response

Please see LSS Dispute Issue 3 (Appendix A of this document).

### 2.14.4 Explain the Cost Assumption for Treatment of PTW Near Arkema

#### Comment Summary

A comment was received disagreeing with the cost assumption that "cement solidification/stabilization, low temperature thermal desorption, and no treatment will be used in equal proportions to treat pesticide/chlorobenzene PTW" for the disposal of dredged sediment that meets EPA's PTW criteria offshore of the Arkema site.

#### EPA Response

Please see LSS Dispute Issue 3 (Appendix A of this document) for a response to this comment.

### 2.14.5 Use the Hazardous Waste Identification Rule Appropriately

#### Comment Summary

EPA disregards the scope and intent of the Hazardous Waste Identification Rule by placing arbitrary restrictions on what EPA believes can be placed into a CDF, if constructed. All of EPA's acceptance criteria for a CDF are arbitrary and must be removed. Disposal of dredged material must follow the Hazardous Waste Identification Rule as adopted by the state or follow the Resource Conservation and Recovery Act if disposed of at an upland landfill. EPA has correctly stated that Resource Conservation Recovery Act regulatory requirements (including the designation of waste sediment as either a federal- or state-only hazardous waste) do not apply to sediment placed in a CDF, it mischaracterizes the Clean Water Act requirement that the sediment must meet CDF acceptance criteria for this rule to apply.

**EPA Response**

Since EPA's selected remedy is not using an on-site CDF, the issue of what waste could go into a CDF is moot.

**2.14.6 Be Aware of Additional Waste Management Needs****Comment Summary**

The waste disposal narrative in the feasibility study report indicates that if Gasco MGP waste is found to be commingled with spent halogenated solvents from the Siltronic site, "the material will be classified as a Resource Conservation and Recovery Act listed hazardous waste for management and disposal purposes."

**EPA Response**

EPA notes that the discussion of material disposal in the Consent Order's statement of work is in the context of an early action sediment cleanup performed under an engineering evaluation/cost analysis prior to the harbor-wide ROD. The GASCO cleanup must comply with the ROD including disposal of MGP waste. MGP waste will be disposed of in a Subtitle C disposal facility, consistent with the December 2004 dispute. This categorization is based on regulatory, material handling (off-site tracking), and health and safety considerations that will be refined during design. EPA has taken into consideration the material disposal discussion presented in the Consent Order statement of work during development of the ROD for the Site. As noted in the feasibility study report (USEPA 2016b), F002-listed wastes that originated from Siltronic will be treated as such per applicable Resource Conservation and Recovery Act regulation.

**2.14.7 The ROD Should Allow for Ex-Situ Characterization of Waste****Comment Summary**

One comment was received stating that the ROD should allow for ex-situ characterization of waste as has occurred at other sediment sites. Other sites have demonstrated that ex-situ sampling of dredged material typically results in the removed and dewatered sediments being cleaner than anticipated based on in-situ characterization and oftentimes allows for nonhazardous disposal in a Subtitle D landfill.

**EPA Response**

In-situ sampling of sediments has been conducted to characterize the nature and extent of contamination in the river, as well as to identify potential sources of contamination. The feasibility study report (USEPA 2016b) is based on the environmental data collected and compiled by LWG and other parties since the inception of the Portland Harbor remedial investigation and feasibility study in 2001. Additional and more extensive site data will be collected during the design phase.

For disposal purposes, analytical testing results of dredged sediment will be used for waste classification and subsequent determinations of disposal facility acceptance, including any required pre-treatment or treatment of wastes. Data collected during remedial design will initially be used for this purpose. The actual amount of removed material subject to ex-situ treatment would depend on the analytical tests used to classify wastes in accordance with the ROD.

It should be noted that assumptions made for categories of waste, including PTW, and subsequent quantities for treatment and disposal were suitable and reasonably supported by existing data for purposes of evaluating and comparing cost and other balancing criteria for alternatives in the feasibility study report. The actual volumes for waste treatment and disposal will be determined during the remedial action.

## 2.14.8 Clarify Uncertainties for Assumptions on Ex-Situ Treatment and Transloading

### Comment Summary

One comment was received from the City of Portland requesting clarification on EPA's assumptions about the location of a transloading facility and asks for flexibility to more fully evaluate the feasibility of a transloading and treatment facility within the Site. Ultimately, if a transloading facility is going to be located in the Harbor, the city requests that EPA work with the City to find an optimal location with the least amount of negative impact on the community.

### EPA Response

Please see the Cost (Section 2.22) and Implementability (Section 2.21) responses in this responsiveness summary.

## 2.15 Innovative and Sustainable Technologies

### 2.15.1 Evaluate Emerging Technologies throughout the Process

#### Comment Summary

A total of 41 comments were received on this topic. About half were included in form emails and stated

- “Accept the new technology options that will reduce costs and improve long-term effectiveness. These may be conducted as pilot projects.”

The remainder echoed this sentiment and some provided specific suggestions. Representative comments from that group are:

- “The feasibility study has not adequately included newer technologies, including dredging technologies that have been successful at other sites and could be much less invasive on the river and the river banks.”
- “The potential for cost savings through the application of new technologies seems to be understated in the proposed Plan I. Future sites in other locations will benefit from knowledge gained from trying them on this site. We can benefit from the learning curve. Bacteria, sediment washing, and oven cooking to breakdown PCB's all have potential to minimize transportation expenses.”
- “Look to newest techniques of dredging - Better than EPA's proposed dredging technique - Think outside the current box!”
- “I don't think what they're proposing, removal, containment, natural recovery, it's the old industrial model, and it's not very inspiring and even what they're proposing to do of these three components is simply not enough. I'm really disappointed that there's no bio remediation happening that I can discern.”
- “I would like to see the most contaminated areas dredged and the poisonous material dealt with until it's no longer poisonous, not just moved to another site, especially if that site is still in a flood land area like is proposed. You know, maybe it can be used to make concrete for an airport strip or something far away or I like the idea of burning the chemicals out of it in a safe way.”

- “Thank you for all that you are doing! Curious if conservation Districts are partnered in some way? I recently went to a wonderful workshop on mycolium /medicina mushrooms mycology and its potential for clean up even in salt water. I wonder if Ozone was pumped into rivers it would add to the healthiness of the water. Large scale sump pump filtrations and certain algae may be worth investigating also curious about dredging deep and composting the silt? P.S. I have a 7 stage reverse osmosis (kitchen version) and every 3 months I have to trade out the prefilters, and carbon filter, and Zeolite. I can see by observation how bad the NE Portland tap water is.”
- “There are many emerging technologies available for river cleanup, yet it appears that EPA has not considered their use. Dredging techniques that clean more sediment more efficiently should be used.”
- “Micro-Bac International’s M-1000H microbial solution and Tri-Phasic12 nutrient solution has been successfully used to treat organic contamination in a harbor bottom in Italy. The bottom line is that the site could be treated in place for substantially less money than what has been proposed. If you still chose to dredge, it could be treated in your containment area with no need to cap.”
- “Use new and emerging technologies, such as those developed by NASA, bio-remediation bacteria that works on PCBs and DDT's and dewatering on barges.”
- “We want to use Nasa Dev redeployable Polmer blanket technology for inset removal of PCBs in approach to remove & treat PCBs sediments in place, eliminating the need for dredging (\$) or capping. We want "NEW" technology to lower \$.
- “One of the solutions for river cleanup is SALT. To some it is a dirty word in Portland. Salt can and does many things it is a cleanser - a neutralizer, plus ALL KINDS OF OTHER USES. My suggestion would be to drop or lace the bottom of the contaminated area with 50 LB salt blocks (these are salt blocks that are used by ranchers and feedlots that cattle have to have in their diet, THEY ALSO HAVE IODIZED AND SULPHUR SALT BLOCKS). I REALLY BELIEVE that salt blocks would neutralize the contaminated area, and it would eventually disappear!! That is my suggestion and it is worth looking into.”
- “If your recovery plan for the Willamette River uses nature as a major element, then the plan needs to support nature to speed the process up. Fish are natural bio-concentrators and should be harvested in your recovery program to remove toxins from the river. At this time, catching fish is allowed in the Willamette, but the fisherman is advised not to keep the fish residing in this area year around because they have too high of levels of toxic substances in them. If you catch and release the fish, you are not removing the toxins from the environment. If you have a repository for the caught resident fish, the toxic substance can be taken out of the environment and concentrated for disposal. This can be set up like the BPA’s northern Pike minnow program that is run by the Oregon Dept. of Fish and Wildlife in the state of Oregon. As the fish are given to ODFW to be disposed, the fisherman would be rewarded by either a dollar amount or by supplying them with safe hatchery trout. Sturgeon would be one of the resident fish not allowed to harvest in this plan. This plan: 1) May shorten the time to clean up the toxins loose in the water. 2) Removes toxic substances from the environment. 3) Improves the health of the resident fish by removing the sick and old. 4) Provides food or financial support for fishermen by offsetting the cost of fishing which makes the cost of buying a fishing license more cost effective. In other words, helps

the poor to be able to afford to fish for food. 5) Helps the ODFW to be a governmental agency that helps the poor instead of only helping the rich (those who can afford to fish and release their fish).

### **EPA Response**

The NCP (March 8, 1990) which provides the blueprint for CERCLA response actions, encourages the consideration of innovative technologies. It notes: *“Today’s rule [NCP preamble and regulation] also contains an expectation on the use of innovative technologies that EPA developed in response to numerous comments calling for increased emphasis on the diversification of treatment technologies used in site remediation. EPA supports such diversification and expects that it will generally be appropriate to investigate remedial alternatives that use innovative technologies when such technology offers the potential for comparable or superior treatment performance or implementability, fewer or lesser adverse impacts than other available approaches, or lower costs for similar levels of performance than demonstrated technologies. EPA considered a range of technologies as well as innovative technologies as part of the remedy investigation/feasibility study.”*

The process for identification and screening of remedial technologies is presented in Section 2.4 of the feasibility study report (USEPA 2016b). The remedial technologies that were retained for further consideration are based on site-specific data. The identified technology types are initially screened for technical implementability and then expanded into lists of potentially applicable process options, which are then screened further for effectiveness, implementability, and relative cost. Remedial technologies and process options that were retained were assembled into remedial alternatives as presented in Section 3 of the feasibility study report.

Many of the comments recommend that in-situ bioremediation (in-situ treatment with Micro-Bac International’s M-1000H\* microbial solution or other proprietary products) be included in the remedy; however, this remedial technology was not considered to be feasible because many of the contaminants at the Site are not biodegradable (heavy metals) or are very persistent in the environment (PCDD/F, PCB, and pesticides). In addition, many in-situ technologies present implementability concerns in a large river system. Although in-situ bioremediation technologies were not retained as a feasible remedial technology, biological degradation is an important part of the enhanced natural recovery and monitored natural recovery, which are the general response actions for the largest area of contaminated sediment in the preferred alternative. EPA does not consider in-river placement of iodized or sulfur salt blocks as a feasible technology for remediation at the Site because placement of salt along the top of the sediment bed would alter the chemistry in the biologically active zone of the river sediment and within the water column, which would be harmful to the benthic and aquatic communities. In addition, EPA is not aware of any remedial actions utilizing salt to successfully remediate sediment contaminated with the PCBs, PAHs, dioxin/furans, and DDX, which are the focused contaminants of concern at the Site. Encapsulation of contaminated sediment is a technology type that was included in the selected remedy, both on-site capping of sediment and river banks and in providing containment at off-site disposal facilities and landfills.

Dredged sediment containing any Resource Conservation and Recovery Act hazardous wastes, pesticide residue, or PTW related to non-aqueous phase liquid will be evaluated to determine the need for and extent of treatment appropriate for off-site disposal. While low temperature thermal desorption and solidification/stabilization are ex-situ treatment options considered in the feasibility study, other treatment options were retained and may be considered before the material is disposed as part of the

remedial design. EPA will consider such changes and will continue to communicate with the community on this issue.

Removing fish that have bioaccumulated COCs in their tissue was not identified as an appropriate and effective removal technology for addressing sources of contamination within the Site because other removal technologies (mechanical dredging) are much more effective in achieving the RAOs. EPA is interested in mechanisms to reduce the impacts of fish consumption advisories (which apply only to resident fish) on fisher communities. After issuance of the ROD further community outreach on cleanup, particularly, advisories, EPA will further our efforts to do outreach to fisher communities, including tribal, low-income, minority, and immigrant communities to identify such mechanisms and implement them where feasible.

### 2.15.2 Consider Suggestions for Alternate Established Technologies or Products

#### Comment Summary

Four comments were received suggesting the use of particular technologies at the Site. One was from a representative of an environmental product for dealing with contaminated sediment and had concerns over the specific references to proprietary products (AquaBlock and AquaGate) in the proposed plan. Another was from a proponent of induced polarization as a fast, cost-efficient geophysical tool for contaminant delineation to aid in the cleanup efforts. Another was from a purveyor of thermal treatment technology for use in treating PCBs, PAHs, dioxins, furans, and DDT. The final comment was from Volcano Partners LLC for use of their patented vitrification process and product (Cement-Lock® and Ecomelt®) to segregate and treat dredged sediments at their on-site facility.

#### EPA Response

Descriptions of general remedial technologies evaluated and the screening of these technologies can be found in feasibility study report Sections 2.3 and 2.4 (USEPA 2016b). These sections describe the use of sorptive and sorptive-reactive material as well as thermal desorption and vitrification, which are retained site-wide remedial technologies as shown in Table 2.4-1a-c of the feasibility study report.

The proposed plan (USEPA 2016c) describes specific products used in the assumptions for the cap designs for cost estimate transparency purposes and does not imply that these proprietary products are the only ones to be considered during the design phase. Excluding reference to AquaGate™ would affect the assumptions built into cost estimates and negatively alter the transparency of any associated cost estimates.

Geophysical mapping technologies, such as induced polarization, used to survey and refine contaminant extent in Portland Harbor can be considered during the design phase based on implementability, effectiveness, and cost among other considerations. However, the ROD does not contain details of potential alternative technologies that may be used for field investigations as well as remedial actions. EPA will extend consideration to technology alternatives (including additives, thermal treatment, and geophysical mapping) during the remedial design phase and will consider input from vendors, if appropriate.

### 2.15.3 Incorporate Relevant Sustainability Studies and Guidelines

#### Comment Summary

Several commenters cite the September 2016 *Portland Harbor Sustainability Project* report (NERA 2016), prepared by AECOM, NERA Economic Consulting, and SEA Environmental Decisions for a group

of PRPs. The report evaluates the three pillars of sustainability: environmental quality, economic viability, and social equity. The evaluation is based on:

- Analysis of cleanup costs and construction times
- Net environmental benefit analysis
- Human health risks.

The project surveyed community stakeholders and developed social indicators or metrics to score each alternative in terms of “stakeholder group values” and found progressively lower scores for environmental, economic, and social impacts for the larger alternatives. The commenters believed that these results should have carried more weight in EPA’s evaluation of alternatives.

In addition, ExxonMobil suggests EPA has not followed its own guidance or White House directives. Attachment 1 to ExxonMobil’s comments provides a *Path Forward for a Sustainable Remedy at Portland Harbor Superfund Site*, which outlines specific studies that should be conducted prior to finalizing the ROD.

### **EPA Response**

The NCP provides the overall blueprint that EPA follows for response selection and implementing a CERCLA response. As noted in the August 2, 2016 memorandum titled: “Consideration of Greener Cleanup Activities in the Superfund Process” (Greener Cleanup Memo):

- *“Selecting and documenting greener cleanup activities in decision documents. Where greener cleanup activities are selected as part of the response action, they should be specifically addressed in the decision document. They should be treated in the same manner as any other integral part of alternatives being evaluated, consistent with the NCP (40 CFR 300.415 for removal actions and 300.430 for remedial actions) and CERCLA Guidance. For example, the decision document should explain how various alternatives were evaluated and provide the basis for the response action’s selection; this explanation should include how specific greener cleanup activities are incorporated as part of alternatives and how the greener cleanup activities were evaluated considering the NCP nine-criteria evaluation for remedial actions and the three-criteria NTCRA evaluation.”*

EPA’s two threshold criteria for selecting a Superfund remedy are: (1) overall protection of human health and the environment and (2) compliance with applicable or relevant and appropriate requirements of federal and state environmental laws. Once these two criteria are satisfied, EPA determines the best balance of tradeoffs among the alternatives with respect to balancing criteria, one of which is short-term effectiveness, and modifying criteria, including community acceptance, which includes a wide spectrum of often competing concerns. EPA conducted a detailed analysis of individual alternatives against the evaluation criteria, following guidance that is consistently applied among Superfund sites across the nation. The guidance cited by the commenter (*Safe and Sustainable Water Resources: Strategic Research Action Plan 2016-2019 11, 22* and *Sustainable and Healthy Communities: Strategic Research Action Plan 2016-2019 14*) are issued by EPA’s Office of Research and Development and not the EPA Office of Solid Waste and Emergency Response (now Office of Land and Emergency Management) which issues cleanup-related guidance documents. Neither CERCLA nor the NCP require a sustainability study such as what the commenter submitted as part of the remedy selection process. Sustainability related considerations may be applied to a selected remedy to enhance environmental

protections consistent with recent green remediation guidance. A cost-effectiveness evaluation is not a requirement for a feasibility study but rather is considered for selecting a remedy.

As noted in the 2016 Greener Cleanup Memo, EPA uses the CERCLA process. The portions of a sustainability study may or may not fit within the nine-criterion remedy evaluation framework. EPA is committed to consider activities that may minimize the environmental footprint of the response. EPA noted in the Greener Cleanup Memo:

- *“The decision document should present the specific activities’ basis, including a concise discussion of how the greener cleanup activities will reduce the environmental footprint. Consistent with the NCP, considerations raised by other criteria cannot supplant 40 CFR 300.430 (9)(iii)’s two threshold criteria (protect human health and the environment and comply with applicable or relevant and appropriate requirements (ARARs) unless a waiver is justified.) EPA does not have to select the alternative with the minimum environmental footprint. Rather, project managers and other decision-makers should consider greener cleanup activities in the context of a complete balancing criteria analysis for evaluating alternatives after determining that the alternative meets the threshold criteria of protectiveness and compliance with ARARs.”*

EPA acknowledges that remedial actions should incorporate greener cleanup activities wherever possible. These measures may include best management practices to reduce emissions of greenhouse gases and reduce emissions and/or exposure to pollutants such as diesel particulates, nitrous oxides, and sulfur oxides during implementation of the remedy. As described in Section 4.2.2.5 of the feasibility study report (USEPA 2016b), a green remediation plan will be required during remedial design, consistent with the EPA Region 10 *Clean and Green Policy*. An outline for the plan is provided in Appendix M of the feasibility study report. As noted above, EPA acknowledges the need to incorporate sustainability measures.

The four main goals identified by ExxonMobil in its *Path Forward for a Sustainable Remedy at Portland Harbor Superfund Site* include the following topics. For further responses to comments for each of these, see the referenced sections of this responsiveness summary:

- Reduce the uncertainty in exposure assumptions (Section 2.19.3)
- Improve stakeholder buy-in (Section 2.28 and 2.36)
- Validate the site conceptual model (Sections 2.12 and 2.21)
- Allow time for source control to be verified and equilibrium background levels to be established (Section 2.17)

## 2.16 Monitored Natural Recovery

### 2.16.1 The Proposed Plan Relies Too Heavily on MNR

#### Comment Summary

A total of 324 comments were received that spoke to this topic. Hundreds of comment postcards were received that followed a format with four or five talking points.

The most commonly seen form comments include:

- “The plan relies mostly on “Monitored Natural Recovery” which leaves polluted material in the river and simply monitors it over time”
- “The draft plan contains far too much MNR.”
- “The draft cleanup plan relies too much on “monitored natural recovery,” a “do nothing” strategy that leaves pollution in the river in the hopes that it will either be covered over or flushed downstream.”
- “Monitored natural recovery, with or without enhancement has not been shown to be effective and therefore EPA needs to reduce its use and include provisions in the Record of Decision for contingency actions if monitoring data indicate unsatisfactory performance results.”

Other representative personal comments include:

- “The 1,876 acres of “monitored natural recovery” will still contain PCBs, dioxins, and furans that “stay in the environment for a long time,” according to EPA’s proposal (page 3).”
- “I don’t understand the logic of natural remediation when most of the toxics have been in place since WWII. That is by my calculations nearly three quarters of a century, only slightly older than I am. One would think that if the PCBs and dioxin were amenable to resolving by leaving them alone, they would be of no consequence.”
- “I think the plan relies too much on “monitored natural recovery.” A wait-and-see approach has not been working since heyday of river contamination in the 20th century; and it won’t work any more quickly now. Given the ongoing disturbance of sediments by ocean-going shipping, the contaminants continue to emerge into our river. This wait-and-see, do-nothing approach is inadequate and will make all of us liable to the spread of contaminants downstream, into the Columbia River, and thence into the Pacific Ocean. This must not happen. The problems with “monitored natural recovery” are thrown into high relief when we consider the issue of who would be doing the monitoring 100 or 200 or 300 years from now. The toxins will still be toxic; will there be any responsible party present to monitor the recovery and upgrade the practices as necessary in case “monitored natural recovery” proves ineffective? Better to clean it up now, while we have the capacity to do so, and be done with it so subsequent generations are not faced with challenges they may not be able to meet.”
- “Expecting nature to fix 86 percent of the river without intervention is a joke.”
- “EPA and Lower Willamette Group found that PCB’s are by far the most hazardous and the most widespread problem of the chemicals found to be in Portland Harbor and present for forty years. For over fifty years, dioxins in the form of Agent Orange and other herbicides were discharged and remain in the river. PAH’s and other oil based chemicals have been in Portland Harbor for over eighty years. It was in the 1930’s that the gas prepared coke was poured into Portland Harbor. The investigating and testing has taken place in the last twenty years demonstrating natural recovery has done little or nothing to remove them or prevent access to them therefore sufficient removal as proposed in the Alternative G should first and foremost be considered the best cleanup plan. These chemicals, left in the river continue pose health threats to humans and

wildlife continuing into the future for generations. In every level or Alternative suggested by EPA methods such as capping allows the contamination to be left in the river.”

- “The concept of monitored recovery is much too passive and basically leaves pollution where it is hoping that there won't be problems in the future. We don't really know what problems have already been caused, yet, it is crystal clear that the pollutants are very toxic to the environment. The plan over-all, relies on letting the pollutants stay where they are while allowing the river to serve as a toxic waste dump.”
- “Clean up methods should not leave persistent contaminants in or adjacent to the Willamette River. Clean up should include source control, include river sources. For the clean up to be considered complete, fish from the Willamette River should be safe for human consumptions at a rate of for greater then 8 oz. of fish per month. Please establish an action plan to limit contaminant spelling during sediment dredging. Please ensure that financial tools are in place in the event of recontamination.”

### **EPA Response**

MNR works when sediments transported from upstream into the Site are cleaner than those that exist at the Site. Natural recovery is likely to occur the fastest in depositional environments after source control actions and active remediation of higher concentration sediment have been completed. During natural recovery, deposition and mixing of cleaner sediments with the sediment bed results in lower surface sediment concentrations at the Site. Additionally, some contaminants degrade to lower, less problematic levels over time. Since recovery is dependent on the deposition and mixing of clean sediment with contaminated sediment, nearby sources of contamination can hinder natural recovery processes. That is one reason that EPA's proposed cleanup plan addresses the high concentration sediments and contaminated groundwater source areas.

The Willamette River is transitional, meaning that sediments move around. Deposition rates at the Site have been estimated based on a series of bathymetric surveys conducted between 2002 and 2009. Other lines of evidence that indicate deposition is occurring include grain size analysis and subsurface to surface sediment concentration ratios. Deposition of sediments occurs in the majority of the river during some point of the year. In other parts of the year, such as during periods of high flow, erosional conditions occur. Erosion also occurs in areas subject to wind- and wake-generated waves such as in nearshore areas. Boat propellers can also cause the sediment to move. Site conditions are conducive for MNR when contaminant concentrations are low and cover diffuse areas (USEPA 2005). These low contaminant concentration areas addressed by MNR for the selected remedy cover approximately 82 percent of the Site. MNR is less appropriate in areas of high concentrations and will occur slower in areas where deposition is infrequent. EPA reviewed the evidence provided in the feasibility study and concluded that MNR is likely to reduce surface sediment concentrations in the low-contamination areas that will remain following active remediation.

MNR requires regular monitoring of sediment, surface water, and biota tissue to assess trajectories toward reaching cleanup goals on a planned timeline. If, based on this monitoring, MNR is not working well or fast enough to meet these trajectories, additional actions may be required to meet the cleanup levels. Any additional action taken will depend on the reason that MNR is not working. If it is determined that there is a previously unknown or new source of contamination, that source would need to be identified and addressed. If MNR is not working as expected due to river conditions, the cleanup plan may need to be amended to require additional remedial action such as dredging or capping.

## 2.16.2 Consider Impacts on the Columbia River from Use of MNR

### Comment Summary

Two comments were received that addressed the potential for impacts to the Columbia River from MNR use at the Site. The comments were from the Portland Audubon Society and stated:

1. EPA should carefully assess and describe potential impacts to the Columbia River resulting from its clean-up strategy. EPA relies on Monitored Natural Recovery across 86 percent of the Site. MNR depends upon a combination of deposition of clean sediment on top of contaminated sediment and dispersal downstream. The feasibility study report and proposed plan fail to characterize how much contaminated sediment is likely to get flushed downstream into the Columbia. While the Willamette will benefit from this strategy over time, the Columbia will pay the price. Notably, the areas directly downriver of the confluence include important Wildlife Areas such as the Sauvie Island Wildlife Area and the Ridgefield National Wildlife Refuge. They also include heavily used public beaches on Sauvie Island. Finally, they include potential NRDA mitigation sites such as the Alder Creek Site that has been developed by Wildlands at the southern tip of Sauvie Island.

EPA's Report, Columbia River Basin: State of the River Report for Toxics 2009, notes that EPA joined other state, federal tribal, local and non-profit partners to form the Columbia River Toxics Reduction Working Group in 2005 with the goal of "reducing toxics in the Columbia River Basin and prevent further contamination." (EPA Columbia River Basin Toxics Report at page 1).

It appears to us that EPA is sacrificing the health of the Columbia River in order to improve the health of the Willamette River by selecting Alternative I, which depends heavily on MNR rather than more environmental protective alternatives that rely more heavily on dredging. In order to meet important toxic reduction objectives on both rivers, EPA needs to evaluate the relative impacts of all alternatives on the Columbia River and incorporate the information into their alternative selection process. EPA should provide clear characterization of how the clean-up plan and specifically MNR is likely to impact toxic loads on the Columbia River, whether that will provide increased risk to humans or wildlife using natural areas and public areas near the confluence, increase risks to humans consuming fish on the Columbia, and how it might impact treaty rights along the Columbia River.

2. EPA should assess the risks presented by previously dredged materials that were removed from Portland Harbor and determine whether current disposal situations are sufficient to protect human and environmental health. For example, Portland Harbor Dredge spoils have been placed on West Hayden Island under the State's "Beneficial Use Policy" based on the incorrect assumption that the Site would be paved over and developed within 5 years. EPA should include in the clean-up plan, feasibility study report, and ROD a review of all contaminated materials that have been removed from Portland Harbor since it was listed under CERCLA, including their current location and whether the disposal scenario is sufficient to meet the standards established to protect public and environmental safety set out in the feasibility study report, proposed plan, and ROD. Sites that are not sufficient to meet the goals should have their own clean-up requirements incorporated into the plan. It is deeply disconcerting that EPA has allowed so much contaminated material to be redistributed outside of Portland Harbor prior to adopting a remedy and ROD, and we believe that in doing so, EPA has potentially distributed

toxic materials that pose a risk to people and wildlife over a far greater geographic area than was originally contaminated.

### **EPA Response**

Please refer to responses to comments in Sections 2.16.1, 2.16.3, and 2.2.102 of this document, as well as ROD Section 9, 11, 12.8, 14.2.7, 14.2.10, and 14.4 regarding reduction of the reliance of the selected remedy on MNR, and the overall monitoring approach to verify that contaminant loading to the Columbia River and Multnomah Channel is being reduced.

It should be noted that EPA likely will not support the placement of contaminated material dredged from the area subject to this ROD nor the downtown reach in the Columbia River, if it exceeds human health PRGs or any of the ecological PRGs for bioaccumulation or other relevant exposure scenarios that would apply to unconfined in-river disposal. EPA will now review Clean Water Act § 404 permits in detail within and in some cases upstream of the Site to ensure that such work is consistent with the ROD.

### **2.16.3 MNR Mechanisms and Performance Are Not Understood**

#### **Comment Summary**

Numerous comments were received relating to the performance of MNR as a technology at the Site. One commenter noted that the dynamics of sediment surface chemistry also have a direct effect on the calculation of RALs and evaluations of natural recovery and that these time-dependent RALs and their linkage to natural recovery estimates are one of the key characteristics of the selected remedy (i.e., they define where active remediation will take place).

Several commenters noted that a hydrodynamic sediment transport model should be used to evaluate natural recovery processes and support remedial decision making. It was noted that can tie together snap shots in time and reproduce underlying processes. It was also noted that the use of numerical fate and transport models is supported by EPA guidance. Finally, it was noted that without a model, the lines of evidence based on only limited empirical data result in a significant overdesign to compensate for uncertainties. Without a model, it is difficult to understand the causes of the changes in condition identified by future monitoring. Not using a model in a complex system like the Portland Harbor Site is directly contrary to current professional best practices.

One commenter stated that MNR presents several advantages because it is less invasive and more cost-effective and sustainable than other remedial alternatives. MNR, for example, requires less construction and infrastructure than other treatment options, and thus is usually much less disruptive of communities than active remedies such as dredging or in-situ capping, and it results in no contaminated materials being transported through communities.

Two commenters stated that heavy reliance on MNR as part of the site remedy was not supported by the science and that the historic record shows, contaminated sediments continue to remain exposed decades after the contamination originated. The commenters stated many of the contaminants found in Portland Harbor (including PCBs, heavy metals, dioxins, and furans) are extremely slow to degrade and therefore MNR is not an appropriate remedy to address these contaminants. Relying on MNR across such a large percentage of the Superfund Area will result in continued exposures of humans and wildlife to contaminants, recontamination of areas that have been decontaminated, and increased contamination of the Columbia River downstream from the Superfund Site.

One commenter noted that although there is evidence to suggest that over time clean sediment from upriver will deposit on the river bottom covering up contaminated sediments, the potential for exposure through bioturbation, earthquakes, floods and propeller wash remains. The commenter also noted the Willamette River does not offer the correct natural conditions to favor effective use of MNR, and should MNR be a component of the site remedy, monitoring should be conducted annually to ensure progress is acceptable and contingency plans should be included in the ROD for further action if progress is not satisfactory. Finally, one commenter questioned what exists showing MNR to be sufficient for remediation of the majority of the Site, and how was this natural recovery modeled?

### **EPA Response**

MNR is a fundamental component of the remedy. As one commenter noted, the proposed plan (USEPA 2016c) properly employs MNR for a significant portion of the Site and is well supported by site conditions, the NCP, and EPA guidance. EPA's final remedy includes approximately 1,774 acres of MNR at the Site. As noted in many of the comments, a detailed hydrodynamic and sediment transport model was developed as part of the remedial investigation/feasibility study activities conducted by LWG.

EPA commissioned external expert reviews of this model, which identified several shortcomings that limit its usefulness in predicting sediment transport within the Site. A more detailed discussion of the limitations associated with the Portland Harbor hydrodynamic and sediment transport model is provided in Appendix H. An evaluation of predicted versus measured changes in sediment bed evaluation concluded that the Portland Harbor hydrodynamic and sediment transport model tends to over predict deposition, particularly in areas where erosion is measured. As a result, the utility of the contaminant fate and transport model developed for the Site to evaluate MNR is limited. In the feasibility study, outcomes greater than  $t=0$  were not quantitatively evaluated using the hydrodynamic and sediment transport model because the results are not quantitatively accurate and absolute or relative comparisons among quantitatively inaccurate outcomes, is not helpful. However, quantitative evaluations of empirical data (trends in sediment deposition and fish tissue), where available, were undertaken.

A number of commenters noted that many of the evaluations presented in the feasibility study report (USEPA 2016b) were based on data that are not representative of current conditions and that the evaluation did not consider recent sediment data collected throughout the Site by Kleinfelder and in Swan Island Lagoon by Geosyntec showing MNR is occurring. Other commenters stated that the feasibility study did not properly evaluate fish tissue data collected in 2002, 2007, 2011 and 2012 that show MNR is occurring.

Regarding the fish tissue data, EPA conducted an evaluation of fish tissue data collected in 2011 and 2012 and compared that to fish tissue data collected in 2007. EPA did not include fish tissue data collected in 2002 in the evaluation because the 2002 data were comprised of composite fish tissue samples from both sides of the river. While the 2002 data may be relevant for risk assessment purposes, it obscures known site/source signatures that are on one side of the river. The 2007 fish tissue data were comprised of composite fish tissue samples from one side of the river. The 2011 and 2012 fish tissue data were comprised of individual fish tissue samples collected from each side of the river. An evaluation of temporal trends (of any media) requires consistent collection methodology over the evaluated time period. As a result, the evaluation was limited to 2007, 2011, and 2012 results collected from specific reaches and specific sides of the river. The results of the evaluation showed that in all but two instances (RMs 4E and 7E), concentration declines were not statistically distinguishable from zero.

The Kleinfelder and Geosyntec sediment data sets may be further considered in remedial design. Newly collected data sets will be evaluated to update areas of the Site where remediation is warranted and assess whether any areas have already achieved sediment cleanup levels. As noted above, EPA considered multiple lines of evidence to evaluate the effectiveness of MNR and concluded that MNR would be an effective remedy for approximately 1,900 acres of the Site. EPA agrees that MNR presents several advantages because it is less invasive and more cost-effective and sustainable than other remedial alternatives. However, MNR alone is not expected to result in a remedy that is protective of human health and the environment. As a result, MNR has been paired with the active remediation of contaminated sediments through capping and/or dredging.

Some commenters questioned whether MNR is adequate to address metals and bioaccumulative chemicals that do not degrade appreciably in the environment and whether MNR was appropriate due to the continued exposures of humans and wildlife to contaminants, recontamination of areas that have been decontaminated, and increased contamination of the Columbia River downstream from the Superfund Site. The commenters also stated that the primary natural recovery process is deposition of cleaner material over the top of contaminated sediments and, as a result anthropogenic and natural processes such as flood events and propeller wash may erode newly deposited sediments thus limiting the effectiveness of MNR. EPA recognizes the uncertainty associated with the long-term effectiveness and will rely on a robust long-term monitoring program to confirm the effectiveness of MNR.

Overall, EPA expects that some natural recovery of sediment contaminant concentrations may have occurred at the Site since the remedial investigation/feasibility study database was developed, and that it will continue to occur, especially following completion of source control efforts and remediation of the most heavily contaminated sediment bed. The process for implementing remedial action is designed to directly accommodate this recovery. Prior to any active remediation, the sediment bed will be re-sampled to update the active remediation footprint, and incorporate any natural recovery that has occurred. The updated remedial footprint, using contemporary surface and subsurface sediment data, will be used to apply the decision tree.

## 2.17 Monitoring and Contingency Actions

### 2.17.1 Provide Timelines and Metrics for Success

#### Comment Summary

A total of 1,333 comments were received on this topic. Almost all (98 percent) were received as form emails that said:

- "EPA should set much clearer timelines and metrics for success including setting an explicit date by which Portland Harbor specific fish consumption advisories will be lifted."

The remaining comments were personal and include:

- "Set metrics-based benchmarks for water quality improvement in the lower Columbia River."
- "Include a clear plan for monitoring the success of cleanup activities with a contingency cleanup plan if natural remediation proves insufficient towards meeting cleanup goals."
- "Monitoring is an invaluable evaluation tool that can be used to assess the completeness of remedy implementation, remedy effectiveness, and the need for contingency actions. The proposed cleanup plan does not clearly define how site progress will be evaluated and how

compliance with regulatory requirements and cleanup objectives will be measured. Without clearly outlining compliance criteria or metrics, a meaningful assessment of the project progress cannot occur. In addition, if the cleanup does not proceed as expected, there is no contingency plan in place to ensure protectiveness for human health and the environment. The ROD must include more adequate detail on how progress and compliance will be measured. More clear and specific information is needed on interim and long-term metrics, how and where they will be monitored or evaluated, timelines, and contingencies.”

- “The National Remedy Review Board made it pretty clear that it expects the US EPA to set multiple clear deadlines, including a deadline for lifting the Fish Consumption Advisory, in this cleanup. How are people expected to weigh the effectiveness of various alternatives if a clear date is not set for lifting the Advisory? The lack of a clear timeline to lift the Fish Consumption Advisory will also make it difficult to hold EPA or PRPs accountable for implementing the cleanup plan in an effective matter, and meeting the specific objective included in the ROD. At the most basic level, this cleanup is about the ability for people to consume resident fish without increasing their cancer risk! EPA should select an Alternative that gets us to a specific date for lifting the Fish Consumption Advisory.”
- “In a data-driven economy, EPA must set clearer timelines and metrics for clean-up success. If we can't measure it, then it didn't happen.”
- “To fully evaluate the proposed action, the plan should, at a minimum, include:
  - A schedule of environmental sampling, accounting for seasonal and environmental variation, to ensure that the expected variance in response variables is accounted for and can be incorporated into the final analysis;
  - The environmental variables to be monitored and the methodology to be used;
  - A statistical design to monitor if actual changes in the chosen metrics, outside of natural variation, are occurring within the Site. There are numerous designs applicable, however, the BACI (Before-After-Control-Impact) may be the most useful when considering both the MNR and ENR sites;
  - A definition of “recovery” or “failure” that incorporates changes over time in the monitored environmental variables. This definition should also include a proposed timeline in which these desired outcomes would be observed if the plan is working, and;
  - A defined timeline and response if MNR sites are not recovering as expected or desired, wherein they could be converted to ENR sites to meet the goals of the Superfund proposed plan within the proposed timeline.”

### **EPA Response**

Timelines and metrics for many components of the cleanup will be further developed in the remedial design, after issuance of the ROD. Prior to remedy implementation, sampling will be conducted to establish baseline conditions for sediment, surface water, pore water, biota, fish tissue, and river banks. Sampling of these will continue through construction of the remedy, after construction is complete and in the long term. Sampling locations and frequency will be determined during design and in the future in

monitoring plans. It is premature to make those determinations in this ROD since the locations and frequency will depend on the purpose of the monitoring. Different needs for monitoring will require different sampling and monitoring plans.

EPA expects that fish consumption advisories may be less restrictive once the cleanup has been completed. However, since the relationship between sediment and fish tissue is not well understood, it is premature to establish a date for when this may occur. Further, fish consumption advisories likely will not be lifted completely due to larger watershed issues (such as mercury) and also because sediment concentrations of PCBs in “clean” areas upstream of Portland Harbor Site are higher than the acceptable risk range based on conservative risk estimates. Over time, it is expected that implementation of the selected remedy, source control actions on the part of DEQ in the Portland Harbor and watershed-wide (including upstream areas) actions will reduce or eliminate the need for fish consumption advisories. However, at this time it is not possible to determine a specific date when this will occur. Please see Section 2.3 of this responsiveness summary for more information about fish consumption advisories.

### 2.17.2 Ensure Fish Tissue Monitoring Is Conducted

#### Comment Summary

Twenty-nine comments were received that requested that contamination in fish was monitored. Roughly 75 percent were form comments received by email that stated:

- “The general goals and design characteristics/requirements of the fish tissue monitoring need to be specifically listed in the R.O.D.”

The remaining comments were similar in content and include:

- “In addition to other fish, lamprey must be included in the monitoring. Lamprey are a critical component in the local ecosystem and to native diets and culture. Peoples who depend on lamprey are especially susceptible to heavy metals that are not cleaned from the CERCLA sites, as heavy metals are bioaccumulated in fatty tissues and lamprey are highly fatty. Exclusion of lamprey monitoring and reporting is a direct dismissal of the local indigenous peoples and their large presence in the Portland region.”
- “A monitoring program should begin as soon as possible to establish a baseline monitoring levels of contamination in fish tissue is a must to determine benefits of biota and effectiveness of remediation overtime. We want monitoring of small/young/large mature fish (Carp, Sturgeon/Bass to see that they exhibit less contaminates over the phase of the cleanup. We want general goals and design characteristics/requirements of fish tissue monitoring listed record of decisions. We want to ensure all sampling and analytic methods are consistent throughout the duration of monitoring.”
- “Fish contamination needs to be monitored to assess the changes with time and over space, beginning with a monitoring program to establish a clear baseline.”
- “Testing of fish tissue needs to begin and continue throughout the construction phase A baseline for fish tissue contaminant levels needs to be established as soon as possible and continue throughout the construction process so the effects of the remedies can be reflected in the testing. The method of testing should be consistent between agencies and PRPS and should be established in the ROD so results can be compared over time to measure remedy success or failure.”

## EPA Response

EPA agrees that monitoring is a crucial part of the cleanup plan. Fish tissue sampling began in the remedial investigation and will continue through implementation and monitoring of the remedy. A monitoring plan will be developed after the ROD during remedial design and will outline the sampling, including fish tissue sampling, to be conducted to establish baseline concentrations. Additionally, it will include the monitoring to be conducted during and following construction to evaluate how the cleanup is achieving the cleanup levels, targets, and remedial action objectives.

The monitoring plan will include details of the fish sampling such as species, numbers, and size of fish. Monitoring will focus on resident fish that pose the greatest risk to human health, likely to include carp, bass, and catfish. Monitoring may also include tracking resident species to get a greater understanding of where their exposure occurs within the Site.

Lamprey and other fish that migrate through the Site, such as salmon, are not good indicators of reductions in tissue concentrations from contamination at the Site or success of the cleanup because these fish spend time away from the Site. However, impacts to migrating fish from the cleanup activities will be assessed and addressed through mitigation measures to minimize adverse impacts to these species. The monitoring plan will include a detailed description of the methods to be used in accordance with EPA's guidelines for establishing and meeting data quality objectives. It will be submitted to the National Marine Fisheries Service for review of the adequacy of sampling design and procedures for safe fish handling during construction to prevent injury to listed species.

### 2.17.3 Ensure In-River Monitoring Before, During, and After Remediation

#### Comment Summary

A total of 746 comments were received on this topic, and roughly 97 percent were in the form of a multi-bullet postcard having one bullet that read:

- "Include ongoing monitoring and cleanup upriver and downriver from the Site."

The remaining comments were personal comments that generally echoed that sentiment. Commenters also requested that monitoring begin immediately and last past cleanup and that there be a plan for monitoring that includes soil, air, water, and fish contamination. The use of buoys was also suggested.

Representative comments include:

- "Monitoring of the superfund site, all 11 miles, needs to start now and continue past the completion of the cleanup. They need to implement habitat restoration and that also should be monitored for years after to make sure that the area stays viable and animals and plants continue to live there."
- "EPA's proposed plan does not include a rigorous monitoring plan, nor alternatives that would be required if the monitoring indicates that the cleanup is not proceeding as planned. EPA must require long-term financial assurance that the monitoring will occur and the public will have access to the monitoring data over at least the next 20-30 years. Further, the cleanup plan must include mid-course corrections so we don't need to waste any further time studying options."

- “Collect baseline data on soil, air, water, and fish contamination as soon as possible. Require independent monitoring throughout the remediation period until clean, healthy levels are achieved.”
- “I would also encourage EPA to use water quality monitoring data buoys as a form of providing live information regarding water quality for EPA and Oregon DEQ for contractor compliance with permitting agencies.”

### **EPA Response**

Monitoring is a crucial part of EPA’s cleanup plan. Significant remedial design sampling to determine existing baseline levels of contamination and to design the cleanup will be conducted before the construction begins. Ongoing monitoring will be conducted to track the performance of the cleanup toward achieving the remedial action objectives and cleanup levels, and 5-year reviews will be conducted of the cleanup as required by CERCLA. Baseline sampling will include areas upstream and downstream of the Site.

DEQ has lead responsibility for identifying and controlling upland and upriver sources of contamination that may impact the river. Under this program, DEQ is addressing contamination in upland areas that include upland and in-river sources along the downtown reach of the river and contaminated groundwater. As sources further upriver are identified, EPA assumes those upriver sources will be addressed as well. Similarly, DEQ would address downriver sources of contamination to make sure they are not contributing to contaminant loading to the Columbia River.

During active remediation activities (such as dredging, capping, placement of clean sediment for ENR) there will be monitoring in the construction area as appropriate. The cleanup activities performed in the river will need to comply with water quality standards near where the activity is taking place. Air samples may be collected to make sure contaminants do not exceed worker health-based concentration levels in air. If contaminant levels exceed water or air quality standards, the work will be modified, and additional controls will be taken as needed. In addition, collection of sediment, surface water, pore water, and fish tissue samples will be collected as specified in a monitoring plan developed after the ROD.

Following construction, there will be long-term monitoring until the cleanup levels are achieved and beyond. The long-term monitoring program will include sediment, river banks, surface water, pore water, and fish tissue samples from upstream, within, and downstream of the Site. Passive samplers may also be used to supplement fish tissue data as a surrogate for fish tissue. Data on contaminant levels will be used for multiple purposes, such as to determine if natural recovery is taking place as expected or if any additional actions are required to achieve the cleanup levels on the planned timeline, track if fish tissue concentrations are decreasing, and monitor if the caps are effectively containing the contaminated sediment and/or groundwater. Data on contaminant levels in fish tissue will also help inform when and how the fish consumption advisory or other restrictions could be relaxed.

Long-term monitoring will also include regular inspections of the whole remedy, including sediment caps, to make sure they are effectively containing migration of COCs, in the proper place, have the required thickness and type of capping material, are achieving RAOs such as pore water standards, and are functioning as intended. Inspections may be required after natural events, such as earthquakes or floods, and manmade events such as boat collisions or violations of land use restrictions. Monitoring and maintenance of the caps would be required in perpetuity.

## 2.17.4 Require Quality of Life Monitoring throughout Remediation

### Comment Summary

Forty-seven comments were received requesting “quality of life monitoring.” About 45 percent were received as form emails and stated:

- “EPA needs to require installation of environmental and quality of life monitoring during the construction phase, with the PRP’s covering the cost. This provision needs to be a required element and clearly stated.”

Most of the remaining comments were personal comments that often went into more detail, stating that independent air, water, light, and noise monitoring should be conducted during cleanup to protect impacted neighborhoods. Requests related to this monitoring included expedited laboratory turnaround times for results (funded by polluters), results available to the public quickly (perhaps on a website), and for the requirement to be documented in the ROD.

Representative comments include:

- “During the time of active cleanup air and water quality monitoring is necessary to ensure health of workers and adjacent neighborhoods or any neighborhoods affected by construction.”
- “Monitoring of air, water, odor and noise, daily, used while in construction phase with quick testing turnaround and adjustments, particularly when near affected communities for quality of life.”
- “Livability and Environmental monitoring. Monitoring of both air and water needs to occur at regular intervals downriver of construction work including into the Multnomah Channel, Columbia River to keep excess contamination in check. Care should be taken especially to monitor PCB release into the air. An action plan should be in place to immediately address excess contamination of air or water. The ROD should include a requirement for monitoring of the environment as well as regular EPA reports online or by other easily accessible means to the community about specific activities during construction, as well as air and water monitoring results. Laboratory turnaround times for results should be as expedient as possible and funded by polluters. Monitoring of lights, odors, noise and all other possible issues that could affect livability of surrounding residential neighbors should also be required in the ROD. Neighbors should have an easy means of contacting EPA such as an 800 number, if livability problems need to be reported.”
- “I would like independent air, water, light, and noise monitoring during cleanup - protecting impacted neighborhoods.”
- “Monitor air, water, odor and noise, daily, while in construction phase with quick testing turnaround and adjustments, particularly when near affected communities for quality of life. Twenty-four (24) hour dredging could be acceptable with those caveats.”

### EPA Response

The ROD describes the final selected remedy and the underlying information that supports the decision. Specific details of how the selected remedy will be implemented are often not included in the ROD but are developed in the remedial design which begins after the ROD is signed. EPA will develop a

monitoring program during the remedial design phase and will consider public input as the plan is being developed. A comprehensive monitoring program to establish the baseline for sediment, fish tissue, surface water, and (as needed) air will be conducted at the beginning of remedial design. Concerns about air quality, noise, odor, light, and other potential community impacts will also be considered and addressed to the extent possible. Exceedances of health-based standards may result in additional controls being put in place so that construction impacts are mitigated to the extent practicable. EPA will provide contact information for community members to raise complaints or concerns during construction.

### 2.17.5 Ensure Costs for Monitoring in Perpetuity Are Included

#### Comment Summary

Thirty-five comments were received on this topic. Twenty comments were included in form emails and stated:

- “This remedy will have features that must be maintained in perpetuity and thus analyses need to account for a longer time frame in estimating costs and benefits.”

Several other comments noted that the costs needed to be estimated over a period of at least 100 years. Other comments expanded on this theme and included:

- “Since many of the pollutants (PCB’s, dioxans/furans, DDT’s, and metals) are known to resist degradation by natural processes the ROD needs to require and include the costs of monitoring pollution levels and solving problems for a greatly extended period at the expense of the polluters.”
- “We must utilize capping technology, where clean materials are put over contaminated sediments to hold them in place only where it is technically feasible, and where it will never impede navigation. We must also realize that capping has costs for the long-term with perpetual monitoring that adds to the cost of such measures.”
- “We must realize that capping has costs for the long-term with perpetual monitoring that adds to the cost of such measures.”
- “Time frame for cleanup needs to be 100 yrs. Minimum. When EPA suggests that the timeframe, the usual practice for estimating a remedy’s long-term cost is to assume a 30-year period of analysis but this is inadequate. In the late 1970’s, Portland citizens believed that the Willamette had been finally cleaned up. Since then, the city spent 14 years to correct that inadequate assumption by building the “Big Pipe” costing \$1.5 billion dollars. Thirty years is an inadequate time allotment unless repeating the Superfund process seems satisfactory. In addition, with a minimum of 14 areas of capping to monitor and maintain, thirty years of sustenance seems very insufficient.”
- “Long term effectiveness and permanence need careful consideration. Given the proposed plan’s reliance on monitored or enhanced natural recovery, the time frame of monitoring needs to be extended out beyond 100 years or more. Many of the toxins in the river show little evidence of degrading in the many years they have already been in the river. If they are to be controlled in perpetuity by capping or similar means, provisions need to be made to maintain the integrity of these barriers as long as the toxins remain active.”

- “Time frame for estimated costs needs to be longer, at least 100 years, recognizing that the remedy includes monitoring in perpetuity.”
- “Because this cleanup will have features that must be maintained for decades to come, the analyses and monitoring plans need to account for a longer timeframe in estimating costs and benefits than is currently being contemplated.”

### **EPA Response**

EPA recognizes the implications of long-term monitoring on the overall cost of the remedial alternatives. The alternatives retained for detailed analysis all have sediment containment and capping components that will require perpetual maintenance and monitoring. However, evaluation of long durations of maintenance and monitoring is generally not necessary for comparative evaluation between alternatives, because of the effects of cost discounting in later years under present value analysis. The period of analysis for the feasibility study report (USEPA 2016b) is assumed to be 30 years because the increase of present value cost due to small periodic expenditures for maintenance and monitoring after 30 years is minimal relative to the accuracy range of the estimates.

As part of the sensitivity analysis in the feasibility study report (Appendix N), a timeframe of 100 years was also evaluated to assess the costs of long-term monitoring and maintaining the caps beyond the 30-year period used to compare costs between alternatives. As illustrated in Tables N-1 and Figures N-1a through N-1f, while the non-discounted costs for each alternative increase as the period of analysis increases from 30 years to 100 years, the present value (discounted) cost increase is very minimal after year 30.

## **2.17.6 Address Issues with Site-Specific Background**

### **Comment Summary**

Comments pertaining to the calculation and use of background concentrations were submitted by 10 local businesses, many of which are PRPs. The individual comments are too long to repeat verbatim here, but the specific issues are captured below:

- Sediment background dataset is very limited, collected over too many years, and should include data from the downtown Portland reach.
- Background data were incorrectly discarded as outliers and background concentrations were incorrectly calculated because the tests to identify outliers assumed a normal distribution.
- Background sediment concentrations should be expressed as a range and should consider a sediment equilibrium value.
- Accurate characterization of site-specific background is needed, and EPA’s evaluation has resulted in unrealistically low background values such that PRGs are less than concentrations in stormwater and other ongoing upstream and upland sources.
- Background concentrations need to be developed for surface water and fish tissue.
- Background concentrations should be developed for all COCs.
- Background concentrations need to be reevaluated prior to issuing the ROD so the selected remedy is “achievable.”

## EPA Response

Proper development and use of a site-specific background dataset is an important element in the remedial alternatives evaluated for the feasibility study. In consultation with EPA, DEQ, and the tribes, LWG selected the reference area for determining background sediment concentrations. As described in Section 7.2 of the remedial investigation report (USEPA 2016a), this area is comprised of the upriver reach of the lower Willamette River, extending from the upstream end of Ross Island (just upstream of the downtown Portland area) to approximately 2.5 miles above Willamette Falls (RM 15.3 to 28.4). A total of 48 sediment samples in the background reference area were analyzed for PCBs as Aroclors and 33 sediment samples were analyzed for PCBs as congeners. Of these PCB samples, four were identified as outliers and removed from the data set. Sample counts for the remaining COCs analyzed ranged from 48 to 71 sediment samples. The data set primarily contains data from five investigations performed from 2004 to 2007, and one investigation performed in 1999. Although the data were collected over several years, this span of time is not unusual for large Superfund sites consisting of multiple investigations.

Sediment data from the downtown Portland reach of the lower Willamette River were not included in the background dataset. One reason is that reports submitted to EPA by LWG noted that the Site is subject to tidal influence, which results in a flow reversal of the lower Willamette River through at least the downtown reach. Site-related sources have also been identified in the downtown reach such sediment sample results from this reach of the Willamette River are not representative of non-site related data. A background reference area upstream of the downtown reach was selected so that the background data are more representative of the entire Willamette River watershed, and not an adjacent area with a greater potential of in-river and upland sources.

To identify and address outliers, EPA used an approach that is consistent with the recommendations of the ProUCL Version 5.0.00 User Guide and Technical Manual. The ProUCL User Guide and Technical Manual directly discuss the issue of identifying and addressing outliers and provide EPA's most recent, comprehensive discussion of this issue. These documents recommend the use of statistical tests such as: (a) Rosner's and Dixon's tests to identify outliers; (b) the use of graphical displays, including box plots and Q-Q Plots, to compare against and along with the results of the statistical tests; (c) the consideration of historical and current site and regional information to identify suspected outliers (extreme values coming from the far tails of the data); and (d) the performance of decision-making statistical computations with and without the suspected outliers before decisions to exclude data/datum as outliers are made. Further justification for this approach is provided in EPA's dispute decision letter to LWG dated March 24, 2015 (USEPA 2016d) [AR Doc #500011627] (Appendix A of this document).

Using the recommended approach in the ProUCL guidance, EPA compared the results of statistical outlier tests performed by ProUCL Version 5.0.00 with the visual observations of outliers and found that the two approaches generally found the same outliers. For example, the statistical approach identified five outliers from the PCB Aroclor dataset and the visual approach identified four. In addition, EPA used SCOUT to conduct a more robust statistical test of the PCB Aroclor data, and this approach identified 8 potential outliers, four extreme and four intermediate, and after reviewing the results of this analysis, EPA concluded that only the four extreme values were outliers. Thus, EPA selected fewer outliers than were identified in the statistical tests it employed. EPA also considered the effects of removing successive outliers for PCBs as Aroclors, PCBs as congeners and DDx. Before a decision to exclude datum as outliers, EPA compared statistical endpoints of datasets which included and excluded the suspected outliers.

Based on these evaluations, EPA removed four outliers from the Aroclor data set, and then corrected the upper prediction limit and upper confidence limit for organic carbon content using a methodology developed by LWG and approved by EPA. With the exception of performing the SCOUT analysis, EPA performed the same analysis for all indicator contaminants. EPA excluded data for background determinations for the following indicator contaminants: arsenic, total chlordane, DDx, BEHP, total PAHs, PCBs as Aroclors, PCB as congeners, Total PCDFs/PCDDs, and zinc.

EPA did not assume a normal distribution of data but instead, consistent with its guidance, removed outliers after appropriately analyzing the data. As recommended by the ProUCL Technical Guide, EPA used raw data to run outlier tests and initiated the ProUCL analysis without transforming the data. EPA then used ProUCL Version 5.0.00 to compute statistics and identify how well the data fit various distributions, such that EPA not only evaluated representations of data that were normally distributed but also evaluated other distributions identified by ProUCL. ProUCL is programmed to automatically model and graphically display the data to determine the appropriate distribution data and statistical methods for the selected distribution(s). EPA guidance generally cautions against using a lognormal distribution unless the data are only mildly skewed. In cases where the data are more than mildly skewed, the use of lognormal distributions tend to accommodate outliers and yield inflated or distorted values for upper confidence limits, upper prediction limits, and upper tolerance limits.

EPA selected single values for background concentrations and did not use as a range of concentrations to represent background concentrations as suggested by EVRAZ Inc. EPA recognizes that background concentrations are variable but a single value is needed for comparison purposes. EPA does endorse the concept of equilibrium, however, the necessary information (sediment trend data) is not available to conduct an equilibrium evaluation in the long-term. EPA has developed background concentrations consistent with EPA policy and guidance. EPA has further looked at the sediment traps deployed in the upriver reach, which corroborate with the values developed from the upriver sediment.

In response to commenters who stated that EPA's background evaluation resulted in unrealistically low background values, such that PRGs are less than concentrations in stormwater and other ongoing upstream and upland sources, EPA followed the current guidance and procedures to select background concentrations applicable to the Site. To minimize the effect of recontamination and continue to reduce fish tissue concentrations after cleanup, EPA and DEQ are committed to controlling upstream and upland sources to reduce ongoing impacts to the Willamette River.

EPA did not develop background concentrations for surface water and fish tissue in the feasibility study report (USEPA 2016b) because there were insufficient data to statistically compute background concentrations. Further, since human health surface water PRGs are based primarily on ARARs, EPA would need to waive the ARAR, which means information would be needed to show that achieving the ARAR is technically impracticable, there is no such information at this time.

Neither the remedial investigation nor the 2016 feasibility study presented background concentrations for all COCs in sediment because the remedial investigation report concluded there were insufficient detections to determine background concentrations for 2,3,7,8-TCDD eq, aldrin, dieldrin, DDT, Lindane, and TBT. The exception is TPH-diesel in which a background concentration was calculated in the remedial investigation report, Appendix H, but was inadvertently omitted from Table 2.2-9 in the 2016 feasibility study report. The background concentration is 61 milligrams per kilogram, which would not change the selection of the PRG, which is 91 milligrams per kilogram, since the risk-based number is greater than background.

Based on careful analysis of available information, EPA believes that the sediment background concentrations selected are representative of the entire Willamette watershed, and the selected remedy is achievable. The selected remedy requires active cleanup to the RALs and then relies on ENR and MNR to further reduce contaminant concentrations to meet the cleanup levels. Post-construction monitoring will be conducted to evaluate the effectiveness of ENR and MNR and its ability to achieve remediation goals.

Additional information regarding EPA's position on the establishment of background concentrations is provided in EPA's March 24, 2015 Letter to Bob Wyatt of LWG, "Re: Dispute Decision Regarding Lower Willamette Group Dispute dated August 26, 2014" [AR Doc #500011627], EPA's position to LWG Dispute Issues 1g and 1h, and LSS Dispute Issues 8 and 11a (Appendix A of this document).

## 2.18 Overall Protection of Human Health and the Environment

### 2.18.1 The Preferred Alternative is Too Protective

#### Comment Summary

Comments on the overall protectiveness of the preferred alternative in the proposed plan were received from five commenters. Several commenters expressed concerns that the level of protectiveness is set too high without any scientifically defensible basis and that EPA is undermining the Oregon Health Authority's and Agency for Toxic Substance Disease Registry's definition of protectiveness (especially as it pertains to fish consumption advisories) with no "credible data." Several commenters stated this level of protectiveness is unobtainable due to upstream contamination and the surrounding urban environment. Some commenters sighted unreasonable fish consumption assumptions as the source of the excess protectiveness. Additionally, commenters were concerned that capping was considered less protective, the comprehensive benthic risk approach was "abandoned," and protectiveness was based on unsupported benthic risk.

Commenters suggested that Alternatives B, C, and D were unjustifiably eliminated, arguing several individual factors showed these alternatives to be similar to other alternatives. They also suggested natural recovery should be considered as part of the remedial action protectiveness for Alternatives B and D to boost the alternatives' overall protectiveness. Some suggested that since no alternatives completely addressed ecological risk, Alternative B benefits may exceed its disadvantages. The Swan Island Optimized Alternative was also referenced in several comment letters as having protectiveness equal to Alternative I for the Swan Island Lagoon. One commenter stated EPA did not provide the basis for whether the increased costs and risks (during transport) for the dredging and upland disposal associated with Alternatives E, F, G, and I are worth the environment benefit for those alternatives compared to Alternative B.

#### EPA Response

The NCP describes how alternatives should be developed in the feasibility study through the establishment of remedial action objectives and preliminary remediation goals that protect human health and the environment and defines what is generally protective risk levels (40 CFR 300.430(e)(2)). The NCP further describes how the detailed analysis of alternatives should be conducted. 40 CFR §300.430(e)(9). Regarding overall protection of human health and the environment, the NCP (40 CFR §300.430(e)(9)(iii)(A)) states "Overall protection of human health and the environment draws on the assessments conducted under other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs." EPA's alternatives evaluation was consistent with the NCP and drew from these other criteria. While it is not the intention or desire to

"undermine" local agencies, the NCP defines what level of risk is protective and it is those standards that EPA must consider in making CERCLA remedy decisions.

Alternatives B and D were not "abandoned" due to factors outlined by the commenters. Assertions by commenters that alternatives were eliminated based on individual factors do not accurately represent the actual process. While those factors were considered, the final determination was based on a broad-based evaluation as discussed in LWG Dispute Issue 1a (Appendix A of this document). Due to the evaluation results discussed in the dispute response, it is not consistent with guidance to select Alternative B simply because no alternatives fully meet environmental protectiveness RAOs, at the completion of construction. We anticipate that the RAOs and cleanup levels, including the fish tissue levels will be achieved at the end of the cleanup. All alternatives exhibited different levels of certainty as to meeting the RAOs at the completion of the construction. All alternatives meet or fail to meet different RAOs to different extents with various levels of uncertainty. Alternative C was deemed to be too similar to Alternatives B and D, and so it was not retained for further evaluation.

Regarding the comment that EPA did not provide the basis for whether the increased costs and risks associated with Alternatives E, F, G, and I are worth the added protectiveness of those alternatives compared to Alternative B, the 2016 feasibility study report (USEPA 2016b) presents EPA's evaluation of each alternative. Although Alternative B would have the least impact to the community, the feasibility study states that due to the reliance on MNR and ICs, Alternative B does not meet interim targets established for risks and hazard indices in a reasonable timeframe. Alternative B, in conjunction with adequate upland and upriver source control measures, would not achieve numeric human health and aquatic life water quality criteria and drinking water MCLGs and MCLs. EPA's analysis also shows that Alternative B does not sufficiently reduce the load of contamination from sediment to surface water such that water quality ARARs could be achieved.

EPA did not quantify and evaluate natural recovery for alternates because natural recovery is a complex natural process that can be easily disrupted by uncontrollable environmental factors. As such, EPA sought to reduce the uncertainty surrounding natural recovery by relying on active remedial technologies to the extent feasible to increase the certainty that natural recovery will be effective and shorten the timeframe over which it is ostensibly being relied upon. Difficulties in estimating and relying on MNR are also discussed in the MNR Response.

EPA does not consider capping to diminish the protectiveness of any alternative. Capping was considered not to be effective in some areas based on site characteristics such as the need for maintenance dredging, anchoring or others. Capping also has associated long-term maintenance and monitoring costs, which can make it less cost effective, and depending on future use, potentially a less permanent cleanup technology in some areas. However, it is considered an effective remedial approach for many areas, which is why it is considered throughout much of the Site.

Several commenters expressed concerns that the use of benthic risk in association with protectiveness was not appropriate or technically based. EPA's response on this issue is addressed in LWG Dispute Issue 1b (Appendix A of this document). Some commenters questioned why the comprehensive benthic risk area was not used. EPA has responded to this comment in LWG Dispute Issue 1a (Appendix A of this document). The response to benthic risk (Section 2.34.1 of this responsiveness summary) can also be referenced for additional information.

As noted in the feasibility study report, interim targets for risks and hazard indices were used to evaluate the potential for achievement of PRGs in a reasonable time frame among other matrices. For RAO 5, the interim target is based on multiplying the RAO 5 PRG by an order of magnitude to account for further reductions due to MNR. In addition, the post-construction interim target for RAO 5 was set at a 50 percent reduction in the area posing unacceptable benthic risk because risks to the benthic community are based on a population level rather than individual level effect and is considered a target to which the benthic population, as a whole, can be stressed and still recover.

EPA notes that the protectiveness for the Swan Island “optimized remedial alternative” provided by the Swan Island group is similar with respect to the time to achieve protectiveness to that provided by the preferred remedy. The ROD outlines measures to provide flexibility, based on empirical data, in remedial design to evaluate which remedial technologies are appropriate in that area.

## 2.18.2 The Preferred Alternative is Not Protective Enough

### Comment Summary

Contrary to the argument that the Preferred Alternative was too protective, other commenters (Portland Audubon Society and the CAG) expressed concerns that the preferred alternative is not protective enough and failed to meet threshold criteria. Additionally, the commenters suggested that the preferred alternative would leave the rivers heavily contaminated for decades and sacrifice human and environmental health for low cost for PRPs. Commenters summarized and sighted RAOs not being met for all alternatives and ICs and MNR were called unproven approaches.

### EPA Response

After reviewing and considering public comments, EPA selected a remedy that addresses more contamination with dredging and capping (Alternative F Modified). EPA evaluated post construction reductions using SEDCAM Modeling results, which showed that the selected remedy is protective within a reasonable timeframe given the uncertainty in the model. See also Sections 2.1, 2.3, 2.7, and 2.31 of this responsiveness summary and LWG Dispute Issue 1h (Appendix A of this document).

ICs will be in place to protect human health which aligns with NCP guidance. Contrary to commenter assertions, ICs and MNR have been effectively used at numerous sites. Fish advisory ICs are discussed in detail in Section 2.28 of this responsiveness summary.

## 2.19 Long-term Effectiveness and Permanence

### 2.19.1 Long-term Effectiveness Was Not Properly Evaluated

#### Comment Summary

Multiple commenters suggested that EPA’s long-term effectiveness evaluation did not conform to CERCLA, NCP, and/or EPA guidance because it was not quantitative or detailed. They disagreed with the use of interim targets saying that they were contrary to guidance. Union Pacific asserted, “the record provides no basis for EPA to assume that one alternative will perform better than another with respect to meeting cleanup goals, ARARs, or interim targets within a ‘reasonable time frame.’” Over the long-term, LWG took issue with the evaluation indicating that Alternative B would not meet chemical-specific ARARs ‘in a reasonable timeframe,’ sighting that “... EPA has no quantitative method to assess the long-term outcomes of the alternatives.” Commenters also asked EPA to clarify what is the referenced “reasonable timeframe” to achieve cleanup levels. Additionally, LWG was concerned that Alternative D should not have been ranked low for long-term effectiveness as a result of EPA’s goal to “maximize permanence through removal of highly contaminated sediment” because guidance states that mass

removal is not an appropriate way to evaluate sediment remediation alternatives; rather the evaluation must address reduction in risk.

Commenters critiqued the evaluation for not considering river equilibrium with ongoing contaminant loading from upland and upstream, and having a statistically flawed approach for calculating background concentrations. LWG argued that the Lower Duwamish proposed plan and Grasse River ROD evaluated sediment transport and background loading (respectively), and incorporated those considerations in to final decisions; thus, EPA should do the same. EPA was asked to recognize that source control could not eliminate contaminant inputs from stormwater. The Swan Island Group pointed out, "... long-term success of sediment remedies relies on source control and reducing external sources of contamination."

In addition to the assertion the interim targets are not in-line with NCP guidance, commenters expressed several other concerns that interim targets are not relevant for assessing long-term effectiveness because:

- The evaluation focuses "... almost exclusively on SWACs immediately post-construction ... [with] no quantitative estimates of long-term alternative outcomes ...."
- There are better ways to evaluate long-term effectiveness. "EPA could have easily devised empirically based estimates of long-term outcomes of the alternatives without resorting to complex computer models [,]" but "... ignored recent data (provided by LWG) that could be used in long-term effectiveness evaluation"
- The evaluation assumes "... that EPA's PRGs are met immediately [after construction]. ... This ... does not reflect the likelihood that river conditions will rapidly regress to background levels which exceed EPA's PRGs and health-based goals."
- "... the effectiveness analysis fails to consider natural recovery during or after construction and as augmented by enhanced natural recovery that EPA relies upon to meet PRGs in the long term."
- "To analyze relative long-term effectiveness and cost-effectiveness, EPA must provide some estimate of the SWACs and risk reduction in the years following completion of construction."
- No alternative could be shown to meets all interim targets and all but Alternative G failed to meet at least half of the interim targets.

Commenters expressed concern that EPA is not adequately considering long-term effectiveness or residual risk beyond construction completion and lacks a technically defensible projection of long-term performance. They indicate the impact of ENR was not included in the long-term effectiveness evaluation, and question how EPA can claim that MNR cannot be quantitatively estimated, while assuming PRGs will be met through MNR in 30 years, and determining that Alternative B and D will achieve cleanup goals. Additionally, commenters suggest EPA should take natural attenuation into account that is likely to occur during planning and construction phases, and suggests EPA should not assume that post-construction SWACs will remain constant.

LWG commented that Post Construction SWACs/risk estimates are "useless to assess long-term effectiveness of the alternatives" due to:

- Inconsistent PRGs
- Spatial Scales inconsistent with risk assessments
- Flawed SWACS
- Flawed Risk Assessment
- Errors in EPA's surface water analysis

Multiple other parties summarized EPA's long-term effectiveness analysis and expressed concern that only Alternative G came close to meeting RAOs, and recommended that a more aggressive option than G was needed to adequately protect human and environmental health. Additionally, they argue that long-term effectiveness and permanence should be prioritized over short-term effectiveness and cost.

### **EPA Response**

EPA evaluated long-term effectiveness in accordance with the NCP. In accordance with the NCP (40 CFR §300.430), alternatives were assessed for the long-term effectiveness and permanence they afford, based primarily on:

- “Magnitude of residual risk remaining from untreated waste or treatment residuals remaining at the conclusion of the remedial activities”
- “Adequacy and reliability of controls such as containment systems and ICs that are necessary to manage treatment residuals and untreated waste.”

As described in Section 4.1.5 of the feasibility study report (USEPA 2016b), long-term effectiveness and permanence refers to the expected residual risk and the ability of an alternative to maintain reliable protection of human health and the environment over time, once PRGs are achieved. This criterion includes the consideration of residual risk that will remain on-site following remediation and the adequacy and reliability of engineering (remedial technologies) and ICs to manage those risks posed by treatment residuals and/or untreated wastes.

EPA's evaluation of long-term effectiveness was both quantitative and detailed. The evaluation of risk reduction from each alternative was conducted by estimating the post construction sediment concentration, estimating the fish tissue concentration through the food web model and estimating the residual risk based on a comparison to PRGs. The impact of ENR was not considered in the estimate of post construction sediment concentrations in the feasibility study, even though it is acknowledged that ENR would reduce risk also. Post construction sediment concentrations/ SWACs are discussed in Section 2.7.2 of this responsiveness summary.

The selected remedy, Alternative F Modified reduces more risks than Alternative I at the end of construction and minimizes reliance on ICs.

Most related comments are focused on the desire for quantitative determinations of the time that various alternatives will achieve ARARs or PRGs. However, that topic relates specifically to short-term effectiveness, not long-term, in the NCP, and is one of four items to be considered in evaluating that criteria:

“(E) Short-term effectiveness. The short-term impacts of alternatives shall be assessed considering the following:

- (1) Short-term risks that might be posed to the community during implementation of an alternative;
- (2) Potential impacts on workers during remedial action and the effectiveness and reliability of protective measures;
- (3) Potential environmental impacts of the remedial action and the effectiveness and reliability of mitigative measures during implementation; and
- (4) Time until protection is achieved.”

All alternatives would be considered protective at the end of construction with the use of ICs to reduce fish consumption to acceptable levels. The balance of trade-offs was central to selecting a remedy with a balance of active remediation and natural recovery to ensure a faster pace of risk reduction with additional certainty relative to permanence of the overall remedy. For more information about the role of fish advisories, see Section 2.28.2 of this responsiveness summary.

As described in the MNR response (Section 2.16 of this responsiveness summary), the environmental processes that support natural recovery are present in the river (incoming sediment loads promoting burial and dilution, contaminant declines through dispersion, and degradation of some compounds) and will be hastened when in-river and upland sources of contamination are eliminated. However, the complex nature of the Site and the limited data set to demonstrate the rate of improvement in water, sediment, and fish tissue contaminant concentrations restrict the ability to make quantitative determinations of contaminant declines following remediation based on empirical analyses or mechanistic modeling. Therefore, estimates of the post-remediation condition are used to gauge environmental improvement from remedial action. The active remediation components of the selected remedy do not achieve PRGs in all areas after construction, and rely on natural recovery and robust post-remedy monitoring of water, sediment, and fish tissue contaminant concentrations to establish attainment of remedial cleanup levels, source control effectiveness ongoing evaluations, or the need for additional remediation through the five-year review process.

### 2.19.2 Risk Management Was Not Properly Considered

#### Comment Summary

A number of comments were received that noted that EPA did not consider risk management in the selection of COCs, development of remediation goals and the development and evaluation of remedial action alternatives. It was stated that EPA failed to perform a necessary risk management step between the remedial investigation and feasibility study phases consistent with EPA guidance.

It was noted that EPA’s chosen remedy did not reflect risk management principles and that risk management decisions and remedial cleanup levels should reflect specific uses at different portions of the Site. For example, no narrowing of COCs, pathways, media or receptors or refining of exposure assumptions was performed. It was further stated that EPA identified an unreasonable number of PRGs without consideration of the factors driving risk at the Site or what is achievable through a sediment remediation even though EPA develop RALs for a set of focused PRGs. Finally, one commenter stated

that although PRGs for the  $1 \times 10^{-4}$  and  $1 \times 10^{-5}$  risk levels were presented in Appendix B of the feasibility study report, no discussion of these PRGs was provided in the feasibility study report.

It was also noted that there is very little difference in residual risk estimates between Alternatives B and I for most COCs. Given the very conservative assumptions used to calculate PRGs, differences in estimated risks by a factor of 2 or less are not significant.

One commenter stated that EPA failed to make valid risk reduction decisions when evaluating and selecting a preferred alternative and has failed to accurately communicate to the resident fish-eating public regarding their ability to eat resident fish from the harbor once the remedy has been completed. EPA has not clearly disclosed the actual risk reduction that would be achieved if the preferred alternative were performed but instead has made inaccurate and confusing statements about the ability to eat fish following remedy implementation.

Another commenter stated that EPA failed to compare risk reduction for its preferred alternative to background risks. For example, a comparison of background (upstream) and Site smallmouth bass PCB concentrations shows that only a 2 or 3-fold decrease in Site-wide sediment concentrations is needed to reach equilibrium conditions. One commenter stated that it is important to provide context for considering the expected benefit of the alternative when evaluated in terms of the number of advisory fish meals following the cleanup relative to advisory fish meals due to background risk so the public can understand the actual anticipated benefits of EPA's action.

Regarding the magnitude of risk reduction, it was noted that there is little risk reduction between Alternatives B and I in EPA's feasibility study report and that if EPA's alternatives assessment was not otherwise flawed, Alternative B would properly be the "knee of the curve." The substantial increase in costs for minimal or insignificant risk reduction between Alternatives B and I is not acknowledged in EPA's feasibility study report or the proposed plan.

It was also noted that EPA's fish consumption risk calculations are not meaningful for evaluating protectiveness because none of the alternatives in the proposed plan will result in a material increase in the number of meals of resident fish from Portland Harbor that are safe to eat. The risk assumed from eating resident fish in the Harbor is calculated based on 228 meals per year for the subsistence fisher model and up to 78 meals per year for the recreational fisher model. The assumed improvement in fish consumption-related risk for all alternatives ranges from 2 meals to 10 meals per year. This number of additional meals is within the error band of the analysis, and is essentially meaningless when EPA's goal for unlimited consumption, without fish consumption advisories, is 78 to 228 meals per year. It was further noted that there is no obvious reason to prefer Alternative I (7 years of 0.6 fish meals to achieve 5 fish meals per year) to Alternative B (4 years at 0.6 to achieve 3 per year) or, for that matter, to Alternative G (19 years at 0.6 to achieve 10 per year). EPA's preference seems wholly arbitrary.

Another commenter stated that EPA has given no indication that it has similarly considered the benefits from eating fish in establishing its very conservative "fish meals per 10 years" amounts.

Another commenter noted that EPA stated in the feasibility study report that "the existing advisories might not be sufficiently effective in protecting human health since the current recommended rate of one meal per month [12 meals/year] for the general population may not be sufficiently protective of consumers." They further commented that EPA should consider that the conflict between the Oregon Health Authority advisory and EPA's BHHRA (Kennedy/Jenks 2013) indicates EPA's risk estimates may be incorrect. At a minimum, EPA should coordinate with Oregon Health Authority to provide clear,

credible, and consistent public health information. EPA should also explain its advisory in light of the U.S. Food and Drug Administration's threshold for PCBs in fish sold in supermarkets of 2 parts per million, which is more than 1,000 times higher than EPA's cleanup goal of 0.3 parts per billion (ppb) in resident fish tissue.

Several commenters referred to risk management in the context of the NCP and EPA guidance. For example, it was noted that risk management in the Superfund program requires consideration of the advantages and disadvantages of cleanup alternatives and a balancing of trade-offs. As noted in the NCP preamble, the likelihood of exposure actually occurring should be considered when deciding the appropriate level of remediation to the degree that this likelihood can be determined. In addition, it was noted that EPA's 2005 Sediment guidance, states that a risk management process should be used to select a remedy designed to reduce the key human and ecological risk effectively. Finally, it was noted that it was telling that the phrase risk management is never used in the feasibility study report or the proposed plan.

Finally, it was noted that EPA's chosen remedy is not based on risk reduction/risk management principles. EPA notes that fish consumption is the major contributor to human health risk but does not consider the probability that dredging remedies will result in an increase in fish tissue concentrations for years during and after the completion of any remedy. The risk of releases during dredging is clearly present despite use of BMPs due to the large volume of dredging, duration (7) and high production rates assumed in the feasibility study report.

### **EPA Response**

EPA adequately applied risk management in its remedy selection process given site-specific circumstances and information. Risk management is not done at one point in the process and generally is not given its own section in a feasibility study report or other decision document. One of the 11 principles for managing contaminated sediment sites is to select site-specific, project-specific and sediment-specific risk management approaches that will achieve risk-based goals. EPA has complied with this principle at the Site by focusing the cleanup on those areas that have the highest levels of toxic and persistent contaminants and whose cleanup will have the most impact on reducing risks to human health and the environment. EPA believes the best cleanup approach is one that sufficiently reduces risk in the areas where contamination is highest to allow for MNR to achieve cleanup levels in a reasonable time frame. The alternatives evaluated in the feasibility study report (USEPA 2016b) relied on ICs, MNR, ENR, containment, treatment, removal and disposal to varying degrees.

Some examples of how risk management was applied at the Site are discussed below. The baseline human health and ecological risk assessments identified 110 contaminants that potentially posed unacceptable risk. As shown in Table 2.2-2a through e of the feasibility study report, EPA utilized risk management to select 64 COCs based on the results of the risk characterization. EPA further considered risk management through the selection of focused COCs for the purpose of conducting the feasibility study. As noted in Section 3.4.1.1 of the feasibility study report, focused COCs are those that the distribution encompasses the majority of the spatial extent of contaminants posing the majority of the risks as identified in the baseline risk assessments. Finally, focused COCs allowed more efficient evaluation of the contamination within the Site during the feasibility study, though of course PRGs govern the success of the final cleanup.

Remedial action levels selected for evaluation in the feasibility study were developed for each of the focused COCs by plotting surface sediment concentrations and the relationships between RAL

concentrations and resulting site-wide SWACs. “RAL curves”) were developed by plotting acres remediated against the post remediation SWAC. This evaluation facilitated identification of the “knee of the curve” for the relationship between area and post remediation SWACs. The purpose of this evaluation is to optimize the remedial footprint by developing alternatives that target areas with the highest levels of contamination and utilize MNR throughout the remainder of the Site. This significant reliance on MNR to reduce risks across the vast majority of the Site in areas where contaminant concentrations – and thus the relative risk – are lower than within the SMAs is application of risk management.

Regarding the selection of PRGs, as was noted in the comments, EPA considered a range of risk-based PRGs. For example, risk-based PRGs for PCBs presented in Table B3-5 ranged from 0 to 60 µg/kg. However, the actual PRG for PCBs as presented in Table 2.2-5 is 9 µg/kg which is background based and greater than sediment PRGs based on a hazard index of 1. Unlike EPA’s risk range of  $1 \times 10^{-4}$  to  $1 \times 10^{-6}$ , EPA does not use a risk range for non-cancer risks. As a result, EPA does not have the same flexibility to adjust the risk range as it does when evaluating cancer risk.

EPA disagrees that it failed to accurately communicate to the resident fish-eating public regarding their ability to eat resident fish from the harbor once the remedy has been completed and that EPA has not clearly disclosed the actual risk reduction that would be achieved if the preferred alternative were performed. For example, the proposed plan (USEPA 2016c) provided detailed information regarding the allowable number of fish meals per 10 years for a range of remedial alternatives and fish consumption exposure scenarios. The proposed plan notes that estimating the number of acceptable fish meals at the end of construction is not a precise calculation, but that such calculations are useful to allow for a comparison of the outcomes of the different alternatives.

Regarding a comparison of background (upstream) and Site smallmouth bass PCB concentrations, the proposed plan notes that Biota samples from within the Site exhibited greater concentrations for most contaminants than those seen in background biota samples that were collected from the upriver reaches and above Willamette Falls. However, the data are insufficient to compute defensible background concentrations for biota tissue.

Regarding consideration of the likelihood of exposure actually occurring when deciding the appropriate level of remediation, EPA notes that the exposure pathway that poses the greatest risk to human health is the fish consumption exposure pathway. Fish consumption is known to occur throughout the Site. As a result, it is appropriate to select and implement a sediment cleanup that focuses on this key exposure pathway. Regarding the risk of releases during dredging and the probability that dredging based remedies will result in an increase in fish tissue concentrations for years during and after the completion of any remedy, EPA acknowledges that some short-term effects are likely during implementation of the remedy even with the use of BMPs and other measures to reduce these impacts. The evaluation of short-term effectiveness considered explicitly in the feasibility study report. For example, the feasibility study report notes that Alternative B has the shortest construction duration and thus would have the least impact to the community, workers, and the environment during construction. Conversely, the Alternative G would have the longest construction duration and, thus, would have the most impact to the community, workers and the environment during construction.

Regarding consideration of the benefit associated with eating fish, this type of assessment is outside the scope of a risk assessment conducted under CERCLA.

Regarding fish consumption advisories issued by the Oregon Health Authority, EPA disagrees inconsistencies between the assumptions used in the HHRA and the criteria that Oregon Health Authority uses to establish fish advisories indicates that EPA's risk estimates are incorrect, rather they have different purposes and methodologies. Similarly, the U.S. Food and Drug Administration's threshold for PCBs in fish sold in supermarkets of 2 parts per million is not relevant due to differences in statutory purposes and requirements. However, EPA agrees that coordination with the Oregon Health Authority is required to provide clear, credible, and consistent public health information. Additional information regarding the use of risk management is provided in the response to LWG Dispute 1r (Appendix A of this document).

Additional information regarding the development of remedial cleanup levels is provided in the response to LSS Dispute Issue 11 (Appendix A of this document).

### 2.19.3 The Exposure Scenarios Are Too Conservative

#### Comment Summary

Several commenters stat that the exposure scenarios do not reflect realistic exposure frequencies for recreational beach users and fishers and, as a result, the PRGs are too conservative. It was stated that the Portland Harbor human health risk assessment was based on unrealistic assumptions about the habits of anglers who are the critical receptors, substantially overstates the actual risk and therefore calls into question all of EPA's risk management decisions for the Site. In addition, the unreasonable conservatism and questionable methodology extend to the development of SWACs and RALs.

It was noted that EPA's evaluation was inconsistent with the NCP because EPA did not consider the likelihood of reasonable maximum exposures actually occurring. The NCP preamble states that the likelihood of the exposure actually occurring should be considered when deciding the appropriate level of remediation to the degree that this likelihood can be determined. For example, EPA concluded that it is reasonable to assume someone's sole source of fish - up to 228 meals per year for subsistence fishers - is resident fish caught in the harbor - no anadromous fish, no fish caught elsewhere and no store-bought fish. EPA presents no evidence that any actual sub-population like this exists anywhere near Portland Harbor.

The commenter further stated that EPA's multiple conservative assumptions were then combined using a deterministic approach that does not account for variability and uncertainty in angler exposures. Consequently, EPA's risk estimates represent extremes that are not representative of the vast majority of Site anglers, and perhaps no member of the fishing population. It was noted that EPA's risk estimates fall at the extreme tails of the distributions of PCB cancer risk and non-cancer hazard (at or above the 99th percentile) and that even with these conservative assumptions, for approximately 90 percent of subsistence anglers and over 95 percent of recreational anglers, current cancer risks and non-cancer hazards are at or below EPA's interim targets of  $10^{-4}$  (cancer) and hazard index of 10 (non-cancer).

One commenter stated that the risk assessment assumptions must bear some relationship to reality for them not to be arbitrary. If they are not realistic, EPA arbitrarily and capriciously replaces sound science with unrealistic assumptions, in violation of CERCLA and the APA. Region 10's failure to consider and incorporate current data, and its multiple unrealistic exposure assumptions are well beyond "protective" and do not result in the accurate estimation of potential risks in Portland Harbor. The use of unrealistic data constitutes arbitrary and capricious agency action. As a consequence, the risk assessment information does not provide realistic information upon which to evaluate remedial

alternatives and to base remedial decisions, and EPA's risk assessment therefore does not satisfy NCP requirements.

The commenter also stated that EPA used assumptions that are unrealistic with respect to the habits of anglers who are the critical receptors, which results in the further overstatement of the actual site risk. EPA also did not follow its own 2013 BHHRA (Kennedy/Jenks 2013) in several important aspects of remedy selection, changing without explanations several key exposure assumptions that almost certainly resulted in additional overstatement of actual risk.

Despite selecting a remedy to address fish consumption risk, EPA acknowledges that its BHHRA risk scenarios contain uncertainty in the assumptions made regarding angler practices and behaviors, such as the amount of whole uncooked fish consumed and the proportion of resident vs. migratory fish consumed. In the absence of accurate information about angler behaviors, EPA relied on multiple conservative (worst case) and unsupported reasonable maximum exposure assumptions that have resulted in flawed PRGs for fish consumption (RAO 2). For example, EPA assumed: 99th percentile fish consumption rates (up to 281 meals per year) and exposure durations; resident species comprise all of the subsistence and recreational angler diets and half of the tribal angler diet; 100 percent of consumed fish come from the Study Area; and no contaminant loss due to cooking and preparation (such as filleting). These multiple conservative assumptions were then combined using a deterministic approach that does not account for variability and uncertainty in angler exposures. Consequently, EPA's risk estimates represent extremes that are not representative of the vast majority of anglers using the Site, and perhaps no member of the fishing population. If additional, realistic exposure assumptions are taken into account and applied to a scientifically valid probabilistic model, risks for the majority of the anglers are currently at or below EPA's interim targets (cancer risk of  $1 \times 10^{-4}$  and non-cancer hazard index of 1).

The hypothetical fisher is assumed to eat nothing but resident fish from the Willamette River. The fisher does not eat salmon or other anadromous fish, does not catch and consume fish from outside the Site and does not consume store bought fish. In addition, EPA does not take into consideration key uncertainties such as preparation and cooking methods.

It was specifically noted that the PRG for cPAHs is based on exposure scenarios that are unrealistic and overly conservative. The exposure scenarios do not reflect realistic exposure frequencies. For example, recreational beach exposure frequency of 94 days per year is based on best professional judgement. In contrast, the Lower Duwamish Waterway used an exposure frequency of 64 days per year based on a King County survey that was considered an overestimate because it was based on beaches with greater amenities than the Lower Duwamish Waterway. Similarly, the tribal direct contact exposure scenario is overly conservative. EPA adopted the assumption that a person would fish at the Site for 260 days per year for 70 years and during every single visit would cover his or her hands and forearms with sediment when pulling up fishing lines or anchors. The commenter stated that these assumptions are not supported by information presented in the remedial investigation report (USEPA 2016a).

In addition, it was noted that EPA's approach improperly assumes that direct contact with sediment may occur everywhere in Portland Harbor without consideration to variations in land uses, site conditions and public access. Several commenters stated that EPA should rely on current and future site uses and security protocols, which prevent direct contact risks to human health. The ROD should reflect the realistic risk of direct contact with contaminated sediments and based risk-management decisions on that reality. Risks from direct contact with sediment do not exist in places that people cannot access. In addition, it was noted that for the recreational fisher, EPA has assumed that anglers spend all of their

time fishing in a one-mile segment of the river. Many locations along the river are not accessible to the public except by boat; whether by boat or from the shoreline, it is highly improbable that someone catches 80 fish meals per year for 30 years from the same location.

Regarding ecological risk, it was noted that ecological risk is managed on a population, not individual, basis. So even if a home range is within a river mile, the contiguous population is exposed over a larger area, and, therefore, post-construction risks should be evaluated on a site-wide basis. Overall, the commenters stated that the risk assessment assumptions are not merely conservative but wholly unrealistic and contrary to the “conservative but within a realistic range of exposure scenarios” recommended by the NCP.

### **EPA Response**

The exposure scenarios evaluated in the baseline human health and ecological risk assessments are based on a reasonable maximum exposure scenario consistent with EPA guidance. As described in the BHHRA (Kennedy/Jenks 2013), fish consumption rates from published studies were used to describe the range of reasonably expected exposures relevant to the different populations known to occur in the Portland Harbor area. Three different rates were evaluated: 17.5 grams per day (approximately 2 eight ounce meals per month), 49 grams per day (approximately 6.5 eight ounce meals per month), and 142 grams per day (19 eight ounce meals per month). The fish consumption rate of 17.5 grams per day is considered representative of a central tendency value for recreational fishers, and 49 grams per day was selected as the reasonable maximum exposures value representing the higher-end consumption practices of recreational fishers. The consumption rate of 142 grams per day represents a reasonable maximum exposures value for high levels of fish consuming, or subsistence, fishers. The rates of 17.5 grams per day and 142 grams per day represent the 90<sup>th</sup> and 99<sup>th</sup> percentiles, respectively, of per capita consumption of uncooked freshwater/estuarine finfish and shellfish by individuals (consumers and non-consumers) 18 or older, as reported in the Continuing Survey of Food Intakes by Individuals (CSFII) and described in EPA’s Estimated Per Capita Fish Consumption in the United States (USEPA 2002). The consumption rate of 49 grams per day is from a creel study conducted in the Columbia Slough (Adolfson 1996), and represents the 95 percent upper confidence limit on the mean, where 50 percent of the mass of the total fish is consumed (Adolfson 1996). The above cited fish consumption rates are considered “conservative but within a realistic range of exposure scenarios” as recommended by the NCP. Further, as evidenced by public comments submitted by the six Tribes, they believe even the 142 grams per day consumption rate to be a low end exposure value for tribal consumption.

EPA disagrees with the contention that EPA’s evaluation was inconsistent with the NCP because EPA did not consider the likelihood of reasonable maximum exposures actually occurring consistent with the NCP preamble. As noted above, a consumption rate of 49 grams per day was used to evaluate risk on a river mile and SDU basis. This rate was based on a creel study conducted in the Columbia Slough and thus represents exposures that are “actually occurring” in the vicinity of the Site. Similarly, the consumption rate of 142 grams per day is lower than the fish consumption rate of 175 grams per day which was based on a study of fish consumption behaviors by tribal consumers in the Columbia River basin and was used by the State of Oregon to establish water quality standards for the protection of human health.

For the reasons cited above, EPA disagrees that the risk assessment information does not provide realistic information upon which to evaluate remedial alternatives and to base remedial decisions. Thus, EPA’s risk assessment fully satisfies NCP requirements.

EPA acknowledges that its risk assessment was based on a deterministic approach but notes that deterministic risk assessments are the prevalent approach for assessing risk to human health in accordance with EPA's risk assessment guidance and that the deterministic risk assessment approach was initiated by the PRPs.

EPA also disagrees that ecological risk was incorrectly evaluated. Risks to wildlife were evaluated on a river mile or SDU basis. This closely corresponds with key wildlife receptors at the Site such as mink and osprey. EPA believes that this is the appropriate scale over which to evaluate post construction risk to wildlife rather than on a site-wide basis.

EPA acknowledges that as described in the BHHRA, the exposure scenario includes a factor of 25 percent was used to account for the time spent fishing in a single area within the Study Area, which again may be a low-end estimate given that people living and fishing on river beaches, such as Willamette Cove. The 25 percent site-use factor was not used in the development of PRGs because the site-use factor applies to different areas within the Site as opposed to areas outside the Site.

The basis for not applying the site-use factor to the development of cleanup levels is described in the response to LWG Dispute Issue 1d (Appendix A of this document).

The commenters misstated the approach used to assess direct contact risk in the feasibility study report (USEPA 2016b). Cancer risks for RAO 1 were calculated using the rolling river mile concentrations averaged on a 0.5-mile scale and the sediment PRGs for each COC based on a  $1 \times 10^{-6}$  cancer risk. As noted in Appendix J of the feasibility study report, direct contact with sediment in the navigation channel segment was not evaluated for this RAO. In addition, the evaluation of direct contact human health risk presented in Appendix J only considered direct contact with sediment and did not consider beach exposures.

For further response on the assumptions on fish consumption see EPA response to LWG Dispute Issue 1r (Appendix A of this document).

#### **2.19.4 Risk Evaluation Is Inconsistent with Risk Assessment**

##### **Comment Summary**

Many commenters noted that the PRGs and evaluation of post construction risk presented in the feasibility study report were inconsistent with the procedures used in the baseline human health and ecological risk assessments. Post-construction risk evaluation assumes different exposure scenarios and spatial scales than the baseline risk assessments.

It was noted that EPA's post-construction risk estimates alter exposure scenarios and spatial scales and use inappropriate PRGs to inflate the perceived benefit of more aggressive actions. For example, For RAO 2, human health fish consumption risks, EPA generated post-construction SWACs for a range of spatial scales. However, in EPA-approved BHHRA (Kennedy/Jenks 2013), risks were evaluated by whole river miles with no longitudinal splitting. Similarly, for RAO 6, ecological bioaccumulation risks, feasibility study SWACs were generated on a rolling 1-river mile basis with longitudinal splitting and on an SDU scale. The PRGs for the various RAO 6 chemicals are based on different ecological receptors evaluated in the BERA (Windward 2013). Due differences in exposure parameters cannot be estimated by applying a "one size fits all" spatial scale to every PRG. Further, none of the BERA appropriate spatial scales are consistent with longitudinally split river miles or SDUs. Similarly, the DDE PRG is based on the BERA spotted sandpiper dietary assessment that was evaluated on a 2-river mile scale of beach sediment which differs from the feasibility study evaluation spatial scales

In addition, the risk reduction methodology presented in Appendix J glosses over many detail, thus it is not possible to fully comment on EPA's methodology. However, it is clear that many aspects were inconsistent with the baseline risk assessments. To accurately evaluate the alternatives, an accurate assessment of risk must be completed using the methods presented in the BHHRA and BERA.

It was also noted that the spatial techniques used to evaluate risk reduction in the feasibility study report are duplicative, confusing and overly complicated and do not accurately represent potential exposures. New methods were used to evaluate risk reduction and different data averaging methods and assumptions were used to develop SWACs. For example, site-wide post construction risk estimates were based on estimating a site-wide SWAC as 95 percent UCL of the SDU specific SWACs and then calculating risks based on an ingestion rate of 142 grams per day.

Finally, it was noted that the evaluation of risk reduction associated with bioaccumulation pathways in the feasibility study report assumed linearity in the food web model which is not accurate.

### **EPA Response**

EPA disagrees that the spatial scales evaluated in the feasibility study report (USEPA 2016b) are inconsistent with the baseline human health and ecological risk assessments. See the response to LSS Dispute Issue 9 (Appendix A of this document).

EPA has revised the applicable tables in the feasibility study report Appendix J. These are presented in the supplemental information for the ROD (Appendix IV).

## **2.19.5 Evaluation of Dioxins and Furans Is Inconsistent with Risk Assessment**

### **Comment Summary**

It was noted that the risk estimates and remedy development for dioxin furans was flawed because EPA did not assess dioxins/furans as 2,3,7,8-TCDD equivalents as was done in the BHHRA (Kennedy/Jenks 2013). This resulted in a significant disconnect between the BHHRA and post-construction risks for dioxins/furans for RAO 2. For example, for a breastfeeding infant, the highest HQ for dioxin/furan toxicity equivalence quotients calculated in the BHHRA are 10 on a site-wide basis (tribal fish consumption, whole body) and 10 on a river mile basis (recreational reasonable maximum exposure consumption). However, Table J2.3-1a indicates that the site-wide HQ for the same infant scenario is 785, almost two orders of magnitude higher. Similarly, for a child, the highest HQ for dioxin/furan toxicity equivalence quotients calculated in the BHHRA are 10 on a site-wide basis (tribal fish consumption, whole body) and 10 on a river mile basis (recreational reasonable maximum exposure consumption). However, Table J2.3-1a indicates that the site-wide HQ for the same scenario shows a site-wide HQ for HxCDF alone.

In addition, it was noted that EPA acknowledged the inadequacy of the HxCDF data in terms of quality and spatial coverage in the remedial investigation. Because EPA developed PRGs and RALS based on data characterized as inadequate, EPA abrogated its duty to produce scientifically sound and supportable risk estimates as well as cleanup criteria in the form of supportable PRGs and RALS. Finally, was noted that the approach for identifying which dioxin congeners to evaluate is unclear.

### **EPA Response**

EPA acknowledges that the evaluation of dioxins and furans in the feasibility study report (USEPA 2016b) differed from the evaluation in the BHHRA (Kennedy/Jenks 2013). However, the difference was fully explained in the feasibility study report in Appendix J. In the BHHRA, the risk associated with

exposure to dioxin and furans was evaluated as 2,3,7,8-TCDD equivalents (Dioxin toxicity equivalence quotients). However, it was not possible to develop risk-based PRG and background concentrations for dioxin toxicity equivalence quotients. Risk-based PRGs for dioxins and furan were calculated using the food web model which requires consideration of individual dioxin furan congeners with specific physiochemical properties. In addition, due to variations in the upstream composition of dioxin and furan congeners, developing background estimates for dioxin toxicity equivalence quotients was not considered technically valid.

The evaluation of risk reduction in the feasibility study report was conducted by estimating the post construction sediment concentration, estimating the fish tissue concentration through the food web model and estimating the residual risk based on a comparison to PRGs. As a result, the methodology is not directly comparable to the procedures used in the HHRA which estimated dioxin risk based on measured rather than modeled fish tissue concentrations. However, use of the food web model is required for the evaluation of post construction residual risk for Alternatives B, D, E, F, F Modified, G and I. It therefore appropriate to estimate the risk associated with the no action alternative, Alternative A, using the same methodology even though it does not provide the same results as the HHRA.

The approach for identifying the dioxin congeners that were selected for evaluation in the feasibility study is described in a December 23, 2014 memo from CDM Smith to EPA (AR Doc #10010497). The identification of the dioxin congeners for evaluation was based on identification of the dioxin congeners that pose the greatest risk to human health based on their concentration in smallmouth bass fish tissue collected during Round 3 of the Portland Harbor remedial investigation. Based on this evaluation, it was determined that 5 congeners contribute 85 percent of the risk (1,2,3,4,7,8-hexachlorodibenzofuran [HxCDF]; 1,2,3,7,8-pentachlorodibenzo-p-dioxin [PeCDD]; 2,3,4,7,8-pentachlorodibenzofuran [PeCDF]; 2,3,7,8-tetrachlorodibenzo-p-dioxin [TCDD] and 2,3,7,8-tetrachlorodibenzofuran [TCDF]. As described in Appendix D of the feasibility study report, the footprints for the 1,2,3,4,7,8-HxCDF and 2,3,7,8-TCDF RALs were determined to be covered by the footprints of the other three dioxin/furan congeners. Thus, the dioxin/furan congeners retained as focused COCs were 2,3,7,8-TCDD, 1,2,3,7,8-PeCDD, and 2,3,4,7,8-PeCDF.

### 2.19.6 Evaluation of Risk Should Consider Specific Factors

#### Comment Summary

It was further noted that risks vary according to site use and much of the Site is currently designated for industrial uses that provide limited or no access to recreational users. As a result, multiple PRGs should be established based on site-specific uses and conditions as done for the Lower Duwamish Waterway Site

The BHHRA (Kennedy/Jenks 2013) evaluated generic exposure scenarios used to evaluate risk to humans from contaminants. The only human exposure scenario driving EPA's proposed clean-up of PAHs at T4 is direct contact with sediment. Because there is no public beach access at T4, the only possible direct contact is from the water. In its most conservative fishing scenario, EPA assumed that a person would fish at Terminal 4 for 260 days per year for 70 years and during every single visit would cover his or her hands and forearms with sediment and ingest sediment when pulling up fishing lines or anchors.

EPA must adjust its Harbor-wide approach to direct contact human health risk and make risk management decisions based on site-specific considerations. Basing remedy selection on an assumption that direct contact with sediment is possible everywhere without consideration of variations in

conditions and land use leads to a T3 cleanup requirement that is unsupported by the facts and unrelated to real risk reduction.

It was noted that at the Terminal 4 site, current and future marine terminal make fishing (and beach access from fishing boats highly improbable. With extremely large ocean going vessels moving in and out every few days, navigation safety for fishing boats is an issue. In addition, the Port maintains a dedicated security operation and Facility Security Plan developed and implemented pursuant to Coast Guard regulations. As a result, fishing in the off-channel slips and bays at Terminal 4 consists of isolated *de minimis* instances and does not pose risk to human health. The Port noted that these site management and security protocols constitute governmental controls which EPA can recognize as existing ICs. The Port would be willing to discuss additional ICs with to ensure protectiveness that could be trigger upon future changes to site use.

One commenter stated that EPA continued to exclude use of a site-use factor for the evaluation of direct contact risk in the BHHRA. The commenter stated that use of a site-use factor of 25 percent would change the current RAO 1 PRG for carcinogenic PAHs measured as BaPEq from 106 to 424 µg/kg. The commenter further noted that not even alternative G meets the current BaPEq PRG for many half river miles but that if the site-use factor is accurately applied, a BaPEq PRG of 424 results and can be achieved by alternative A for all but a few half river mile areas.

### **EPA Response**

EPA disagrees that it did not consider Site specific factors when developing cleanup goals. For example, direct contact exposures were not assumed to occur within the navigation channel. Due to potential changes in future land and waterway uses, the recreational use of the river, and inappropriate reliance on ICs (security controls), EPA did not take into account shipping and security controls during the evaluation of risk or in the development of remedial action alternatives. It should be noted that while the Portland Harbor Site is designated for industrial uses, it also serves as a resource for recreational and subsistence fishing. Regarding the development of location specific remedial cleanup levels as was done for the Lower Duwamish Waterway Site, EPA notes that location specific PRGs have been developed for PAHs. For example, PRGs for RAO 2 apply throughout the Site while PRGs for RAO 1 only apply to nearshore areas.

## **2.19.7 Alternative I Fails to Meet Several Superfund Criteria**

### **Comment Summary**

One commenter stated that EPA's selected remedy did not meet certain evaluation criteria. Specifically:

- Criteria 1 (overall protection of human health and the environment. Alternative I's failure to meet Threshold Evaluation Criteria 1 (overall protection of the human environment), should have been cause for eliminating Alternative I right from the start.
- Criteria 3 and 5: Based on its failure to meet Balancing Evaluation Criteria 3 (Long-term Effectiveness) and Criteria 5 (Short-term Effectiveness) EPA should have shifted to a more aggressive alternative.
- Criteria 9: Based on the failure to meet Modifying Evaluation Criteria 9 (Public Acceptance), EPA should take a hard look at why after 16 years EPA has failed so profoundly to meet the needs of our community and take the time necessary to select a remedy that will meet our community's needs and the requirements of the law.

### EPA Response

EPA disagrees that EPA's selected remedy did not meet the NCP evaluation criteria. Through active remediation, natural recovery and ICs, EPA's selected remedy is considered protective. To increase the confidence in the remedy's ability to meet the threshold criterion of (overall protection of human health and the environment, EPA has selected Alternative F with modifications in the ROD.

EPA also disagrees that it did not fully consider the balancing criteria of Long-term Effectiveness and Short-term Effectiveness. As described in Section 4.1.5 of the feasibility study report (USEPA 2016b), the evaluation of long-term effectiveness and permanence considered the magnitude of residual risk based on each of the RAOs and the adequacy and reliability of ICs. Similarly, the evaluation of short-term effectiveness considered the time needed to implement the remedy and any adverse impacts that may be posed to the community, workers, and the environment

Finally, EPA disagrees that its remedy does not consider the public acceptance. As noted in the ROD, EPA held numerous outreach events and extended the public comment period by 30 days. As noted elsewhere, EPA believes that its proposed remedy fully complies with the requirements specified in CERCLA and the NCP.

### 2.19.8 Address Miscellaneous Risk Issues

#### Comment Summary

Several other comments relating to risk were received, and are summarized below:

- Post construction risks are only estimated for post construction conditions and not any other timeframe. Because of the reliance on MNR, the lack of a post-construction risk estimate process for time intervals post construction makes the usefulness of the post construction risk estimates limited.
- Risk reduction was not accurately presented. The combination of the use of zero as replacement values and the lack of incorporation of estimates of MNR/ENR in any of the remedies overestimates risks from remedies that include more capping and MNR/ENR and under estimates risk for removal technologies due to the generation of residuals.
- Some of the risk-based PRGs reported by EPA are much less than background estimates either as calculated by EPA or LWG and that because these PRGs are unachievable, the post construction risk estimates are meaningless.
- Due to the contribution of COCs from upstream due to background conditions, the target risk range should have been set between  $1 \times 10^{-4}$  and  $1 \times 10^{-5}$ .
- The feasibility study and proposed plan did not consider upstream fish tissue concentrations – either measured or predicted – relative to site concentrations to assist in the development of cleanup levels
- The fish meals/10 years was not used in the BHHRA (Kennedy/Jenks 2013) and no basis was provided for this new unit and some tables presented in Appendix J are include cPAHs and some do not.
- EPA assigned a shellfish consumption PRG to the navigation channel even though no shellfish harvesting can occur in the navigation channel.

- Several commenters noted that the risk associated with background levels of mercury was not considered. The risks associated with mercury in fish tissue and the background (based on up-river conditions) and equilibrium-based concentrations of PCBs (based on ongoing loads from the urban watershed) should be stated as a practical limit on the future remediation activity's ability to materially change the fish consumption risks for those who eat fish from the Site.
- A fisher survey should be conducted to gather information on the number of persons actually fishing in the Lower Willamette River and their type and frequency of fishing activities.
- A probabilistic risk framework is appropriate for this complex Site and would provide an assessment of who is or is not at risk from consumption of fish or other exposures at the Site. ExxonMobil prepared a probabilistic risk assessment to provide information on realistic risks at the Site and risk reduction that could be achieved by the remedial alternatives being considered by EPA.
- Residual risk estimates were presented in Appendix J of the feasibility study report. Several commenters noted errors in the calculations and that the calculations could not be reproduced. For example, it was noted that some of the tables in Appendix J include arsenic, aldrin, chlordanes, and dieldrin and the dioxin/furan congeners 2,3,7,8-TCOF, 2,3,4,7,8-PeCOF, and 1,2,3,4,7,8-HxCDD in addition to PCBs, ODx, and 2,3,7,8-TCDD. While others are missing cPAHs (such as Table J2.3-1a).

### **EPA Response**

Regarding the development of post construction risk estimates that consider MNR, EPA disagrees with the assertion that the feasibility study report lacked a process for considering risk reduction post-construction. The decision documents clearly state that multiple lines of evidence indicate that natural recovery of contaminant concentrations is occurring and is anticipated to occur in the future, particularly following upland source control and active remediation of the most-heavily contaminated portions of the sediment bed. That projected recovery is the fundamental premise for slating large areas of low level contamination for natural recovery instead of active remediation. However, EPA does not believe that quantitative predictions from models that cannot reasonably be expected to be quantitatively accurate should be relied upon for decision making. Indeed, reliance on such analyses is potentially misleading, especially in highly dynamic and heterogeneous environments that do not lend themselves to long-term quantitative predictions. In lieu of a reliance on model output, the post-construction timeframe includes monitoring to measure the extent of natural recovery and attainment of remedial cleanup levels and RAOs. If progress or attainment of goals is not sufficient, additional remediation will occur based on outcomes of the five-year review process. Overall, EPA determined that evaluating alternatives based on estimated post construction concentrations without incorporating quantitative, but inaccurate, natural recovery predictions was more appropriate for remedial decision making. Post construction sediment concentrations were assumed to be zero in active remediation areas because active remediation incorporates clean material in residual management layers, backfill, and caps, so the use of zero as a replacement value was considered appropriate.

The fact that risk-based PRGs are below background is irrelevant because risk-based thresholds below background were not selected as PRGs; rather the background concentration was utilized. However, when estimating residual risk, EPA compared post-construction sediment concentrations to risk-based PRGs as described in Appendix J rather than running the post-construction sediment concentrations through the food web model. While this imparts a certain amount of uncertainty for bioaccumulation

pathways (RAOs 2 and 6) due to the non-linearity of the food web model, this approach is considered appropriate for a feasibility study level evaluation.

It was noted that due to the contribution of COCs from upstream due to background conditions, the target risk range should have been set between  $1 \times 10^{-4}$  and  $1 \times 10^{-5}$ . EPA notes that in many instances, the resulting residual risk estimate presented in Appendix J falls within this range (See Table J2.3-3f).

Regarding the use of upstream fish tissue concentrations to assist in the development of cleanup levels, because the focus is remediation sediments, background based PRGs were developed only for sediment.

Regarding the use of fish meals per 10 years as a metric for evaluating risk reduction in the feasibility study, please see the response to LSS Dispute Issue 8 (Appendix A of this document).

Regarding the evaluation of the risk associated with shellfish consumption in the navigation channel, there is no information to suggest that shellfish harvesting *cannot* occur in the navigation channel.

EPA acknowledges that background levels of mercury within the Willamette watershed may exceed acceptable levels. However, that does not obviate the need to address the risks associated with releases of hazardous substances at Portland Harbor such as but not limited to: PCBs, dioxins and furans, DDx and PAHs. Comments stated that background levels of mercury may continue to pose risk due to up-river sources that should be evaluated. Consistent with EPA's background policy, the risk assessment evaluated risks associated with mercury and addressed site-specific background issues in the risk characterization. As noted in the background policy, cleanup levels are not set at concentrations below natural background levels under CERCLA.

Several comments stated that a fisher survey should be conducted to gather information on the number of persons actually fishing in the Lower Willamette River and their type and frequency of fishing activities, EPA notes that a creel survey based on Columbia Slough fishers was used to establish the reasonable maximum exposure fish consumption rate for recreational fishers.

Several commenters have noted errors in the residual risk estimates provided in Appendix J. However, without additional information, it is not possible to determine whether the errors are actual or not.

### 2.19.9 Address Seismic Issues

#### Comment Summary

Twenty-seven comments were received that cited earthquakes as a major concern related to EPA's preferred alternative. Almost all were individual, personal comments. Some comments said that the remedy did not meet the criteria for long-term effectiveness and permanence. The general focus was mainly on contaminants being released to the river in times of crisis. The sources of that contamination were varied and included capped and uncapped river bottom sediments, upland soils, the CDF, and tank farms (not associated with the remedy). Cooperation in planning was also requested as were tsunamis.

Representative comments include:

- "The Proposed Alternative I does not meet the criteria for long-term effectiveness. Burying contaminants in the river bottom has short-term benefits, but it leaves open the risk that any major event, earthquake, flood, or even a ship turning the wrong way, will disturb the cover material and release the contaminants back into the river system. "

- “As EPA well knows, the Pacific Northwest is overdue for a massive earthquake. This will provide ample opportunity for the debris on the bottom of the river to migrate, and, if EPA is short-sighted enough to cap the toxic debris within the river itself and then assume the cap will withstand the earthquake without breaking free and recontaminating the river, I believe you are sorely wrong. “
- “The Cleanup Plan makes no mention of the fact that a subduction zone earthquake will occur and effects to the Portland area will be great. We don't know the timing of this event, so any cleanup should address the issue. This region will have plenty of issues to deal with after the quake, we don't need to worry about recontamination of the river with sludge from a confined disposal facility. Any upland disposal site chosen should also be protected from remobilization of the sludge during an earthquake. “
- “My primary concern about the in-river disposal facility is the lack of seismic protection. If the Cascadia earthquake hits a non-seismically protected disposal facility full of contaminated sediment, it will be right back in the river. At that point, why did we even spend money on it in the first place? I recognize the limitations to shipping it off site - the trucks from Portland Harbor would be going right by my house. However, where ever we put the sediment, it needs to be protected from the largest possible earthquake we are expecting from the Cascadia subduction zone. Despite the large amount of other contaminants that are going to be dumped in the river during a large earthquake (namely gas fields, industrial waste held shore-side, etc. etc.), to meet EPA requirements of developing the executing the most cost-effective project, we need to make sure that contaminated sediment, wherever it is located, is seismically protected in the case of a worst-case-scenario earthquake. “
- “Please allow me to emphasize particular points:
  - I am concerned about the impact of the anticipated tsunami earthquake which will in all probability, occur during cleanup and restoration of the Superfund site at least somewhere on the river. Has this been adequately addressed?
  - The consequences of disturbed pools of pollution and toxins. What about the instability and certainty of liquefactions of soils bearing the Northwest tank farm? In my opinion this area in anticipation of the quake should be stabilized (if possible) or the tank relocated as part of superfund operations or at least in conjunction with the latter. “
- “There is no mention of the risk of seismic activity or significant flooding that would stir up the river bed. No one knows what a massive earthquake would actually do, but we know the risk of a deep subduction earthquake within the next 50 years is estimated to be about 50 percent. All that contaminated sediment could be stirred up and added to the mix of other toxins that would add significant danger to recovery efforts after a quake. “
- “The City request that EPA work with the Federal Emergency Management Agency, the City, and other local government agencies to include all appropriate measures in the ROD and RD/RA to address recontamination risks associated with a catastrophic earthquake. In addition to remedy selection, design and action, the City request that the fuel tank farms within the Site be evaluated as a potential source of recontamination in the event of an earthquake. After we have invested

hundreds of millions of dollars in this cleanup, we want to make sure that we do everything in our power to keep it clean.”

- “Many of these tanks are very old, and are in dire need of updating, and/or replacement. It has been well-documented that the soils on the west side of the river consist largely of fill material, and that these soils would liquefy with a significant earthquake event. We urge the US EPA to include language that identifies the issue, and makes a commitment to work on it outside of the Superfund process. EPA has an opportunity to assist the State of Oregon, the City of Portland and others to develop an action plan to reduce the risk to the river from these tanks from a significant earthquake event.”

### **EPA Response**

For areas to be capped, the feasibility study considered sediment bed slope as a factor in determining the favorability of this technology, which is an indirect consideration of seismic stability. The feasibility study assumes that capping on slopes less than 15 percent does not require special considerations. Slopes of 15 to 30 percent require special considerations that warrant a more engineered design and will be given further consideration of key details during design, such as geotechnical data to be collected, which may restrict capping areas or otherwise change the design in the context of an earthquake. Caps were not considered on slopes greater than 30 percent. For those areas carried forward in the ROD for capping, impacts from large earthquakes will also be considered in remedial design, including distance from active faults, maximum expected earthquake magnitude, probability of occurrence, physical properties of sediment and capping material, and slope. Slope stability on remediated river banks will also be a consideration during remedial design to ensure engineered caps are placed in a fashion that is protective of human health and the environment considers earthquake risk and extreme weather events.

In regards to the upriver tank farms, the Superfund program addresses spills which have already occurred and are uncontrolled releases into the environment. Releases from fuel farms and other petroleum storage facilities is regulated under Spill Prevention, Control, and Countermeasures and other regulations, which take into account threats such as earthquakes. EPA has previously and will continue to evaluate the potential of remedy recontamination from historical uncontrolled releases into the environment, but that does not include the potential future release of hazardous substances stored at or near Portland Harbor. EPA will work with local municipalities in ensuring that earthquake contingencies for the CERCLA remedy are part of the ICs implementation and assurance plan to be developed after the ROD.

## **2.19.10 Design for Climate Change**

### **Comment Summary**

Many comments very briefly referenced climate change as part of larger comments such as CDFs, upland sources, or the need to move quickly.

Three comments specifically addressed the need to account for climate change in designing the remedy:

- The proposed plan does not appear to consider long-term changes in climate, changes in river level, increased salinity, frequent storms, scouring, or the potential for flooding upland areas. It does not consider the potential impacts of catastrophic climate change.
- “The proposed plan does not account for the potential risks associated with climate change as required in Executive Order 13653 (November 1, 2013). Specifically, the feasibility study fails to

account for the potential for increasing frequency of floods due to climate change, including climate impacts from the Columbia River in the Portland Harbor study area, which are different and temporally offset from the impacts in the Willamette River itself. EPA's Climate Change Adaptation Technical Fact Sheet provides specific steps for addressing climate change for contaminated sediment remedies, including evaluation of vulnerabilities and identification of adaptation measures to provide additional resiliency<sup>15</sup>. Additional Site-specific scientific studies are also available. The City requests that EPA update its climate change evaluation to be more accurate and to develop a climate change adaptation plan for the cleanup."

- "EPA should account for the potential impacts of climate change on the efficacy of the remedy. It is unclear whether EPA has adequately accounted for the potential impacts of climate change on the efficacy of their proposed alternative or on the other alternatives that were considered. This is required under Executive Order 13653.<sup>15</sup> The impacts of climate change are likely to have a profound impact on the Willamette River during the life of EPA's cleanup plan, all the more so given that it is far from certain when the cleanup goals will actually be achieved. This is likely to include increased flood events in terms of both frequency and volume. This could have profound implications for the efficacy of the remedy across the uplands, river banks and inwater environments. EPA should consult its own Climate Change Adaptation Technical Fact Sheet as well as other tools that it has developed to incorporate the impacts of climate change into its Superfund Program (<https://www.epa.gov/superfund/superfund-climate-change-adaptation>)."

### **EPA Response**

As described in Section 3.4.4 of the feasibility study report (USEPA 2016b), EPA considered climate change impacts on river flows in the Willamette watershed. Climate change is anticipated to result in an increase in winter flow and a decrease in summer flow, with an earlier peak flow. More high flow events are expected but of less magnitude than the large historical flood events. An assessment of the potential effects of increased river flows will be conducted during remedial design.

## **2.19.11 Manage Flood Rise**

### **Comment Summary**

Two comments were received that related to management of flood rise as part of the cleanup. The City of Portland provided a comment regarding EPA's plan to ensure that flood rise management complies with regulatory requirements throughout the Site. The City points out that it qualifies for federally-backed flood insurance and federal disaster assistance because it follows the floodplain standards of the National Flood Insurance Program. The City comment requests that EPA ensure that remedy selection and design adequately consider flood management and not impair the City's ability to maintain its qualification for its favorable status under the National Flood Insurance Program. As part of the flood rise management evaluation, the City requests that EPA use its definition of "no rise" to mean less than 0.005 feet of rise, such that the rise would be equal to 0.00 feet when rounded and reported to the hundredth of a foot. The comment states that the U.S. Federal Emergency Management Agency has concurred with this definition. The City points out that cut and fill amounts and location may change during remedial design based on Site-specific factors. Additionally, remedies are likely to be sequenced over several years in different areas of the river, with the potential to cause temporary flood rises. Hence, the City would like the ROD to describe how the evaluation (using the HEC-RAS model computer program) will be revised during individual project phases to assure that there are no cumulative effects of flood rise. The Audubon Society also provided a comment questioning whether the plan allows the

City to retain adequate flexibility to mitigate for future floodplain impacts in the North Reach of the Willamette unrelated to Superfund.

### **EPA Response**

The Portland Harbor cleanup must comply with floodplain management executive orders and Federal Emergency Management Agency standards to not adversely affect floodplain capacity, which is a “no rise” standard. Executive Order 11988 on Floodplain Management requires federal agencies to document that actions they authorize in floodplains will not adversely affect floodplain capacity or cause floods to encroach upon new areas by increasing base flood elevations. During remedial design a floodplain impact study analyzing the effects of the selected remedy on flood characteristics, specifically base flood elevations, of the lower Willamette. This study will encompass the areas proposed for active remediation as well as adjacent upstream and downstream reaches that could potentially experience flood impacts resulting from the remedy selected in the ROD.

An assessment of impacts from the remedy will be conducted on identified Flood Hazard Areas. These analyses will provide documentation demonstrating that the cumulative effect of the remedy, when combined with all other existing and anticipated work, will not increase the water surface elevation of the base flood more than 1 foot at any point within the regulatory flood hazard area, and no rise (0.00-foot) in the base flood elevation within the defined regulatory floodway. These analyses will be certified by a professional engineer licensed in the State of Oregon.

An analysis was performed during the feasibility study and summarized in Appendix P of the feasibility study report (USEPA 2016b) comparing estimated volumes of capping and dredging for the various alternatives within each SDU as well as site-wide. Evaluated on a Site-wide scale, the volume of fill for each alternative is expected to be generally less than the total volume removed, resulting in a net cut volume. Evaluated on a SDU basis, the volume of fill for each alternative is less than the total volume removed for most the SDUs. EPA acknowledges that this analysis is not the final analysis to meet the requirements of Executive Order 11988 and a more detailed analysis will be required during remedial design based on regulatory, existing and proposed site-specific factors.

A comment was also received from the Audubon Society inquiring whether the plan allows the City to retain adequate flexibility to mitigate for future floodplain impacts in the North Reach of the Willamette unrelated to Superfund. The comment is not clear as to what kind of mitigation is being referred to (flood mitigation or ecological/habitat mitigation). Assuming the question is will the remedy affect the ability to implement habitat mitigation that could be required by industrial development in the floodplain to address possible adverse impacts to wetlands, riparian woodland and/or avian habitat then the answer is no, if the mitigation is not planned for areas identified for remediation. Any habitat mitigation planned for regulatory floodplain/floodway areas of the Willamette River fall under the same regulations as the Portland Harbor remedy ARARs (Executive Order 11988) and would require local floodplain permitting. EPA believes there is no reason why either flood or habitat mitigation would be restricted by the remedy as any restriction would be regulation-based.

## **2.20 Short-term Effectiveness**

### **2.20.1 Address Inadequate Evaluation of Short-Term Effectiveness**

#### **Comment Summary**

Comments on short-term effectiveness were received from the multiple businesses, Portland Audubon Society, the Portland Water Conservation District, West Multnomah Soil and Water Conservation District, and Associated Oregon Industries. The comments expressed concerns that the short-term

effectiveness evaluation was inadequate due to lack of quantitative analysis, detail and/or missing components such as logistics. Commenters requested additional analysis of several short-term impacts per NCP guidance. LWG called short-term impact mitigation measures biased and dismissive of short-term impacts, and commented that these measures misleadingly suggested short-term impacts are inconsequential. TMG and BAE commented, "... [the] proposed plan's brief discussion of remedy effectiveness and implementability provides no substantive explanations for its comparison between remedial alternatives, instead stating broadly that *'the potential for technical problems and schedule delays increases in direct proportion to the duration, amount of active remedy.'* [Id., p. 57]" ARCO and BP West Coast Products commented that short-term impacts increase proportionately as the remediation footprint decreases.

Commenters did not feel that the risk associated with disturbance of sediment during dredging and capping was well addressed:

- The PCI Group commented that EPA did not consider that larger footprint remedies cause greater suspension of contamination and disruption to Portland communities.
- West Multnomah Soil & Water Conservation District asked if "there is risk of increased toxicity of contaminants due to removal from the river, or risk of atmospheric exposure to contaminants[,] ... how EPA plans to mitigate this risk," and how this was considered in Alternative I selection as preferred.
- The Marine Group and BAE Systems expressed concerns that it is unclear if Portland can accommodate 200 truckloads of material and waste per day and how their estimated 1 barge/day at Swan Island SDU can be accomplished in a narrow lagoon used as part of an active industrial harbor.
- The Portland Audubon Society requested robust implementation of Implement air, water and fish tissue monitoring during construction, while Portland General Electric suggested that due to the lack of in-depth analysis, "It is conceivable that the cleanup activities have the potential to produce more adverse risks and injuries than the risks posed by the current condition of the river."

Commenters pointed to many short-term impacts that they did not feel were adequately addressed in the ROD including:

- Occupational and implementation related injuries, disease, and deaths caused by the cleanup activities
- Potential for accidents during construction
- Community impacts from construction activities and increased traffic (water, road and rail)
- Business disruption
- Negative net economic impact
- Noise, air, and light impacts
- Recreation disruption

- Greenhouse gas and air pollution discharges
- Release of contaminants during dredging
- Fish advisories during construction

To address noise, air, light and other quality of life issues, Olympic Tug and Barge recommended using the *Environmental, Economic, and Social Analysis Reports* prepared by AECOM, NERA, and SEA Environmental Decisions, Ltd. on behalf of the Portland Harbor Superfund Site Sustainability Project for submittal to U.S. EPA in September 2016 (Portland Harbor Sustainability Project 2016).

Some commenters were more concerned with short-term risks, and requested consideration of alternative B or another option that minimized short-term impacts. Others felt that long-term effectiveness should have more influence in alternative selection than short-term effectiveness, and requested EPA select a more aggressive option than alternative I because it appears to prioritize short-term effectiveness over long-term effectiveness. Union Pacific asked EPA to explain "... how the preferred alternative's combination of active remediation and monitored natural recovery achieves cleanup goals in a substantially shorter time than less aggressive alternatives using a different combination ...". LWG questioned why Alternative B received a lower score than alternatives with longer and more extensive construction, and questioned why none of the alternatives were classified as "best" for short-term effectiveness.

### **EPA Response**

EPA's two threshold criteria for selection of a Superfund remedy are protection of human health and the environment and compliance with the substantive requirements of federal and state environmental laws. Short-term effectiveness is one of five balancing criteria, which EPA used to perform the detailed analysis of alternatives.

EPA short-term effectiveness analysis was conducted in accordance with NCP. 40 CFR §300.430(e)(9)(iii)(E), which states:

*The short-term impacts of alternatives shall be assessed considering the following:*

1. *Short-term risks that might be posed to the community during implementation of an alternative;*
2. *Potential impacts on workers during remedial action and the effectiveness and reliability of protective measures;*
3. *Potential environmental impacts of the remedial action and the effectiveness and reliability of mitigative measures during implementation; and*
4. *Time until protection is achieved.*

In addition to the short-term effectiveness evaluation in Section 4.2 of the feasibility study report (USEPA 2016b), potential impacts on various human uses of the Site, including recreational, commercial and subsistence fisheries, water-related recreation, aesthetics, riverside parks, and other uses were evaluated in Appendix L of the feasibility study report, in compliance with Section 404 of the Clean Water Act. EPA disagrees that the feasibility study analysis does not allow for meaningful comparison amount alternatives, including consideration of proportional differences in short-term impacts.

Additional evaluation of short-term impacts and mitigation measures will be ongoing throughout remedial design and construction planning while specific technologies and schedules are planned for each area of the Site. See also responses to Union Pacific Railroad Dispute Issue 5, RALs, Transparency, Sustainability, Dredging, Economic Impacts, MNR, and Sheet Piles comments for additional information regarding short-term impacts. Fish advisories during construction will be established as discussed in responses to ICs.

Per the NCP as stated above, EPA must consider not only short-term impacts, but mitigation measures and effectiveness of those measures as well. A summary of the evaluation of these factors is provided in Sections 4.2.2.5 and 4.3.5 of the feasibility study report. While the implementation of the remedy is likely to present various short-term construction-related impacts to the Portland Harbor community due to potential increased road, train and river traffic, noise, and other construction related activities, these impacts will be mitigated to the extent practicable. For example, EPA is recommending the use of barges as the primary means of transport coupled with use of off-site transload facilities to minimize impacts on the community. Section 4.2.2.5 of the feasibility study report outlines the mitigation measures and best management practices that will be implemented to protect the community, workers, and the environment during construction of the remedial action.

EPA is committed to working with the community to minimize short-term impacts, including any temporary disruptions to public amenities. In addition, EPA requires site-specific and activity-specific health and safety plans be implemented by the parties performing the cleanup, so that the cleanup is conducted in a safe manner. EPA has conducted extensive community outreach during the development of the remedial investigation, feasibility study, and proposed plan (USEPA 2016c) and is committed to maintaining a transparent, proactive community interaction process during each cleanup phase and on all key elements of the design and implementation. For more information regarding monitoring and mitigation of construction-related impacts, see Sections 2.2.9, 2.17.3, and 2.17.4 of this responsiveness summary.

EPA also acknowledges that enhanced fish consumption advisories will be needed during implementation to address the potential for fish to be exposed to contaminants and subsequently increase human health risk of eating those fish. For more information on fish consumption advisories, see Sections 2.3.2 and 2.28.2 of this responsiveness summary.

EPA acknowledges that Table 4.3-3 of the feasibility study report contained an error which designated Alternative B short-term effectiveness as “Moderate” instead of “Best.” However, Alternative B does not meet the threshold criteria and was therefore not a viable alternative.

EPA did not prioritize the minimization of short-term risks over the minimization of long-term risks. Per EPA guidance, short and long-term risks were not looked at as tradeoffs, but rather as part of a holistic view of alternative evaluation. While Alternative G may have the most reduced long-term risks, the feasibility study report selected Alternative I in part due to its superior ability to minimize short-term disruption and risks. The selected alternative in the ROD, Alternative F Modified reduces long-term human health risks more quickly than Alternative I and minimizes reliance on ICs and likewise minimizes short-term disruption and risks over Alternative G. See Sections 2.1.1 and 2.31.1 of this responsiveness summary for additional information on alternative evaluation and selection.

## 2.20.2 Consider Externalities in Designing a Remedy

### Comment Summary

Two comments were received that requested a remedy that provides greater overall benefits to the community. One commenter stated that although EPA's mandate under CERCLA required a focus on reducing health risks of contaminant exposure, an interest in "broader public health benefits" should be factored into the cleanup decision, such as how the project design should address the impact of the expanded truck and barge traffic via diesel emissions and improving access to greenspaces to promote better health. They requested more clarity in interim benchmarks - how they were generated, how can they be implemented, and what flexibility might there be for strategies that hit the performance measures of improved habitat and lower cancer and overall health impact. One person believed that the alternative evaluation process should take into account potential costs to human and environmental health from the "full effects of living next to a river full of PCB's."

### EPA Response

The Superfund law, CERCLA, sets out EPA's authorities for responding to releases of hazardous substances and pollutants or contaminants into the environment and established requirements that all CERCLA remedies must meet. CERCLA's implementing regulations, the NCP, provides the framework used to investigate releases, evaluate the risks posed by the releases, evaluate cleanup alternatives, and select a final remedy - among other things. Most relevant to the commenters concerns, the NCP, established nine evaluation criteria that puts the statute's mandates in a decision-making framework for assessing individual alternatives and performing a comparative analysis that focuses upon the relative performance of each alternative against those criteria. The overarching goal of the CERCLA response is to ensure protectiveness of human health and the environment. Protectiveness is one of the two threshold criteria for remedy alternative evaluation. Consideration of public health benefits and overall improvement in the community is for the most part outside the scope of a CERCLA response. EPA may implement remedies that minimize the environmental footprint of a remedy such or take into consideration land use consideration in the implementation of the remedy.

Another remedial alternative evaluation criterion is short-term effectiveness. Key factors considered during the evaluation of short-term effectiveness include protection of the community and workers and minimizing environmental impacts during remedial actions. Consistent with national and regional Green Remediation guidance, EPA's remedy can factor in mitigating activities to limit the overall environmental footprint of the response.

EPA has taken into consideration many of the short-term impacts commenter expressed to the extent that they are within the scope of the CERCLA law. EPA will limit impacts to the community from performance of the cleanup itself by using barges rather than trucks or rail to transport contaminated sediments for disposal. The response will minimize volatile emissions and odors from excavation using activities such as pollution control devices during construction activities routing trucks in a manner that avoids schools, or upgrades to road facilities to increase safety in the context of increased truck traffic in remedial design. Best management practices to reduce short-term impacts will be further considered to reduce emissions include, but are not limited to:

- Use of reusable energy sources.
- Limit idling of trucks and equipment.
- Rely on local sources of materials.

- Ensuring that trucks, barges and railcars are full prior to transport.
- Implement on-site dust and noise control to reduce air pollutant and greenhouse gas emissions.
- Require clean fuel and emissions control retrofit incentives in construction contracts.

Measures will be developed during the design process to reduce impacts of habitat as part of the cleanup and there will be a need for compensatory mitigation where loss occurs. EPA's authority under CERCLA however is limited to remedial actions designed to address releases of hazardous substances or pollutants and contaminants. While some of the nine evaluation criteria involve considerations of overall protection of human health and the environment, long- and short-term impacts, the focus of cleanups are reducing or eliminating exposure to the hazardous substances or pollutants and contaminants.

Some considerations requested by the commenters are outside the scope of EPA's authority. For example, consideration of diesel emissions from Interstate 5, health care costs, and increasing access to greenspaces. However, by reducing contaminant levels in surface water and sediment, EPA expects to increase the opportunity healthy recreational opportunities (such as boating, swimming, and fishing) in the Lower Willamette River thus contributing to the overall health of the community.

### 2.20.3 Explain Preference for Alternative I in Terms of Increased Fish Meals

#### Comment Summary

One comment was received that stated:

- "EPA's preferred Alternative I will restrict fish meals for most populations to a rate of no more than 6 fish meals every 10 years throughout the construction period. (Plan, pp. 58 - 59.) After construction, Alternative I achieves 50 fish meals every 10 years. EPA advocates this result without explaining how 5 fish meals per year addresses the nutritional requirements or recreational concerns of either tribal or recreational fishers. There is no obvious reason to prefer Alternative I (7 years of 0.6 fish meals to achieve 5 fish meals per year) to Alternative B (4 years at 0.6 to achieve 3 per year) or, for that matter, to Alternative G (19 years at 0.6 to achieve 10 per year). EPA's preference seems wholly arbitrary."

#### EPA Response

The number of acceptable fish meals per unit of time represents nothing more than a calculation of post-construction or residual risk, based on predicted tissue concentrations using the food web models developed and used by LWG. Consistent with the assumptions used in the BHHRA (Kennedy/Jenks 2013), post-construction fish consumption risks on a river-mile scale were evaluated using PRGs calculated based on a consumption rate of 49 grams per day. Within the Site, persistent contaminants (particularly PCBs, chlorinated pesticides such as DDT, and polychlorinated dioxin and furans) from sediments and surface water bioaccumulate in the food chain, resulting in higher concentrations of the contaminants in fish tissue than in sediments. Existing Oregon Health Authority fish consumption advisories apply to all resident fish at the Site, including carp, bass, and catfish, advising none of these fish be consumed by children under age 6, women of childbearing age, and people with thyroid or immune system problems and no more than 1 fish meal per month for everyone else. These resident fish, in contrast to migratory salmon, are the main contributors to human health risk associated with consumption of fish from the Site. Fish advisories once cleanup has achieved its goals, though less restrictive in the future, may need to remain due to broader watershed issues.

## 2.21 Implementability

### 2.21.1 Consider Geotechnical Issues in Dredging Adjacent to Improved Shorelines

#### Comment Summary

One commenter said that although the proposed plan states that "where SMAs are projected onto the river bank, removal followed by capping is the assigned remedial technology," EPA has failed to consider the technical and regulatory difficulties that would be associated with dredging adjacent to such banks and associated over-water structures, or the actual costs that would be associated with implementing that portion of Alternative I. Due to the river-dependent uses of river frontage properties, banks are typically over steepened beyond the angle of repose associated with the native soils and sediments, and the angle is maintained by the presence of extensive arrays of piling, rip rap or bulkhead and overwater structures throughout the Site.

#### EPA Response

During remedial design, geotechnical issues related to area-specific features will be evaluated. The decision tree in the ROD has been revised to clearly outline this process. Also, EPA agrees that maintaining flexibility in construction methods through the remedial design phase is an important consideration, particularly for nearshore areas near structures and area with debris.

Dredging adjacent to river banks and associated over-water structures require special considerations that warrant a more engineered design and will be given further consideration of key details during design, such as geotechnical data to be collected, which may restrict dredging/capping areas or otherwise change the area-specific design.

Cost associated with these issues are captured under bid contingency, which accounts for changes that occur after the construction contract is awarded. Examples include technological, geotechnical, and other unknowns applicable to the construction phase.

### 2.21.2 Be Flexible in Technology Selection and Implementation

#### Comment Summary

Three comments were received that expressed the concern that EPA's proposal to remove sediments adjacent to critical structures and utilities could potentially jeopardize the integrity of these structures. Comments stated that the docks and other in-river structures are vital to trade and commerce and their removal would cause severe negative consequences for some commercial operations along the Site.

Commenters believed that EPA should retain sufficient flexibility to allow for evaluation of emerging technologies, including in-situ options, for areas such as RM 11E. The ROD should provide flexibility in making technology assignments beyond the limited decision tree options identified in the proposed plan where site-specific conditions so require.

#### EPA Response

EPA appreciates the concern expressed by commenters related to ensuring that critical structures and utilities are not jeopardized. EPA used several lines of evidence based on conditions described in the remedial investigation report to determine the appropriate technology to apply to various areas of the Site. Particular information developed during the remedial investigation regarding river bottom, depth, or other physical condition and river use was applied in selecting technologies to evaluate in the feasibility study. The 2016 feasibility study report (USEPA 2016b) applied information about currently

known conditions to develop remedial alternatives that can be compared to each other to inform remedy selection. Example technologies were evaluated for cost estimating purposes only. Updated information about river conditions and land or river use will be obtained during remedial design in order to determine appropriate technologies to apply. Details regarding the use of sheet piling will be determined during remedial design which is the appropriate time for those types of evaluations.

EPA agrees that maintaining flexibility in type of construction methods through the remedial design phase is an important consideration. The ROD includes a flexible decision tree along with general design requirements to guide the assignment of capping and dredging technologies, based on specific characteristics within SMAs. The decision tree will be used during remedial design to define what actions should be taken under different environmental conditions and locations based on the most recent design data. Once the data and river factors are evaluated within the context of the decision tree, a final design for construction can be completed. This design will then dictate the remedial construction. The decision tree is intended to provide clear direction on what actions should be taken under the different environmental conditions.

### 2.21.3 Explain Design Considerations Near and Adjacent to Navigation Channel

#### Comment Summary

The USACE and the City of Portland expressed concerns about the design considerations considered for the use of beach mix backfill and capping near and adjacent to the navigational channel. It was stated that, as parts of the river are erosional, measures should be required to ensure that the beach mix will stay in place. It was requested that EPA explain design considerations to account for and counter any erosional forces on beach mix backfill. If channel dredging occurs in the future, the stability of a cap could be undermined and the commenters believed that the ROD should state how EPA would implement capping in this situation to prevent future slope failure.

#### EPA Response

For the purpose of the feasibility study, a set of generic cap designs successfully implemented at other sediment dredging superfund sites (like *GM Massena Superfund Site*, *Eagle Harbor Superfund Site*) were applied based on Site-specific conditions, including the need for reactive materials to contain PTW and armoring to prevent erosion of the cap material. To facilitate consistent application of capping technologies, all caps were assumed to be 36-inch thick and comprised of various combinations of sand, beach mix, activated carbon, organoclay, and armor stone. Additional considerations are presented in *Section D4. Cap Thickness Evaluation*, Appendix D of feasibility study report (USEPA 2016b). The actual composition and thickness of sediment caps that will provide long-term permanence will be determined during remedial design.

Therefore, the specific information in the feasibility study report associated with cap material, thickness of caps and/or types of cap layers were assumptions for the purposes of evaluating alternatives according to CERCLA criteria and developing cost estimates for the remedial alternatives. These assumptions were developed based on the existing data and will be finalized during the remedial design, after design level data to refine the baseline conditions are obtained.

During the remedial design, factors such as proximity to navigational channel, erosion associated with wind, ship scour, river currents and vessel-generated waves would be considered in accordance with the decision tree as part of remedial design to provide long-term effectiveness and permanence and balanced against habitat considerations. The ROD includes a flexible decision tree along with general

capping design requirements to guide the assignment of capping technologies, based on specific characteristics within SMAs. It is understood that some levels of armoring may require on or off-site mitigation, which will be considered during design and discussed with the services. Also, no capping would occur in designated navigation channels unless below the navigation depth, with an appropriate buffer/overdredge allowance in areas which may require dredging in the future.

#### 2.21.4 Identify and Stage Realistic Sediment Transload and Treatment Facilities

##### Comment Summary

Two commenters believed that EPA fails to thoroughly describe and consider parameters associated with the implementability of the remedial alternatives in identifying and staging realistic sediment transload and water and sediment treatment facilities. They stated that EPA's analysis fails to take reasonable account of the lack of suitable transload facilities (or extended construction times to ready upland sites for transloading operations), or of the shortages in available and qualified source material for capping activities (given the expected stringent import criteria including a PCB replacement value of zero).

##### EPA Response

As part of the feasibility study, EPA talked with the representative facilities for dredging, barging (Tidewater Transportation & Terminals), transloading, and disposal (ChemWaste, Port of Morrow-Boardman) in the area. None of these facilities indicated any significant concerns about logistics in handling large quantities of sediment. Portland Harbor is a working industrial waterway that has the necessary infrastructure to support large sediment remediation activities.

From experience with other sediment cleanups, the feasibility study assumed that that all necessary pretreatment (including dewatering dredged material, managing and treatment of wastewater generated during the dewatering process) and handling of dredge materials will occur on the barge prior to arrival at a transload facility or ultimate disposal facility. Although the feasibility study acknowledged that an on-site transload and materials handling facility could be sited, the cost estimates did not assume stockpiling of material on a particular upland facility nor at the transload facility. The water collected on barges could potentially be discharged to the lower Willamette River (with or without treatment in accordance with regulations, such as multistage solids removal) or disposal at a publicly owned treatment works facility after appropriate and required treatment. EPA acknowledges that an expanded treatment system may be required for some material, particularly PTW. Also from experience, it was assumed that the dredged material will be mixed with diatomaceous earth on the barge to absorb water along with gravity decanting, thus reducing the requirement for dewatering and water treatment during transload and transportation for disposal.

Also, the feasibility study report (USEPA 2016b) looks at modes of transport and associated transload of wastes from a macro perspective, but the primary assumption in the feasibility study was to use barges for the purposes of implementability and cost evaluation. The feasibility study also indicated that multiple modes of transport could be used and could be evaluated during remedial design phase of the project. Thus, the impact on rail and highway infrastructure within the City of Portland can be minimized. Various disposal facilities did not indicate to EPA any significant concerns about logistics of handling the required volume for transportation, transload and disposal. Even though there might be a heavy barge traffic, the transload for all dredged material may not be at the same location.

## 2.21.5 Consider Parameters Associated with Treating Large Volumes of Contaminated Sediment

### Comment Summary

Three commenters believed that EPA fails to thoroughly describe and consider parameters associated with the implementability of the remedial alternatives in potentially treating large quantities of sediment.

### EPA Response

The feasibility study report (USEPA 2016b) considered that the materials removed for ex-situ low temperature thermal desorption treatment is to be treated at an off-site disposal facility. The assumption used estimated the quantity of removed material for ex-situ treatment to be roughly 15,000 cubic yards or 12,600 tons (*Table D2.d. Treatment and Disposal Quantities (based on assumptions presented in Appendix D2.4 of 2016 feasibility study report)*). Assumed ex-situ treatment included low temperature thermal desorption treatment. The actual quantity of material which might require such treatment will be determined during design based on federal or state regulations and/or the off-site disposal facility.

EPA talked with the representative facilities including ChemWaste, Port of Morrow (Boardman) and the barging company (Tidewater Transportation & Terminals) and they did not indicate any significant concerns regarding the logistics of material handling as well as the amount that can be accept each day at the facility for ex-situ low temperature thermal desorption treatment or any issues with treatment limitations.

## 2.21.6 Consider Implementability in Terms of Community Acceptance of Short-Term Impacts

### Comment Summary

One comment stated that EPA fails to thoroughly describe and consider parameters associated with the implementability of the remedial alternatives in obtaining community acceptance, particularly of short-term impacts such as noise, light, and vehicle traffic.

### EPA Response

Based on comments received during the public comment period, EPA has thoroughly considered implementation impacts from community acceptance. EPA appreciates the concerns of the public, local workforce and businesses as important segments of the community as well as the desire expressed in many comments to reduce the impact due to remedy implementation.

EPA will develop a monitoring program during the remedial design phase and will consider public input (Section 2.17 of this responsiveness summary). Concerns about noise, odor, light, and other potential community impacts will also be considered and addressed to the extent possible. Exceedances of monitoring thresholds will result in additional controls being put in place so that construction impacts are mitigated to the extent practicable. EPA will provide contact information for community members to raise complaints or concerns during the course of construction.

Cleanup activities, including the use of dredges and barges will generally be consistent with existing uses of the river in terms of the level of noise, lighting, and human activity that already exists. During the construction period, there would be increased barge traffic as barges transport dredged material from the active cleanup area downstream. Cleanup activities with the potential to restrict navigation in the

harbor channel will be coordinated with the USACE, U.S. Coast Guard, and other stakeholders during remedial design.

### 2.21.7 Ensure Free Passage of Ship Traffic during Remediation

#### Comment Summary

Two commenters stated that EPA fails to thoroughly describe and consider parameters associated with the implementability of the remedial alternatives in placing obstructions to the navigation channel and the requirements to move the dredge and its support vessels and structures to allow for the passage of ship traffic on an ongoing and continuous basis. The following link provides an illustration of the impact of passing vessels on dredging (<http://dofnw.com/animation/>).

Additionally, the RM 11E Implementability Study Report found that several hundred vessels (ocean going ships, tug boats, and barges) use or traverse the RM 11E area every year, with vessels using over-water RM 11E facilities almost every day. The ROD should acknowledge these constraints.

#### EPA Response

Remedial activities with the potential to obstruct navigation temporarily in the harbor channel will be coordinated with the USACE and U.S. Coast Guard, including necessary containment measures to minimize sediment dispersion in areas where NAPL extends into the navigation channel.

In the feasibility study report (USEPA 2016b), sheet piles are considered as a representative engineered rigid control measure identified and evaluated for sediment dispersion control. However, that representative approach does not preclude other types of rigid control measures for consideration during remedial design. As stated in Appendix O of the report, EPA agrees that depth can limit the use of suitable engineered options for controlling releases, and deep water depths can preclude the use of sheet piles. EPA assumes that engineered rigid containment will be utilized when NAPL was present in water depths less than 50 feet. The feasibility study report acknowledges that “Release and residual management measures such as silt curtains and sheet piles may be difficult to construct and reliably operate in portions of the river affected by navigation traffic, deeper water, and significant current, this may lead to schedule and implementation delays.”

Engineered rigid control measures, which has the potential of obstructing the navigation channel, were evaluated holistically within the feasibility study report for their use in reducing or eliminating short-term releases of contaminants during construction and not on a location-specific basis. Thus, the feasibility study report does not present figures indicating design level logistical details regarding location and depth of engineered rigid control measures. Details (such as type and location) regarding engineered rigid control measures will be determined during remedial design.

Regarding the RM 11 area, The ROD acknowledges that, during remedial design and remedy implementation, various implementability factors such as dredge production rates, seasonal timing, and other factors will be considered to minimize facility closures and to avoid adverse economic impact to waterfront businesses.

### 2.21.8 Ensure Remediation Time Frames Are Realistic

#### Comment Summary

Many comments were received from LWG, other businesses and industry organizations regarding the construction durations utilized in the feasibility study. The majority of the commenters stated that the construction durations presented in the feasibility study were overly optimistic and did not take into

account the potential for delays associated with the time necessary to prepare dredging areas (such as, installation and removal of sheet pile wall and placement and removal of silt curtains), move operations from one dredge area to another, manage debris, implement construction related BMPs and place capping materials. They commented that the construction duration estimates did not account for siting and development of sediment and water staging, handling, treatment and transloading facilities. Finally, the commenters stated that the potential effects of process bottlenecks at the transloading/water treatment facilities, delays due to roundtrip transport to the disposal facility and lost time due to the requirement to move and reposition dredge vessels to avoid disrupting navigation were not considerations.

The commenters stated that failure to properly consider these factors inappropriately skewed the evaluation of dredging-based alternatives in the feasibility study. They further commented that the use of overly optimistic production rate assumptions and the related underestimation of dredging duration and costs precluded meaningful comparison of the cost effectiveness of remedial alternatives as required by the NCP and CERCLA. They also stated that these incorrect assumptions result in a preferred alternative that is not an accurate representation of the actual impact Alternative I would have on the community and operations within Portland Harbor.

A specialized dredging firm provided a detailed evaluation of the various construction durations presented in the feasibility study and proposed plan. The commenter stated that based on an evaluation of production rates achieved at environmental dredging projects in the Pacific Northwest, average open water and confined dredging production rates are 1870 and 1060 cubic yards per day respectively in comparison to the rates of 2382 and 1190 cubic yards /day used in the feasibility study. The commenter further concludes that based on a 17 week dredging season (July 1 through October 31), it would take an estimated 4.1 years of dredging with two dredges to implement dredging activities associated with EPA's preferred alternative which is approximately one-third longer than the 3.1 years of dredging estimated by EPA for two dredges operating in tandem.

One commenter cited the dredging activities implemented at the Boeing Plant 2 early action project as the basis for concluding that the dredging production rates were over estimated. The commenter noted that the dredged schedule of 20 hours per day, six days a week was met only 75 percent of the time. The primary factors that resulted in lower production rates included transload facility production rates, railcar availability, and down time for water treatment system. The same commenter also noted that EPA stated in an earlier version of the feasibility study that the daily and weekly durations of removal operations may be refined if community quality of life concerns (such as night-time noise or light pollution) are identified.

Finally, a LWG member commented that the proposed plan is unacceptably vague regarding the length of time between issuance of the ROD and commencement of construction of the remedy. EPA provides vague estimates by reference to a "Year 0" but does not articulate what must occur before or after Year 0 and how long those activities will take. For example, it is unclear whether entering into consent decrees, initial conditions sampling, remedial design (and any additional investigation), construction of a material handling facility and construction mobilization occur before or after Year Zero and how long each will take.

### **EPA Response**

The assumptions and calculations regarding dredged production rates were included in Appendix D, Table D3-1 of the 2016 feasibility study report (USEPA 2016b). The assumptions about factors such as

bucket volume, cycle time, and percent bucket fill are considered reasonable based on USACE guidance (*Technical Guidelines for Environmental Dredging of Contaminated Sediments*, September 2008 [USACE Environmental Dredging Guidelines], Table 1, page 88) (Palermo 2008) and the experience at other sediment remediation projects around the country and in the Pacific Northwest.

As noted in Table D3-1, daily dredge production rates were developed assuming a 55/45 percent mix of cable arm versus articulated bucket dredges, based on the approximate areal percentages of navigation channel and maintenance dredge areas in the alternatives. Based on the size of the Site and experience at other sites, dredging and excavation operations are assumed to occur 24 hours/6 days per week using three dredges. The feasibility study notes that the daily and weekly durations of removal operations may be refined if community “quality of life” concerns (such as nighttime noise or light pollution) are identified. However, due to the industrial nature of the Site and surrounding area, the feasibility study assumed that 24 hours per day dredging activities can be achieved. Section 2.17.4 of this responsiveness summary addresses quality of life monitoring concerns.

As described in Table D3-1, the planning-level productivity estimate for a cable arm dredge was developed based on operational characteristics for environmental dredging and guidance presented in the USACE Environmental Dredging Guidelines. The production rate is the product of the bucket volume (10 cubic yards), cycle time (2 minutes), and percent bucket fill (60 percent), adjusted for effective working time (62.5 percent).

The basis for specific assumptions (using USACE Environmental Dredging Guidelines) is summarized below:

- **Bucket Size:** USACE guidelines provide a cable arm bucket size of 3 to 10 cubic yards. As described in (USACE 2013), recent environmental dredging projects completed at Buffalo River and Indiana Harbor used 15 cubic yard buckets. As a result, a 10 cubic yard bucket size was selected.
- **Cycle Time:** USACE guidelines provide a cycle time of 2 to 4 minutes. As described in Schroeder and Gustavson, 2013, a typical cycle time without restrictions would be 1.5 to 2 minutes when dredging at depths greater than 35 feet. As a result, a 2-minute cycle time was selected.
- **Percent Bucket Fill:** USACE guidelines provides a percent bucket fill of 0.5 to 0.65. As a result, a percent bucket fill of 60 percent was selected.
- **Effective Working Time Efficiency:** USACE guidelines provides an effective working time of 55 to 70 percent. The selected value of 62.5 percent represents the mid-point of this range.

Based on these assumptions, the cable arm dredge productivity rate is approximately 2,700 cubic yards/day/dredge plant. The productivity estimates of the articulated bucket dredge are derived from recent site experience at Boeing Plant 2 removal at the Duwamish River Superfund Site. There, the daily production rate during the latest season of dredging was approximately 1,150 cubic yards/day using a single 4-cubic yard excavator-mounted bucket.

Regarding the estimate use of fixed arm vs. cable arm dredging, Table D3-1 states: “Daily dredge production rates were developed assuming a 55/45 percent mix of cable arm versus articulated bucket dredges, based on the approximate areal percentages of navigation channel and maintenance dredge areas in the alternatives.” Assuming a 55/45 percent mix of cable arm and articulated bucket dredges, a total production rate of 6,000 cubic yards/day was estimated for daily production as follows: [(55

percent \* 2,700 cubic yards/day) + (45 percent \* 1,150 cubic yards/day)] \* 3 dredge plants = 6,000 cubic yards/day estimates. It's acknowledged that the text in the main body of the feasibility study that is referenced by the commenters does not clearly state this basis.

A number of commenters stated that the time necessary to prepare dredging areas, move operations from one dredge area to another, manage debris, implement construction related BMPs and place capping materials, allowances for work disruption, and other impediments to dredging operations were not considered. However, consistent with the USACE Environmental Dredging Guidelines (p. 131), these factors are considered through the use of an "Effective Work Time Factor:" "Effective working time is the time during the dredging operations when actual production is taking place, such as material moving through the pipeline or being placed into a sediment barge. This is also referred to as 'operating time.'" The Effective Work Time factor accommodates "when the dredge is operational but no production is taking place, such as time spent making changes to pipelines, cleaning debris from the suction head, changing sediment barges, moving the dredge, standing by for navigation traffic, making minor operating repairs, and refueling. This is also referred to as 'allowable downtime.'" The USACE Environmental Dredging Guidelines (p. 93) states that the effective working time is "typically 55 to 70 percent for environmental dredging projects." The estimate used in the 2016 feasibility study (62.5 percent) was the midpoint of that range. In this regard, dredge "operating time" is estimated to occur 15 of 24 hours, six days per week. The effective working time factor was explicitly used to the accommodate issues identified by the commenters as well as other unforeseen circumstances. As further stated in the 2013 memorandum (USACE 2013):

*"A work schedule of 6 days at 24 hours/day with three dredge plants on site is recommended, equating to approximately 5,600 cubic yards per day with current production assumptions. To further refine this estimate, the cycle time, fill percentage and effective work time should be reviewed based on site-specific conditions, resuspension control plan and residuals management plan. The existing estimates for these parameters are conservative and typical of shallow cuts with stringent controls on overdredging, resuspension (e.g., silt curtains), and residuals. For example, thicker cuts could significantly increase the production rate. A target production rate of 6000 cubic yards/day, 6 days per week should be achievable even with the assumed efficiency impacts of resuspension control and residuals control and management if water quality, processing and disposal requirement can be met. A target production rate of 6000 cubic yards/day, 6 days per week should be achievable even with the assumed efficiency impacts of resuspension control and residuals control and management if water quality, processing and disposal requirement can be met."*

The feasibility study assumes that dredging and excavation operations to occur 24 hours/6 days per week using three dredges. Also, the duration of the dredging season is assumed to be 122 days based on the typical in-river fish work window (the work window is adjusted annually based on the actual runs by NMFS in consultation with Oregon Department of Fish and Wildlife) established for the Willamette River of July 1 through October 31. The daily and weekly durations of removal operations may be refined if community "quality of life" concerns (such as nighttime noise or light pollution) are identified. However, for this feasibility study report, it is assumed that 24 hours per day dredging activities can be achieved given the industrial nature of the majority of the surrounding areas. Also, it is assumed that other related construction activities will be performed in-parallel to the in-river work.

Overall, this and other comments on dredge production imply that overly high production rates falsely equate to shorter construction durations. Even if these feasibility study-level production rate estimates are high, other assumptions lessen the production rates. For example, the in-river construction duration is based on the assumption that “Cap and ENR construction is assumed to occur in sequence (not in parallel) with dredging for estimating total construction” (Table D3-1). This means that all dredging would occur, then all capping would occur. This assumption is reasonable for a feasibility study level evaluation of construction duration. However, it is likely or possible that remedial construction activities would be sequenced by area, generally moving from upstream to downstream, capping/dredging contaminated sediment, before moving on to the next area whenever possible which would reduce overall construction timeframe from the assumptions used for the feasibility study. As a final point, because all alternatives have dredging to some degree, changes to the dredge productivity rates would have similar effects across all alternatives, and not significantly influence remedy selection.

Once commenter provided alternate production estimates based on assumptions regarding bucket size, fill factor, bucket cycle time and effective working time also based on the USACE 2008 Environmental Dredging Guidelines and their experience with similar projects implemented in the Pacific Northwest. From our review of their analysis, that analysis compares favorably to assumptions used in the feasibility study. That review concluded that production rate could be 3740 cubic yards/day for two dredges operating in tandem, whereas, the EPA feasibility study estimated of 6,000 cubic yard/day using three dredge plants. In addition, the estimate of 4.1 years of dredging with two dredge plants is similar to the EPA estimate of 3.1 years of dredging for three dredges operating in tandem.

While various dredging production rates can be developed based on alternate assumptions regarding bucket volume, cycle time, percent bucket fill and effective working time, the assumptions used and production estimates resulting from them presented in the feasibility study are consistent with guidance and the experience at other sediment remediation projects around the country and in the Pacific Northwest and represent an appropriate level of accuracy for a feasibility study level evaluation. In addition, any uncertainty in construction duration does not skew the evaluation of alternatives since the dredge production estimates were developed in a consistent manner across all alternatives. Similarly, although the feasibility study and proposed plan (USEPA 2016c) did not consider the length of time between the ROD and the commencement of remedial activities at the Portland Harbor Site, this length of time is expected to be consistent between alternatives and thus has no bearing on the selection of EPA’s preferred alternative because it does serve to distinguish one alternative from another.

Regarding the length of time that construction would take in comparison to MNR, it should be noted that the estimated construction duration for Alternative F Modified is 13 years while MNR is expected to take much longer. In addition, without the targeted removal and capping associated Alternative F Modified, MNR is expected to be much less effective.

### 2.21.9 Ensure Cleanup Does Not Impact Site Features

#### Comment Summary

The City of Portland, Port of Portland, Sediment Management Work Group, and the RM 11 – PacifiCorp all expressed concern that EPA needs to consider outfalls, water mains, sanitary lines and other utilities, bridges, docks and other infrastructure, maritime and bridge traffic, terminal operations, existing remedial caps and shoreline stabilization, steep slopes, buried/under water power/utility cables, and areas to manage dredged materials in the assignment and implementation of remedial technologies. The City called to attention a water main and sanitary force main that cross the river. They requested EPA consider current and future utilities, and use precautionary measures to assure protection and long

term access of public utilities. The City also commented that the cost of relocation or alteration of utilities as well as future associated maintenance costs should be factored into remedy costs.

### **EPA Response**

EPA considered overall site information to determine general feasibility of capping, dredging and application of other remedial technologies. Details of public utilities and other site features will be considered during remedial design. EPA agrees that it will be necessary to plan and take precautions to prevent damage, destabilization and other adverse impacts during construction. If impacts are unavoidable, precautions will be taken to minimize impacts as much as practicable and damage will be repaired. During remedial design, site-specific surveys will be conducted to identify public utilities and infrastructure in order to account for these features in the remedial design, which may mean working around them or in some cases relocating such features. Parties planning and/or performing the cleanup will need to coordinate with landowners on details of infrastructure protection, or alternately, details of infrastructure relocation where necessary. Any proposed changes or disturbance to utilities or access of utilities will be coordinated with the City of Portland and others.

Additionally, other site-specific details will be evaluated and considered during remedial design. Specific schedules for maritime and bridge traffic and terminal operations, materials management and other higher coordination considerations will also be factored into planning during the remedial design and the construction planning process. For additional information on dredged material handling, see Appendix F of the feasibility study report (USEPA 2016b). Debris is discussed in Sections 3.4.6.3 and 3.4.8.6 of the feasibility study report. Additional responses to concerns related to river banks and dredging can be found in the dredging and river banks response to comments.

## **2.22 Cost**

### **2.22.1 Perform a Cost Effectiveness Analysis**

#### **Comment Summary**

Eight commenters stated that EPA failed to perform a clear cost-effectiveness analysis. It was stated that a quantitative assessment of cost-effectiveness is needed and that CERCLA requires that EPA determine that the selected remedy is cost-effective. The commenters stated that EPA must compare the cost to the effectiveness of each alternative individually, fairly and carefully weighing the costs against the benefits of the alternatives both individually and relative to each other. This evaluation should also demonstrate how the alternatives' dollar costs are proportional to their effectiveness in reducing risk.

The commenters state that EPA's proposed plan and feasibility study report omit quantitative and detailed short-term and long-term effectiveness evaluations and repeatedly underestimate the costs and durations of the alternatives. It was stated that EPA's limited cost-effective analysis in the proposed plan is insufficient to meet the standards set forth in statutes, regulations and guidance and risks a determination that its ultimate remedy selection is arbitrary and capricious. Commenters further state that due to the perceived uncertainty in the cost analysis, PRPs will be discouraged from committing to the cleanup and entering into liability settlements.

#### **EPA Response**

A cost-effectiveness determination is required as part of the two-step remedy selection process indicated at 40 CFR §300.430(f). Specifically, 40 CFR §300.430(f)(ii)(D)) describes how cost-effectiveness is determined as:

*Cost-effectiveness is determined by evaluating the following three of the five balancing criteria to determine overall effectiveness: long-term effectiveness and permanence, reduction of toxicity, mobility, or volume through treatment, and short-term effectiveness. Overall effectiveness is then compared to cost to ensure that the remedy is cost-effective. A remedy shall be cost-effective if its costs are proportional to its overall effectiveness.*

Page 67 of the proposed plan (USEPA 2016c) described EPA's analysis of the relevant criteria in compliance with the NCP. Likewise, the ROD at Section 15 provides EPA's analysis and determination of cost-effectiveness as provided by the NCP. Table 29 in the ROD addresses the elements of cost-effectiveness.

Neither the statute nor the NCP requires the type of rigorous tools, such as a "multi-criteria decision analysis" for determining cost-effectiveness as suggested by multiple commenters. Per the NCP [40 Code of Federal Regulations 300.430(e)(9)], the feasibility study report (USEPA 2016b) included a qualitative and comparative analysis of the individual balancing criteria of long-term effectiveness and permanence, reduction of toxicity, mobility, or volume through treatment, short-term effectiveness, implementability, and cost. The feasibility study comparative analysis has been updated to include Alternative F Modified (See ROD Table 22). And, as discussed above, the ROD includes the agency's determination of how the selected remedy (Alternative F Modified) is cost-effective as the NCP provides, see ROD Section 15.

### 2.22.2 Provide Costs by SDU

#### Comment Summary

Comments from Knife River, ESCO and Northwest Pipe request cost estimates on a SDU/SMA basis for allocation/negotiation purposes. Northwest Pipe also asked for a break-down of costs for various technologies. Comments from Shell Oil, Shore Terminal and SLR International question/challenge EPA's delineation of SDUs (or in some cases, SMAs).

#### EPA Response

The purpose of the feasibility study cost estimates, as stated in EPA guidance, is not to create allocation estimates, although they can be used as a starting point for that purpose. The selected remedy is a site-wide remedy decision and costs estimates were not broken-down down by SMA/SDU and by remedial technology. Specific questions noted in the Shell Oil comment letter regarding Table 4.1-1 of the feasibility study report (USEPA 2016b), which summarizes the SDUs, including the focused COCs identified for each of the SDUs, will be evaluated, along with the complete list of COCs during remedial design to ensure cleanup levels are met. During remedial design, additional data and/or re-evaluation of existing data will be considered, such as the sediment data at RM 5W referred to in the comment letter from Shore Terminals. Similarly, remedial action boundaries/SDUs will be re-evaluated during remedial design.

### 2.22.3 Provide Detail and Backup For Estimated Costs of Each Alternative

#### Comment Summary

Six comments stated that EPA's estimated costs for each alternative lack detail, accuracy, and backup.

#### EPA Response

EPA documented the methodology and assumptions used in developing feasibility study cost estimates in Attachment A of Appendix G of the 2016 feasibility study report (USEPA 2016). Cost estimates were developed consistent with "A Guide to Developing and Documenting Cost Estimates during the Feasibility

*Study*” (USEPA 2000) and include the level of detail and backup suggested by the guidance to meet the accuracy requirements for feasibility study cost estimates (-30 percent to +50 percent of actual cost). EPA recognizes that the intended purpose and use of cost estimates during a feasibility study for remedial alternatives may be misunderstood by those not familiar with the Superfund process, leading to the incorrect perception that feasibility study report cost estimates are “inaccurate” or not the “true” costs. EPA cost estimating guidance (USEPA 2000) states that the purpose for feasibility study cost estimates is to compare remedial alternatives during the remedy selection process, not for establishing construction project budgets nor for negotiating Superfund settlements with potentially responsible parties to pay for cleanups.

The expected accuracy stated in this guidance for feasibility study cost estimates is +50 percent to -30 percent of actual cost, which means that a remedial alternative’s cost at the time of construction could be as much as 50 percent higher or 30 percent lower than as presented in the feasibility study report. These estimates are not intended to be highly accurate because the level of detail for the scope of the alternatives in a feasibility study is much lower than later during design and construction of a remedy when more data are available and there is a better understanding of the construction timelines and funding. This is particularly true of projects such as the Portland Harbor cleanup where a large number of individual parties potentially contributed to the contamination and the scope of the cleanup is large (over many river miles), so the sequencing of construction work is complex. The cost estimates are developed to reflect the understanding of the alternatives as described in the feasibility study given the understandable uncertainties that exist and will continue to exist even after a decision on a remedy approach is made, prior to design and construction.

The cost estimate backup as presented in Appendix G also includes Cost Source Database; EPA Derived Labor Costs; Project-Specific Vendor Quotes; Previously Developed Costs by Anchor QEA; EPA Derived MII Costs; and Costs from Other Projects/Sources.

#### 2.22.4 Improve Accuracy of Production Rates, Durations, and Schedule

##### Comment Summary

Ten commenters stated that EPA needed to improve the accuracy of production rates, project durations, and schedules. Commenters state that dredging and capping production rates used by EPA were too high, resulting in unrealistic unit costs and construction durations. Commenters state that due to the high level of commercial activity at the Site, additional time should be added to the schedule to allow for commercial ship passage. They further state that EPA’s underestimated durations result in inaccurately low estimates for other cost elements, such as the transload facility and treatment.

##### EPA Response

During the feasibility study, a cursory evaluation of construction duration was performed for the major construction components (capping and dredging) as indicated in Appendix D.3 of the feasibility study report (USEPA 2016b). A detailed construction schedule is generally not produced because the level of scope definition is too low to make those design-level determinations. It should be noted that schedules indicate a minimum duration and that longer durations only affect present value cost as estimated. The productivity rates presented in a technical memorandum (*Review and Recommendations on Dredge Duration and Production Rates from the Portland Harbor Draft Feasibility Study*) (USACE 2013) was used to calculate construction durations.

The USACE technical memorandum recommended that:

*“A work schedule of 6 days at 24 hours/day with three dredge plants on site is recommended, equating to approximately 5,600 cubic yards per day with current production assumptions. To further refine this estimate, the cycle time, fill percentage and effective work time should be reviewed based on site-specific conditions, resuspension control plan and residuals management plan. The existing estimates for these parameters are conservative and typical of shallow cuts with stringent controls on overdredging, resuspension (e.g., silt curtains), and residuals. For example, thicker cuts could significantly increase the production rate. A target production rate of 6000 cubic yards/day, 6 days per week should be achievable even with the assumed efficiency impacts of resuspension control and residuals control and management if water quality, processing and disposal requirement can be met. A target production rate of 6000 cubic yards/day, 6 days per week should be achievable even with the assumed efficiency impacts of resuspension control and residuals control and management if water quality, processing and disposal requirement can be met.”*

The assumptions and calculations transmitted in the memo were included in Appendix D, Table D3-1 of the 2016 feasibility study report to estimate construction durations for each alternative. Contrary to assertions made in the comment, stepping time, allowances for work disruption, and other impediments to dredging operations are accommodated in productivity rate estimates in the USACE technical memorandum. USACE's *Technical Guidelines for Environmental Dredging of Contaminated Sediments* (Palermo 2008) recommends the use of an Effective Working Time factor (p. 131): “Effective working time is the time during the dredging operations when actual production is taking place, such as material moving through the pipeline or being placed into a sediment barge. This is also referred to as “operating time.” The Effective Work Time factor accommodates “when the dredge is operational but no production is taking place, such as time spent making changes to pipelines, cleaning debris from the suction head, changing sediment barges, moving the dredge, standing by for navigation traffic, making minor operating repairs, and refueling. This is also referred to as “allowable downtime.” USACE 2008 (p. 93) states that the Effective Working Time is “typically 55 to 70 percent for environmental dredging projects.” The estimate used in the 2016 feasibility study report (62.5 percent) was the midpoint of that range. In this regard, dredge “operating time” is estimated to occur 15 of 24 hours, six days per week. The Effective Working Time factor was explicitly used to accommodate issues identified by the commenters as well as other unforeseen circumstances. As stated in the 2013 memo from (USACE 2013), “A target production rate of 6000 cubic yards/day, 6 days per week should be achievable even with the assumed efficiency impacts of resuspension control and residuals control and management if water quality, processing and disposal requirement can be met.”

Based on recommendations (Palermo 2008), the feasibility study assumes that dredging and excavation operations occur 24 hours/6 days per week using three dredges. The daily and weekly durations of removal operations may be refined if community “quality of life” concerns (such as nighttime noise or light pollution) are identified. However, for this feasibility study, it is assumed that 24 hours per day dredging activities can be achieved given the industrial nature of the majority of the surrounding areas.

The project/construction durations are not entirely dependent upon dredging production rates. They are dependent on other assumptions that increases the project/construction durations, for example; the in-river construction duration is based on the assumption that “Cap and ENR construction is assumed to occur in sequence (not in parallel) with dredging for estimating total project/construction duration” (Table D3-1). This means that all dredging would occur, then all capping would occur. This assumption is fine for its purpose (estimating a project/construction duration for a feasibility study -level evaluation). As a final point, because all alternatives have dredging to some degree and used the same

types of technology assignments (capping, dredging and disposal, in-situ treatment, ENR, etc.), changes to the dredge productivity rates would have similar effects across all alternatives, and not significantly influence remedy selection.

It should be noted, that construction durations for each alternative were estimated exclusively from the information provided in Appendix D; the information in Appendix G was not used in any way to calculate the construction durations that were ultimately used and presented in the 2016 feasibility study report for both cost and non-cost purposes in evaluation of balancing criteria. The information regarding productivities and dredge/capping/disposal crews in Appendix G was used solely to verify that unit costs provided for the various scope activities in the cost estimates had reasonable cost accuracy for a feasibility study level of evaluation.

The feasibility study does not provide construction schedules for alternatives, which is more appropriate during remedial design. However, cursory evaluations of project durations within Appendix D3 were included for purposes of implementability and cost evaluations in the feasibility study. The feasibility study assumes that the development of transload facility will be included in the initial year of preparatory activities. The assumption of preparatory activities occurring in the initial year is stated in Footnote K, Table D3-1 (Construction Duration Assumptions) of Appendix D of the feasibility study report. The initial year of preparatory activities would include pre-design investigations and start-up activities prior to beginning construction (in-river work) and would include development of transload facility, mobilization, setting up of staging area, etc. Also, the feasibility study assumes that all necessary pretreatment (including dewatering and water treatment) and handling of dredge materials will occur on the barge prior to arrival at a transload facility. There is no assumed stockpiling of material on-site nor at the transload facility. Expansion of the transload facility or additional transload facilities (if needed) was assumed to be developed concurrently during construction (in-river work) for feasibility study purposes.

In conclusion, the information in Appendix G is solely for cost estimating purposes and has no direct relationship to the estimated construction durations, which were estimated in Appendix D3 and used for cost and non-cost evaluations in the feasibility study report. The primary sources of information for construction duration estimates in Appendix D3 were the quantities in Appendix D2, the assumptions and footnotes from Table D3-1, and the productivities and equipment assumptions from the technical memorandum (Palermo 2008).

### 2.22.5 Modify Contingency Percentages

#### Comment Summary

Six comments were received regarding modification of contingency percentages. They state that EPA used a low contingency percentage and that this is unwarranted due to the conceptual nature of the technology assignment modeling and the high level of uncertainty in applying these conceptual technologies.

## EPA Response

As described in Section 5.4 of *“A Guide to Developing and Documenting Cost Estimates during the FS”* (USEPA 2000), engineering judgment may be used to adjust rule-of-thumb percentages presented in Exhibit 5-6 for scope contingency with a lower contingency indicating that project scope will undergo minimal change during design. Due to the detailed level of conceptual design performed as part of the technology assignment modeling in this feasibility study, the contingency percentages were modified to the low end of the recommended range presented in the guidance, to better reflect the detailed evaluation and concepts developed for these items.

Per guidance, contributing factors to scope contingency include the following:

- Limited experience with certain technologies
- Inaccuracies in defining quantities or characteristics
- Potential requirements due to regulatory or policy changes

Scope contingency would be expected to be higher for newer or emerging remedial technologies than for more well-documented systems. Each alternative was developed using similar technologies and major work activities. Conventional and proven technologies were used in the development of the alternatives.

The primary differences between the alternatives is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. The development of the RALs for each alternative established a boundary for the horizontal limits of dredging/capping based on available boring data. There is a vertical limit for dredge volumes in the shallow and intermediate areas based on the technology assignments, and this will limit the risk for potential growth of volume estimates in those areas.

EPA ultimately selected a scope contingency (10 percent) within the parameters suggested by the guidance, after taking this information into account. For instance, Exhibit 5-6 of EPA guidance (USEPA 2000) indicates a recommended scope contingency range of 5 to 10 percent for surface grading/diking, 5 to 15 percent for bulk liquid processing, 5 to 15 percent for on-site and off-site disposal, and 10 to 20 percent for sludge stabilization. All of these are activities that are part of the scope of the Portland Harbor alternatives and are within the range of the scope contingency selected by EPA. While vertical barriers (10 to 30 percent) and soil excavation (15 to 55 percent) are at or higher than the selected value, the refined development of quantities and scope in this feasibility study minimize the likelihood that significant unknowns and uncertainties remain that would result in large underestimation of costs requiring scope contingency.

Bid contingency accounts for changes that occur after the construction contract is awarded. Examples include:

- Technological, geotechnical, and other unknowns applicable to the construction phase
- Changes due to adverse weather
- Material or supply shortages

Conventional and proven technologies were used in the development of the alternatives with only few exceptions because of limitations in alternative development. Technical and geotechnical unknowns associated with constructing technologies such as sheet pile should be addressed during pre-design investigation. The site-specific unit costs developed for Portland Harbor and presented in Appendix G were generally in the range of costs at other contaminated sites in the Pacific Northwest. Inputs and assumptions used in the development of the construction duration calculations included an in-river work window which is appropriate for the region.

A vast majority of the materials and supplies identified as necessary for remedial action are conventional and readily available (sand, rock, diatomaceous earth, quicklime). EPA assumes commercial source of capping materials, and confirmed that commercial suppliers could supply the required volumes, which ultimately reduces concerns about cost growth due to material shortages. Similarly, the representative disposal facilities were contacted to verify that they did not have capacity or waste type limitations leading to issues during construction.

EPA ultimately selected a bid contingency (10 percent) within the parameters suggested by the guidance, after taking this information into account. Pages 5-11 of the guidance (EPA 2000) indicates a recommended scope contingency range of 10 to 20 percent.

Unlike alternatives for some Superfund projects, the primary differences between the alternatives for the Portland harbor Superfund Site is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. Because the differences in capital and periodic costs are primarily based on quantity differences, the use of lower percentages for contingency do not impact the comparative aspects of the costs estimates between alternatives.

### 2.22.6 Revisit Costs for Water Quality Control Structures

#### Comment Summary

Two comments were received on water quality control structures. Commenters state that although EPA is requiring the installation of sheet piles around PTW dredge areas in deep water, the cost estimate was based on less reinforced structures in shallow water.

#### EPA Response

Sheet piles are a representative engineered rigid control measure identified and evaluated for sediment dispersion control in the 2016 feasibility study report (USEPA 2016b). However, that representative approach does not preclude other types of rigid control measures for consideration during remedial design. As stated in Appendix O, EPA agrees that depth can limit the use of suitable engineered options for controlling releases, and deep water depths can preclude the use of sheet piles. EPA assumes that engineered rigid containment will be utilized when NAPL is present in water depths less than 50 feet.

Engineered rigid control measures were evaluated holistically in the 2016 feasibility study report for their use in reducing or eliminating short-term releases of contaminants during construction and not on a location-specific basis. Thus, the 2016 feasibility study report does not present any design level logistical details regarding location and depth of engineered rigid control measures. Location-specific evaluations for feasibility of sheet pile versus other types of engineered rigid control measures, including placement within the navigation channel, were beyond the scope of evaluation of the 2016

feasibility study report. Details regarding sediment dispersion control and location-specific engineered rigid control measures will be determined during remedial design which is the appropriate time for those types of evaluations.

Alternative-specific costs for purchasing, installing and removing sheet pile walls are presented in Appendix G. The unit costs were developed by Anchor QEA in the draft 2012 feasibility study on a horizontal linear foot basis. Quantities for sheet pile lengths used in the detailed alternative cost estimates and presented in the 2016 feasibility study report Appendix D Table D2.j (in horizontal linear feet) were holistically estimated for each alternative by encircling all PTW dredge and/or capped areas with silt curtains assumed for the remainder of dredged and/or capped areas.

Figure 3.4-33 of the 2016 feasibility study report presents areas of NAPL presence and Site bathymetry identifying water levels at the 50 feet below mean low water level. EPA acknowledges that the legend of Figure 3.4-33 should indicate that the darker shaded areas identify water depths greater than 50 feet MLLW, and the lighter shaded areas identify water depths less than 50 feet mean low water level.

Remedial activities with the potential to restrict navigation in the harbor channel will be coordinated with the USACE during remedial design, including efforts to minimize sediment dispersion in areas where NAPL extends into the navigation channel. The Rivers and Harbors Act prohibits obstructions to navigation, but CERCLA requires remedies to be protective of human health and the environment, and other federal statutes require measures to reduce impacts to Endangered Species Act species or the aquatic environment as well. It was assumed in the 2016 feasibility study report that the review for compliance with the substantive requirements of the relevant ARARs will occur during remedial design and throughout the construction of the cleanup as appropriate. However, permits and related administrative approvals, as implied by LWG, are not required for on-site CERCLA remedial actions and would not necessarily prevent implementation of these measures.

### **2.22.7 Provide Details on Dredging Equipment, Sediment Handling and Disposal, and Implementability**

#### **Comment Summary**

Comments were received from four commenters in reference to needing additional details on dredging equipment, sediment handling and disposal, and implementability. Commenters cite specific concerns about the capacity of offloading facilities to handle the estimated quantities of material and the ability to transport the material from the offloading facilities to the respective landfills in a safe and cost-effective manner.

#### **EPA Response**

In the 2016 feasibility study report (USEPA 2016b), the estimated use of fixed arm vs. cable arm dredging is presented in Table D3-1. It states that “Daily dredge production rates were developed assuming a 55/45 percent mix of cable arm versus articulated bucket dredges, based on the approximate areal percentages of navigation channel and maintenance dredge areas in the alternatives.” Also, based on this assumption of mix of dredge types, 6,000 cubic yards/day was estimated for daily production  $[(55 \text{ percent} * 2,700 \text{ cubic yards/day}) + (45 \text{ percent} * 1,150 \text{ cubic yards/day})] * 3 \text{ dredge plants} = 6,000 \text{ cubic yards/day}$ .

The 2016 feasibility study report looks at modes of transport and associated transload of wastes from a macro perspective, but the primary assumption in the report was to use barges for the purposes of

implementability and cost evaluation. The report also indicated that multiple modes of transport could be used and could be evaluated during remedial design phase of the project.

EPA talked with the representative facilities including ChemWaste, Port of Morrow (Boardman site) and the barging company (Tidewater Transportation & Terminals) and they did not indicate any significant concerns about logistics of transload of NRC/NAPL PTW waste volumes for transport and disposal at ChemWaste. It should be noted that Tidewater Transportation & Terminals was the barging company used for the Gasco Early Action. Also, through discussions with the representative facilities, the cycle time in terms of barging and trucking reflects their cycle time input for a round trip. Based on these discussions and inputs, the following cycle time for barging was assumed in the feasibility study cost estimates: 1 day of barge time to Port of Morrow (Boardman site) and 18 hours of barge time for return.

The 2016 feasibility study report cost estimate does not assume that the barged material would be stockpiled at the Port of Morrow (Boardman site) transload facility. Instead the 2016 feasibility study report cost estimate assumes direct loading in two steps; using a crane to offload from barge and a front-end loader to load the trucks, as a representative process. In addition, an off-site transload facility development cost was included to account for additional flexibility in transload. In terms of flexibility, as indicated in Appendix F of the 2016 feasibility study report, multiple modes of transport besides barging (rail or truck) could be used to transport waste to ChemWaste from transload locations as determined during remedial design. It should be noted that ChemWaste had indicated for budgetary purposes for the feasibility study that the cost of transport would not differ significantly between the various modes of transport once transload was taken into account.

The ChemWaste landfill is assumed to only be used for disposal of NRC/ NAPL PTW. As compared to the Gasco Early Action (~15,000 cubic yards), the Site remedial action will generate a large volume of waste material for disposal at ChemWaste (~359,000 cubic yards); however, this volume is assumed to be generated over a longer construction duration than the Gasco Early Action. Based on these assumptions, it is estimated that approximately 2,400 cubic yards per week (which is approximately 1 to 2 barges per week) would be handled at the transload facility for disposal at ChemWaste. As mentioned above, the barging company, the transload facility, and disposal facility did not indicate any significant concerns about logistics of handling the required volume for transportation, transload and disposal.

The assumption in the 2016 feasibility study report for contaminated sediment disposed of at a Subtitle D facility is that it is barged to Bingen and hauled by truck to Roosevelt Landfill. EPA did have a discussion with Roosevelt Landfill facility about their ability to transload material from barge and they indicated the ability to accommodate the quantity that the project may develop, specifically including their ability to handle 6,200 cubic yards/day of dredged material. They also indicated that there are sufficient options available since Roosevelt Landfill facility has agreements with a number of transload facility locations along the Columbia River. As has been demonstrated on the Gasco and Terminal 4 early actions, transload facilities can be efficiently built and optimized to suit the needs of the Portland Harbor cleanup in a vicinity to landfills that often reduces greenhouse gas emissions by extending barge or rail haul mileage, and minimizes truck haul mileage.

### 2.22.8 Provide Dredge Volume and Cap Overplacement Costs

#### Comment Summary

One commenter had concerns with the dredge volume and cap overplacement costs. The commenter believes it is prudent to assume some additional amount of contamination beneath unbounded cores, and states that EPA did not include an overplacement allowance.

#### EPA Response

Comments were received from six commenters stating that EPA's estimated costs for each alternative lack EPA developed dredge volumes using "neat" line volumes based on interpolated area and depth data. To take into account side slope stability (dredge prism), neat volumes were multiplied by a factor of 1.5 to estimate the Low Volume with Overdredge, and by a factor of 2.0 to estimate the High Volume with Overdredge. Total volumes for each alternative were calculated as the average of the estimated low and high overdredge volumes. This is consistent with information presented in the USACE's Technical Guidelines for Environmental Dredging of Contaminated Sediments (Palermo 2008) – Section 3.4.3:

*"For feasibility study level considerations, an adjustment factor of 50 percent (i.e., an estimated dredge prism volume equal to 1.5 times the neat line prism volume) is appropriate for typical site conditions."*

Guidance states that the ratio of dredge prism (including allowable overdraft/overdredge) to the neat line prism can be as high as 3 based on work at the U.S. Navy Homeporting project in Everett, Washington.

Thus, the estimated dredge volume using the dredge prism to neat line ratio of 1.5 – 2.0 is reasonable for Portland Harbor and consistent with the guidance for a feasibility study level evaluation where the primary purpose is for comparing remedial alternatives during the remedy selection process.

For the purpose of the feasibility study, a set of generic cap designs was developed to be applied based on site-specific conditions, including the need for reactive materials to contain PTW and armoring to prevent erosion of the cap material. To facilitate consistent application of capping technologies, all caps were assumed to be 36-inch thick and comprised of various combinations of sand, beach mix, activated carbon, organoclay, and armor stone. The precise composition and thickness of sediment caps will be determined during remedial design.

### 2.22.9 Explain Mobilization and Demobilization Costs

#### Comment Summary

One comment was received from LWG regarding mobilization. The commenter states that EPA used a very low percentage of direct capital costs to estimate mobilization/demobilization costs instead of estimating likely costs based on project duration and scope.

#### EPA Response

LWG is correct that construction data were not specifically used for determination of the mobilization/demobilization factor. However, EPA's "A Guide to Developing and Documenting Cost Estimates during the Feasibility Study" (USEPA 2000), actual construction data are not required to be solely used. As indicated on page 5-6 of that guidance, "experience with similar projects, **including both estimates and actual costs** (bold emphasis added) can also be used as a source of cost data."

In addition, the determination of the percentage of the capital and periodic costs for mobilization and demobilization was based not just on review of Lower Duwamish River feasibility study, but also the Passaic River feasibility study, projects of similar scope and the equipment proposed for Portland Harbor. The types of dredge and cap placement equipment proposed in the Portland Harbor 2016 feasibility study report (USEPA 2016b) (the primary pieces of equipment requiring mobilization/demobilization from beyond metro Portland) are fairly conventional in that they are barge mounted excavation and placement equipment and not unique types of dredge equipment such as suction dredges. In addition, the number of dredge plants and capping plants and attending scow barges and tugboats are relatively small given the duration of the project. EPA has thus assumed mobilization and demobilization are representative of expected regional mobilization and demobilization costs. Procurement of any specialized equipment (such as double hull spill preventative barges) would not be cost-prohibitive with proper planning before implementing the selected remedy.

The use of a percentage of capital costs for mobilization and demobilization of equipment is reasonable for the feasibility study level of scope detail and assumptions. Real construction data will be evaluated and presented during remedial design as necessary.

It should be noted that unlike alternatives for some Superfund projects, the primary differences between the alternatives for the Portland harbor Superfund Site is the size of the footprint of removal and containment based on the area of the SMAs defined for each alternative. Therefore, the cost differences between alternatives is reflective of the differing quantities calculated in the technology assignment modeling. Because the differences in capital and periodic costs are primarily based on quantity differences, the use of lower percentages for mobilization/demobilization costs does not impact the comparative aspects of the costs estimates between alternatives. Also, it should be noted that the feasibility study cost estimates are not to be used for construction budgets, allocation, or Superfund settlements.

### 2.22.10 Explain Indirect Costs

#### Comment Summary

Comments were received from four commenters regarding indirect costs. Commenters state that EPA used very low end percentages for remedial design, project management, and construction management estimates.

#### EPA Response

EPA's *"A Guide to Developing and Documenting Cost Estimates During the Feasibility Study"* does not use the term "indirect costs" for the reasons stated on page 2-5 of that guidance; thus, the response uses the more appropriate term "professional/technical services costs". As described in Section 5.5 of that guidance, engineering judgment may be used to adjust rule-of-thumb percentages presented in Exhibit 5-8 for the professional/technical services costs of project management, remedial design, and construction management as well as the recommended range presented for technical support. As described in Attachment A of Appendix G of the feasibility study report (USEPA 2016b), the percentages of professional and technical services costs will be higher for projects of smaller scope and lower for projects of larger scope. Due to the high overall costs for major work activities, the professional/technical percentages were modified to lower than the recommended range presented in the guidance, to better reflect realistic costs for professional/technical services costs for these items.

The scope of the cleanup activities within the Site (thousands of acres) is much larger than the scope of the Head of the Hylebos project (tens of acres), and therefore it is expected that the percentage for remedial design costs and categories including project management and mobilization/demobilization used as a function of capital costs will be higher for the Head of Hylebos project and lower for the Site.

The remedial design costs presented in the 2016 feasibility study report for each alternative were estimated to be comparable to remedial design costs estimated for alternatives evaluated in the Lower Duwamish feasibility study report, when reviewed on an annualized basis. The specific scope and costs for the “initial conditions assessment, subsequent pre-remedial design investigations, or additional river bank sampling and remediation” will be identified during remedial design based on factors such as funding, phasing, and scheduling of work. Unknowns or unforeseen conditions for these activities and related costs not entirely captured in the remedial design percentage can be considered to be captured in the scope contingency applied to each alternative.

### 2.22.11 Include Department of State Lands Fees

#### Comment Summary

Three commenters requested that Department of State Land’s fees be accounted for in the cost determinations. Commenters state that Department of State Lands fees need to have a separate line item and point to the discrepancy between EPA and PRP estimates of the percentage of project management costs that the fees would represent.

#### EPA Response

Department of State Lands propriety authorizations, which include lease fees, were not included in the cost estimates. EPA acknowledges that the State Land Board through the Department of State Lands - promulgated rules for granting and renewal of access authorizations, leases, and easements issued to facilitate remediation conducted pursuant to an order issued by DEQ or EPA and habitat restoration activities in, on, under or over state-owned submerged and submersible land. However, Section 104 of CERCLA, 42 U.S.C. Section 9604 provides the President with broad authority to take response actions determined necessary to protect the public welfare and the environment from releases or the potential threat of a release of hazardous substances or pollutants and contaminants to the environment presenting an imminent and substantial endangerment to public health and welfare.

Section 104(e)(3) specifically provides the President authority to access “[a]ny vessel, facility, establishment, or other place or property where entry is needed to determine the need for response or the appropriate response or to effectuate a response action under” CERCLA. 42 U.S.C. § 104(e)(3). Furthermore, Section 121(e)(1) of CERCLA provides that: “[n]o federal, state, or local permit shall be required for the portion of any removal or remedial action conducted entirely on site, where such remedial action is selected and carried out in compliance with” CERCLA. 42 U.S.C. § 121(e)(1). If EPA were to perform the remedy, the United States would not be required to pay state fees. However, EPA expects most, if not all, of the remedy (cleanup actions) will be performed by PRPs and EPA anticipates that PRPs will negotiate reasonable terms and conditions of access to private and state-owned property to implement the remedy likely will be the subject of future negotiation between the PRPs, landowners, and Department of State Lands. The selected remedy overall is expected to improve the sediment and surface water quality of the river. EPA’s selected remedy seeks to minimize land and river use restrictions, while also assuring long-term protectiveness and a cost-effective cleanup. EPA encourages performing PRPs to coordinate with Department of State Lands early during remedial design to negotiate access and find further ways to reduce land and river use restrictions and, if relevant, diminution of property values.

## 2.22.12 Explain the Selection of the Discount Rate

### Comment Summary

Eight commenters stated that they believed that the discount rate that was used in the cost calculations was too high. Commenters state that the 2.3 percent discount rate used by PRPs is consistent with EPA guidance and that EPA's 7 percent discount rate is practically (and potentially legally) unachievable.

### EPA Response

As discussed in *"A Guide to Developing and Documenting Cost Estimates during the Feasibility Study"* (USEPA 2000), the real discount (interest) rate used for present value analysis in the feasibility study depends on whether a site is classified as a federal facility site. Federal facility sites are former or current installations operated or controlled by a federal government agency and identified by EPA's Federal Facilities Restoration and Reuse Office. The Site is not a federal facility. In addition, the guidance specifically mentions that although a federal-lead site cleaned up by EPA using the Superfund trust fund (fund-lead sites) may be an analogous situation to a federal facility site being cleaned up using Superfund authority, there is always a chance that a PRP could remediate the site. Thus, per guidance a real discount rate of 7 percent should be used in calculating present value costs for all non-federal facility sites such as the Site. This expectation is documented in the last paragraph of Page 4-5 of the guidance.

The guidance in the second paragraph on page 4-5 also specifically states that any changes to EPA's policy to use a 7 percent discount will be reflected in an update to OSWER Directive 9355.3-20. EPA has not updated that directive, and thus use of a 7 percent real discount rate is still the expectation per that directive. Furthermore, while the statement that a differing discount rate can be considered based on a change to the discount rate within OMB Circular A-94 is correct, OMB has not changed from a 7 percent real discount rate (see Paragraph 8(b)(1) of OMB Circular A-94). Updates to discount rate in Appendix C of OMB Circular A-94 are not considered changes to the policy (see second paragraph on Pages 4 and 5 of EPA guidance (USEAP 2000) and related Footnote 3).

LWG also asserts that a differing discount rate should be used to be consistent with financial assurance practices used for these types of sites that use funding from PRPs. As indicated on Page 1-2 of EPA 540-R-00-002, feasibility study cost estimates are not meant for budgeting, allocation, or settlements. EPA may take a different approach for those purposes, such as indicated in Footnote 3 on Page 1-2. However, that will not be reflected in feasibility study cost estimates where the primary purpose is for comparing remedial alternatives during the remedy selection process.

It should be noted that while EPA used a 7 percent real discount rate for presentation of the alternative costs, a sensitivity analysis was performed for varying discount rates and presented in Appendix N of the feasibility study report (USEPA 2016b). This is consistent with the recommendation in the third paragraph on Page 4-5 of EPA 540-R-00-002.

## 2.22.13 Be Flexible in Technology Assignment, Current Conditions, and Site Factors Affecting Cost Estimates

### Comment Summary

Two commenters requested that EPA show flexibility in technology assignment, current conditions, and site factors affecting cost estimates. Commenters state that site conditions may result in design and remedy implementation costs that may be significantly different than the generic cost estimate contained in the feasibility study report and proposed plan.

### **EPA Response**

The sole purpose of the feasibility study is to develop remedial alternatives to be compared to each other in order to select a preferred alternative for presentation in the proposed plan (USEPA 2016c). The technology assignments in the 2016 feasibility study report (USEPA 2016b) are based on current information about the Site. The report makes specific assumptions based on current conditions to develop remedial alternatives that can be compared to each other to inform remedy selection. Costs cannot be derived in the feasibility study unless a technology is selected and evaluated. EPA used several lines of evidence based on site conditions described in the remedial investigation report to determine the appropriate technology to apply to various areas of the Site. It should be noted that all alternatives (other than the “no action” alternative) used the same types of technology assignments (capping, dredging and disposal, in-situ treatment, ENR, etc.). The difference between alternatives was the selection of a RAL for focused COCs and how that affected the extent and locations of the remedy components identified through technology assignment. The purpose of structuring alternatives in this manner was to understand how selection of a RAL affects achievement of the threshold criteria and tradeoffs in the balancing criteria to select a remedy, not to prescriptively assign a technology to a location. That will be performed during remedial design using the decision tree provided in the ROD.

It should be noted that EPA agrees that maintaining flexibility in construction methods through the remedial design phase is an important consideration, particularly for nearshore areas near structures, area with debris, and areas concerning with slope and structural stability issues. The feasibility study uses representative process options and remedial technologies in order to develop and evaluate alternatives according to CERCLA criteria. The ROD includes a flexible decision tree along with general design requirements to guide the assignment of capping and dredging technologies, based on specific characteristics within SMAs. The decision tree will be used during remedial design to define what actions should be taken under different environmental conditions and locations based on the most recent design data. Once the data and river factors are evaluated within the context of the decision tree, a final design for construction can be completed. This design will then dictate the remedial construction. The decision tree is intended to provide clear direction on what actions should be taken under the different environmental conditions.

Therefore, the specific information associated with SMA footprints, dredging depths, estimated volumes of dredged material and cap material, and thickness of caps and/or types of cap layers are assumptions for purposes of developing cost estimates for the remedial alternatives. These assumptions were developed based on the existing data and will be finalized during the remedial design, after design level data to refine the baseline conditions are obtained.

### **2.22.14 Ensure Availability of Suitable Capping Material**

#### **Comment Summary**

One commenter was concerned about the availability of suitable capping materials. The commenter states that EPA’s selected remedy will require a large volume of sand for use in capping and for covering dredge residuals during construction and that the cost and availability of capping material is not adequately assessed.

#### **EPA Response**

Materials and supplies identified as remedy components for the remedial action are conventional (such as sand, rock, diatomaceous earth, quicklime). EPA has initiated discussions with representative commercial borrow sources in the Portland metropolitan area to determine whether they have the ability to provide and transport (using barges where possible) the required volume of capping and

residual management material. EPA confirmed that commercial suppliers could supply the required volumes of materials need for remedy components. EPA assumes commercial sources of capping materials, and that more than one source may be required for volume and/or material quality needs.

### 2.22.15 Modify Transloading Costs

#### Comment Summary

One commenter was concerned about the transloading costs as presented in the cost estimates. The commenter states that important costs associated with constructing a transloading facility are omitted, unreliable, or contrary to EPA's own guidance. The commenter cites specific costs for development, permitting and remediation of the transloading facility.

#### EPA Response

EPA included a transload facility cost to cover potential needs for transload, depending on the mode of transport used. Specific information on the varying possibilities for transload are discussed in Appendix F of the feasibility study report. The feasibility study makes an assumption that the majority of dredged material for disposal is transported by barge, and that the various pre-treatment amendments as well as dewater removal and treatment would occur on water in barges. Thus, the transload requirements are primarily assumed for off-site transload from barge to other modes of transport to the representative disposal facilities. Because the location of transload is indeterminate at this time, EPA used elements of LWG's transload development costs as representative for potential future transload requirements. The Cost Estimate Backup - Cost Source Database (*WRKSHT NO.: CALC-1, Unit Costs for Transload Facility Development*) of Appendix G of 2016 feasibility study report presents how the unit costs for transloading facility was developed. It should be noted that not all costs from Backup Table 24 was used. Only selected unit costs from this backup were utilized in the cost estimate. Green highlighting indicates unit costs that were used in the cost estimate. As noted in the backup, full development unit cost of \$7.5M minus addition of new rail line (~\$3.5 million) was used for transload facility development. The 2016 feasibility study report assumes that trucking would be used to transport material transloaded from barges instead of rail. This approach was discussed with representatives from the assumed disposal facilities (ChemWaste and Roosevelt).

As noted in the comment, "*the total estimated construction cost for the transloading facility is \$28.5M*", is a false assertion. As presented in *Appendix G, Cost Estimate Backup – Previously Developed Costs by Anchor QEA, Table 24*, \$28.5 M is the total estimated cost for "Upland Subtitle D Landfill Disposal". This total estimated cost, apart from Transload Facility Development cost, includes costs for "Materials Handling and Stabilization", "Transportation and Disposal", and "Inspection and Monitoring of Transload Facility."

## 2.23 Paying for Cleanup

### 2.23.1 Ensure the PRPs Pay For Cleanup

#### Comment Summary

A total of 1425 comments were received stating that the PRPs should pay for cleanup. About 60 percent were received as form comments in emails or postcards. The most frequently received of these comments are:

- "Hold polluters accountable for creating a safer Portland Harbor."

- “Entities which have liability for the persistent pollutants in the river sediments must meet their community obligation to conduct a comprehensive and timely cleanup” (or a slight variation).
- “American rivers and streams have been the dumping grounds of polluting industries for decades. I ask that you design and implement a strong cleanup plan for the Willamette/Portland Harbor Superfund Site. Those who have liability for the PCBs, DDT and other pollutants now in river sediments must meet their community obligation to do the right thing and conduct a comprehensive and timely cleanup.”

The remainder of the comments were personal statements. Several named one or more PRPs and a common theme was that the companies that had profited from causing the contamination should be made to pay for it. Many people spoke of PRP payment as a deterrent to future contamination.

Representative comments include:

- “We need to hold the companies who made the mess responsible, and hold them accountable for the cleanup, even if the cost is significant. They have made money from the river which belongs to everyone! Now they need to step up to restore it.”
- “Polluters like Chevron, Exxon, ExxonMobil, Northwest Natural, and Schnitzer Steel made our river toxic. Now, they should have to clean it up.”
- “Responsible parties include some of the biggest industries in Oregon and the world. While some industries complain this will hurt the economy, EcoNorthwest did a study, which determined that every dollar spent on the cleanup of the river generates more than one dollar of economic activity.”
- “Make the polluters pay for their dumping. Don't let them off the hook. Do the people right and not the corporations who polluted the river.”
- “If businesses who/which deposited the pollution are not required to clean it up, businesses in the future will be incentivized to engage in the same irresponsible behavior. Why act responsibly when you can save money by dumping your mess, collecting huge profits, spending the profits, and then declaring bankruptcy before you are required to pay the true costs of your irresponsible methods? No, the Native Americans are right; the polluters need to clean it all (or mostly all) up NOW. If some of the polluters cannot be held responsible due to bankruptcies or other forms of shunting responsibility, then, as usual, it's up to the taxpayers to pick up the slack and fund that portion of the clean-up. It's the only responsible thing to do, no matter how costly.....”
- “I've been a citizen of Portland for 31 years. It appears that most of the contaminants of concern are the type of contaminants that seem to be likely produced by businesses, and yet I'm hearing that the public ratepayers would end up paying some fraction of the cleanup cost. I would guess that you're getting pressure from the business owning PRPs to have the public (in the form of Vera Environmental Services) share this cost for various reasons related to outfalls in the river. As a member of the public I would push back against that and ask that the great majority of the cost, preferably all of it, be assigned to the types of businesses that create the contaminants of concern.”
- “Money can't reverse the damage to wildlife but serves as a punishment/deterrent for irresponsible behavior. Entities with liability for the pollution must be held accountable and pay

for a comprehensive cleanup that will protect the health of our communities, our environment, and our wildlife.”

### **EPA Response**

The purpose of the proposed plan (USEPA 2016c) was to present EPA’s evaluation of remedial alternatives for the in-river portion of the Portland Harbor Site. As required by CERCLA, EPA sought public comment on that evaluation and supporting information to consider in making its final remedy decision. Public comment was not sought on issues of funding the cleanup or liability for paying for cleanup and will not be addressed in any detail in this responsiveness summary. Likewise, the ROD provides the basis for and description of the final selected remedy for the in-river portion of the Portland Harbor Site but does not address issues of liability or enforcement of how the remedy will be implemented. EPA agrees that the parties responsible under CERCLA should pay for the cleanup, consistent with EPA’s long-standing “polluter pays” policy. Limited appropriated funds for cleanups are typically used for sites where there are no viable responsible parties. Under CERCLA, EPA searches for parties legally responsible for the contamination and seeks to hold those parties accountable for the costs of investigations and cleanups, by requiring them to perform or fund the necessary investigations and remediation. EPA will follow this approach for the Portland Harbor Site.

EPA continues to support a comprehensive allocation of liability by the PRPs at the Site to facilitate settlements that implement the selected cleanup actions.

## **2.23.2 Require Performance Bonding**

### **Comment Summary**

Twelve comments were received that addressed the issue of performance bonding. Most were individual, personal comments. All of the comments stated that performance bonds were necessary and a few believed they should be required in the ROD. One person suggested a storage tax/fee. The Portland Harbor Community Advisory Group wrote that they wanted bonding assurance that met Superfund guidance.

Representative comments include:

- “Polluters must pay for the cleanup not tax payers PRP need to pay and post-performance bonds.”
- “In order to provide the certainty the public deserves, EPA should require some form of insurance or performance bonds to cover the cost of additional remedial action if the adopted plan does not lead to the anticipated or desired results.”
- “Performance bonds must be required in the ROD. MNR and capping are proposed in all options, and increase the likelihood of recontamination at some level. If they are the main remediation method relied on as suggested in EPA recommendation, there is a chance of recontamination at a higher level. Therefore, the ROD needs to include the requirement of Performance Bonds and state that any cleanup activity resulting from recontamination must be fully funded by polluters rather than the community.”
- “Compliance with the Record of Decision needs to be formally drafted into Record of Decision. The resistance to accepting responsibility for harming the community highlights a need for performance bonds. Funding needs to be guaranteed beyond a one and done perspective to ensure completion of environmental remediation and successful restoration.”

- “Assurance bonds/or insurance should be required to pay for any continued and recontamination of the river or need to redo remedies proven to not be meeting goals or through accident. A storage tax/fee should be applied to the PRPs until the toxic materials are gone from the river, adjusted to the level of toxic material in the sediment, with proceeds to go to OR school funds.”
- “Performance bonds are part of CERCLA. We want EPA to request legally binding commitment performance bonds from PRPs - since EPA has “no” funds, we want to make sure PRPs have funding designated to future “uncertainties.” Funding should not solely be on General Fund tax payees.”
- “The CAG wants EPA to certify that “bond assurance” meet the requirements of *Guidance on Financial Assurance in Superfund Agreements* as found in [www.epa.gov/sites/production/files/2015-04/documents/fa-guide-2015.pdf](http://www.epa.gov/sites/production/files/2015-04/documents/fa-guide-2015.pdf).”

### EPA Response

The purpose of the proposed plan (USEPA 2016c) was to present the remedial alternatives evaluated for the in-river portion of the Site. As required by CERCLA, EPA sought public comment on the evaluation and supporting information to consider in making its final remedy decision. Public comment was not sought on issues of funding the cleanup, including the requirement for performance bonds, or liability for paying for cleanup and will not be addressed in any detail in this responsiveness summary. Likewise, the ROD provides the basis for and description of the final selected remedy for the in-river portion of the Portland Harbor Site but does not address issues of liability or enforcement of how the remedy will be implemented. EPA agrees that the parties responsible under CERCLA should pay for the cleanup, consistent with EPA’s long-standing “polluter pays” policy. Limited appropriated funds for cleanups are typically used for sites where there are no viable responsible parties. Under CERCLA, EPA searches for parties legally responsible for the contamination and seeks to hold those parties accountable for the costs of investigations and cleanups, by requiring them to perform or fund the necessary investigations and remediation. EPA will follow this approach for the Portland Harbor Site. Typically, it is EPA policy and practice to require financial assurance from parties that perform cleanup work. EPA continues to support that a comprehensive allocation of liability by the PRPs at the Site be accomplished to resolve all claims EPA may have against the PRPs and they may have between each other.

## 2.24 Flexibility in Implementing Cleanup

### 2.24.1 Address the Most Contaminated Areas First

#### Comment Summary

Commenters had divided opinions on whether or not the Site should be addressed as a whole or whether cleanups should be initially targeted at the most contaminated areas. About 75 percent expressed a desire for EPA to be flexible in implementation of the cleanup. Flexibility was often tied to starting with the most contaminated portions of the river first, taking into account changes in the river and site-specifics, and trying lower cost solutions first. Very often, but not always, having separate operable units (OUs) was specified.

Those supporting addressing the most contaminated areas first, possibly through separate OUs, included residents, PRPs, and the City of Portland. Representative comments are:

- “The agency should consider a revision to break up the plan into multiple parallel projects, in order to permit accelerated mitigation on separate elements. If the Port of Portland can address the complex of questions relating to the Swan Island area, lagoon, riparian zone or upland- then

accept the concept of an “operable unit”. If the concept of such units is accepted and activated by EPA, there can progress on parallel units, without every element of the plan being delayed by dependence on every other problem or dispute between interested parties at risk.”

- “Allow responsible parties to pursue equally protective remedies that get cleanup moving forward soon. I believe the cleanup of the Willamette River offers opportunities for the future of our region. Let’s move forward to a responsible solution.”
- “Contamination and risks are not uniform throughout the Portland Harbor. Flexibility would allow the cleanup to take into account changes in the river and site-specific risks in a more cost-effective manner.”

Requests supporting the use of OUs were longer and generally requested that the Site be address by OUs. This would allow EPA to work with subsets of the large group of PRPs and work on areas that are already well-defined or of lower risk.

Those against the concept of separate OUs seemed to fear that the PRPs would use it to their advantage to negotiate less comprehensive cleanups and that complexities relating to paperwork and regulations would increase.

Representative comments against OUs include:

- “The idea of splitting the Superfund site into separate and independent operating units suggests the possibility that PRP’s may apply political pressure to compromise the integrity of the cleanup. Under the oversight and jurisdiction of EPA, multiple sites can be remediated concurrently with all parties observing the same rules of conduct. Cleanup requires a level playing field for all”
- “I oppose the use of separate operable units during this restoration. I believe that restoration can take place on differing timelines in different areas without the complexities and difficulties that the creation of separate operable units will bring to the process.”
- We "do not want" to have separate paperwork, analysis, studies, proposed plans or records of decision on this clean up!!”

### **EPA Response**

EPA agrees that maintaining flexibility in construction methods through the remedial design phase is an important consideration. Additionally, EPA agrees that active cleanup technology assignments will be evaluated during remedial design based on new data and area-specific conditions and land uses and other requirements specified in the ROD.

EPA recognizes the desire for the use of OUs or breaking the Site into pieces for remedy implementation at such a large and complex site. There may be advantages to using OUs or other mechanisms for addressing smaller geographical areas for remedy implementation at such a large and complex site. Given the size of the Site, work window constraints, and other considerations, remedial action will be implemented in phases given that collection and evaluation of area-specific information would be conducted during remedial design.

Formal designation of OUs is not critical or necessary to devise a plan how to address the highest risk areas first and sequence cleanup to minimize recontamination of cleaned up areas. EPA anticipates that

much information will be learned in the post-ROD remedial design that will help EPA to determine the most effective approach to sequencing and other aspects of how the remedial action will be implemented. EPA will generally be focusing on having the highest concentration areas addressed first to reduce risk sooner and minimize recontamination to areas cleaned up later.

The entire Site cannot be addressed at one time as a practical matter. However, no matter how the cleanup is phased, implementation of the remedy will not affect the overall integrity and comprehensiveness of the cleanup. We also recognize that some members of the public oppose the use of OUs or other such divisions and EPA wants to assure the public that all viewpoints are being considered; and, if such a decision is later considered, EPA will continue to have public outreach over the design and remedy implementation phases for public participation and input.

EPA has been involved in the development of focused investigations and remedial actions at the early action sites, including Terminal 4, Gasco and Siltronic, Arkema, and RM 11 East, and took these into consideration in development of the remedy. Prioritizing further remedial action at these sites will be considered during remedial design.

### 2.24.2 Consider Assorted Flexibility Requests

#### Comment Summary

Requests for flexibility came from the general public, businesses (Arco/BP, City of Portland, ESCO, Exxon Mobile, Geosyntec, NW Natural, Port of Portland, RM 11 East Group, Schnitzer, Siltronic, Swan Island Group, Calbag Metals), and the USACE.

Specific requests include:

- Be flexible in selection of remedial technology.
- Flexibility is needed at a specific location (Swan Island, Gasco, or RM 11E).
- Site-specific toxicity testing is needed to verify model outcomes and design the final remedial action.
- EPA should account for site-specific conditions to ensure early actions are not disturbed or destroyed.
- Modify the technology assignment flowcharts to make clear that flexibility is anticipated.
- EPA should be flexible to adapt to new data and the ROD should explain how the remedy will be implemented when there is a change in structure configuration (dock being removed).
- Use adaptive management principles by selecting higher RALs (Alternative B) so that site cleanup can focus on areas of highest potential risk and establish OUs at those areas. This would enable EPA to refine SMA boundaries, evaluate the effectiveness of remedial approaches and technologies, reduce uncertainties of natural recovery, adjust or refine by ongoing monitoring-adaptive management.

#### EPA Response

EPA acknowledges that technology assignments will be evaluated based on new data and observations collected during remedial design. The ROD contains a revised, simplified decision tree for selection of remedial technologies during the remedial design process. Compared to the decision trees provided in

the feasibility study report (USEPA 2016b), the ROD decision tree is less prescriptive and demonstrates flexibility for selection of remedial technologies with the assumption that a detailed evaluation of area-specific conditions would be conducted during remedial design. Remedial design investigations will consider prioritization of areas posing highest risk, sequencing, and other aspects of how the remedial action will be implemented. Avoiding disturbance or recontamination of early action areas will be an important part of the remedial design evaluations. Construction of permanent caps will be carefully scheduled to avoid recontamination from upland or in-river work.

EPA is aware that area-specific conditions must be considered during remedial design, including the presence of active docks or other structures, caps and other remedial activities already in place, river uses, and many other considerations. Additional guidelines are provided in the ROD to convey this information.

The feasibility study report states in several places that additional data will be collected during remedial design to assist in refining the remedy beyond the feasibility study-level of analysis and the ROD reflects this as well. EPA intends to evaluate additional data during remedial design to refine the following: delineation of contamination, selection and design of remedial technologies and construction methods, projections of natural recovery, treatment and disposal requirements, measures for aquatic and listed species protection, and compensatory mitigation requirements, to name a few.

EPA does not agree with the use of adaptive management as a way to postpone remedial action implementation or use less restrictive RALs that necessitate greater reliance on natural recovery. The extensive evaluations already conducted, along with the successful use of remedial technologies at other sites, have informed EPA's selected remedy as described in the ROD. Further refinements in the approach will be evaluated in five-year reviews and memorialized in appropriate decision documents.

## 2.25 Early Action Sites

### 2.25.1 Coordinate Cleanup with Work at Early Action Sites

#### Comment Summary

Five commenters expressed concerns regarding work still to be done at the Early Action sites to prevent recontamination of Portland Harbor.

Representative comments include:

- "EPA must use its enforcement authority to force early-action clean-up sites that put the Portland Harbor at risk of re-contamination once in-river clean-up begins."
- "We want a commitment for increased shoreline remedial action. Especially at the Arkema site. We want "more" than management we want control of upland source contamination! We want a legally binding source cleanup form or (DEQ) uplands; we need dates of completion!"
- "More extensive cleanup is called for in river mile 11. The Arkema site and Gasco, as these sites are heavily polluted with persistent toxins which won't be cleaned up with MNR."
- "Re-examine completeness of Early Actions or Hotspot Activities of DEQ. Some cleanup actions have already occurred or were initiated at several areas within the Portland Harbor Superfund Site:

- BP Arco Bulk Terminal. A sediment removal action of the nearshore area adjacent to the BP Arco Bulk Terminal was conducted in 2007-2008 under DEQ oversight. Approximately 12,300 cubic yards of petroleum-contaminated soil and sediment were removed and disposed off site at a permitted facility. The excavated area was backfilled with clean fill and a steel sheet-pile seawall was installed along the entire river bank of the BP Arco Bulk Terminal property. When the remedial design sampling is produced, it needs to include all shoreline; not just the previously examined 20,000 lineal yards but needs to address all 30,000 lineal yards to ensure all contamination is included.
- River Mile 11E Project Area. As the site containing one of the highest levels of PCB's this site should be thoroughly and completely excavated and the contents removed, place on barges and carried to Roosevelt Facility in Goldendale Washington. This and Swan Island has potential for habitat restoration and future human use.
- NW Natural. Please remove all of the tar body and the associated chemicals at the GASCO site and do not just cap it. While it is one of the most devastating sites I believe NW Natural is a needed and important entity to the Portland community and deserves support. EPA, other PRP's and citizens should make every effort to financially support its cleanup for the sake of the citizens, the river and the future. If it takes supporting grants, fundraisers and other activities, the GASCO site should be completely cleaned up but given support so the financial burden is not so overwhelming that it jeopardizes its valuable contribution to Portland.
- Arkema. Arkema is and always has been another devastating site that needs EPA's attention. While it has made little contribution to the citizens of Portland's welfare; the Arkema desperately needs all the effort, time and money that both DEQ and EPA can give it. If left unchecked, it will continue to overwhelm the health of the river for years. U.S. Moorings. Please just test the efficacy of the work that has been started here. Please complete the necessary actions to ensure the sources are controlled completely.
- Triangle Park. Please certify that the University of Portland completes its removal action and other procedures to properly clean up the site to protect human health and the students to be using it in the future. The four main components to the completed removal action included ICs, groundwater monitoring, excavation, and capping.
- Gasco. NW Natural, Siltronic Corporation and EPA signed an AOC for a Removal Action in September 2009. NW Natural and Siltronic are conducting site characterization and design evaluations for the area offshore of their two facilities. They have also agreed to perform further characterization, studies, analysis and preliminary design for the final remedy at the Gasco Sediment site. The studies and other work under the agreement were incorporated into the Portland Harbor remedial investigation/feasibility study. Please confirm that the site excavations and removal of contamination are complete and not just capped or covered up."

## EPA Response

During the remedial investigation and feasibility study, EPA entered into agreements with Arkema Inc., NW Natural and Siltronic, Port of Portland, and a group of companies related to RM 11E to undertake early actions in the river adjacent to their facilities. Notwithstanding those agreements (some of which are still in place and others are not) all of the Early Action areas investigated and/or cleaned up under those agreements are included in the feasibility study and are included in the remedy for the Portland Harbor Site that EPA has selected. All of those “Early Action” areas have highly concentrated contamination and need to be remediated. EPA is committed to addressing these areas as early as feasible in the cleanup of the Site. Addressing contamination at the Early Action area as soon as feasible is critical to a successful cleanup of Portland Harbor in order to reduce risks at the Site and prevent recontamination of downstream and nearby areas.

Several commenters expressed concern with the status of and plans for cleanup at Arkema, Gasco, and RM 11E. A significant amount of investigation has occurred; however, with the exception of Gasco, and Terminal 4, no cleanup has taken place as of yet at these Early Action sites. All three areas will be addressed as part of the Portland Harbor Site cleanup. Approximately 15,300 cubic yards of a tar-like material and tar-like contaminated sediment were dredged in 2005 from the river bank and nearshore area adjacent to the Gasco facility and an organoclay mat and sand cap was installed over the dredged area. Dredging and bank work took place at the Terminal 4 site as well.

Under the EPA selected remedy, the following is anticipated at these locations:

- Gasco. Future maintenance dredging adjacent to the facility dock as well as areas in the Federal Navigation Channel. Between the Federal Navigation Channel and the shoreline there is a mix of dredging (including dredging in the footprint of the 2005 tar removal), capping, dredge with cap and a small area of MNR. The remedy for the Gasco river bank will be integrated into the adjacent in-river work.
- Arkema. Future maintenance dredging in the downstream area and immediately downstream of the facility dock (unless it is removed) as well as a small area in the Federal Navigation Channel. Between the Federal Navigation Channel and the shoreline there is a mix of dredging, capping, dredge with cap. The remedy for the Arkema river bank will be integrated into the adjacent in-river work
- RM 11E. Future maintenance dredging adjacent to the project area as well as areas in the Federal Navigation Channel. Between the Federal Navigation Channel and the shoreline there are areas of cap and dredge.

Another comment mentioned a sediment removal action conducted in 2007-2008 at the BP Arco Bulk Terminal where the excavated area was backfilled with clean fill and a steel sheet-pile seawall was installed along the entire river bank of the BP Arco Bulk Terminal property. The request for remedial design sampling on additional shoreline is noted. Under the selected remedy, a combination of capping and dredging is anticipated in the area of the dock located offshore of the BP Arco Bulk Terminal property.

EPA also oversaw upland cleanup activities at the University of Portland’s property called Triangle Park as part of a Prospective Purchaser Agreement. The University performed cleanup of that property in 2013 and which is currently undergoing monitoring. EPA oversaw source control studies conducted by

the USACE at the US Moorings site. Based on those studies, the USACE addressed soils deemed erodible into the river. Based on current information, no further upland source control is needed. However, cleanup of sediment adjacent to both Triangle Park and US Moorings is a part of the Portland Harbor ROD.

## 2.26 Clean Up of Specific Areas of the Waterway

### 2.26.1 Address Outstanding Issues Sediment Management Areas

#### Comment Summary

Comments were received from five commenters relating to specific issues with the SMAs as presented in the feasibility study report and/or proposed plan. Those comments are:

- PTW was used inappropriately in development of the SMAs.
- Near-shore sediment sample data should not be separated from navigation channel sediment sample data to develop PTW threshold and RAL contours. This results in the inappropriate delineation of SMA boundaries and consequently calls into question EPA's estimates of dredge volumes, areas to be capped, and costs.
- The SMA used for Alternative I near Kinder Morgan Linnton Terminal is based on a single non-detect for PCBs that happens to be greater than the RAL for PCBs at Alternative I. EPA does not address how non-detects are used in the development of SMAs.
- Sediment data does not support the designation of an SMA offshore of the Shore Terminals facility.
  - DDx. The basis for a DDx-delineated SMA offshore of the facility is unclear since none of the 38 shallow sediment samples collected offshore for the facility contain DDx concentrations that exceed the RAO 5 PRG. DDx should not be listed as a focus COC for sediment offshore of the facility (RM 5W).
  - TPAHs. Only two tPAH samples contained concentrations that exceed the corresponding PRG for RAO 5 and one was taken 19 years ago. The proposed plan should be modified to exclude the SMA offshore of the facility within the RM 5W SDU because TPAH and DDx concentrations in shallow sediment in the SMA do not meet EPA criterion for defining an SMA (greater than 10x the RAO5 PRG) and the SMA is based on widely dispersed and outdated data.
- The basis for SMA Extent in SDU7W is incorrect. There is an unwarranted increase of the sediment remedy area off-shore of Siltronic, driven by non-focus COCs. This area can be minimized while achieving the intended risk reduction by implementing RALs that are more appropriate for non-focus COCs in SDU7W, or by extending SDU6W to include the entire Siltronic shoreline. EPA should not apply Alternative F RALs for non-focus COCs in SDU7W arbitrarily assigning active remedy thresholds that result in estimated post-construction concentrations that are inconsistent with the other areas of the site.
- EPA's proposed SMA area adjacent to the Time Oil facility is unnecessary, because EPA's remedial action objective is already met in all relevant exposure areas. Based on feasibility study report Figure 3.4-10, we understand that EPA has defined this SMA through the Alternative E RALs for 1,2,3,7,8-PeCDD.

## EPA Response

Responses to the comments listed above are:

- The values used for PTW as well as the recommendation that EPA should review FMC's food web model report are addressed in the food web model response (Section 2.11.1 of this responsiveness summary).
- The use of additional samples is addressed in the SWAC response (Section 2.7 of this responsiveness summary).
- The SMA near the Kinder Morgan Linnton Terminal is based on the RAL contours from both PCB and PAH samples. While EPA acknowledges that there are non-detects driving the PCB RAL contour footprints in this area, the PAHs footprints for Alternative F and G consist of detected samples and is the predominant contaminant in the area. The sample data presented in the on feasibility study report (USEPA 2016b) was used to best represent the possible area of remediation for estimates of volumes and costs. However, further evaluation will take place during the remedial design to determine if higher levels of contamination are present or not.
- The commenter seems to confuse how SMAs and RALs are defined in the feasibility study report and proposed plan (USEPA 2016c). For each of the focus COCs, a footprint is defining the area where sediment concentrations are above the RAL for each alternative as shown in the feasibility study report (USEPA 2016b) Figures 3.4-7 to 3.4-12. The SMA footprints for each alternative are a spatial addition of each of the COC RAL contour footprints. There is no single SMA defined by RAO 5 PRG and all focus COCs are taken into account when creating SMAs. DDX and PAHs have been shown to be predominant COCs in RM 5W but that does not mean they are the only COCs with higher concentrations outside of the property in question. The primary driver outside of the Shore Terminals facility does seem to be PAHs, of which there are many samples with higher concentrations than the associated RALs for Alternative D, E, F, and G as seen in on feasibility study report Figure 1.2-9a.
- The dispersion and sample dates have been addressed in Sections 2.7 and 2.10 of this responsiveness summary. Further, additional sampling efforts and local evaluation of contamination will take place during the remedial design phase.
- The commenter does not state what the specific "non-focus" COCs are that are driving the asserted increased SMA footprint. The commenter may be referencing feasibility study report Figure 4.1-2 which is incorrectly labeled as showing the focus COCs when in fact it shows the predominant COCs in each SDU as described in Section 4.1.1 of the feasibility study report. The focus COCs are described in Section 3.4.1.1 and all of the focus COCs in this section are used in defining the SMA extent across the entire Site, making it consistent across the Site and not arbitrarily assigned at this area only. The SDUs are defined by the rolling river mile average concentrations of the focused COCs identified in Section 3 of the feasibility study report and are not defined by property boundaries. However, further evaluation at a local level will take place during the remedial design process and actual contamination extent will be identified then.
- The commenter is correct that the small location in question is primarily driven by the 1,2,3,7,8-PeCDD sediment samples. Further evaluation will be done during the remedial design phase in order to determine the actual extent of the contamination.

## 2.26.2 Correct Contaminant Characterization of the River Banks

### Comment Summary

Multiple comments were received from commenters regarding the contaminant characterization of the river bank. They include:

- Figure 19e of the proposed plan delineates shoreline areas around the western and northern perimeters of Swan Island as having known contamination of the river banks. We are not aware of any sampling events producing data showing that the river banks are contaminated in these locations. In fact, much of the delineated shoreline consists of sheet-pile bulkheads that are obviously not available for sampling or remedial action.
- Database included in Appendix A of the feasibility study report is flawed. The data source for river bank contamination is useless for understanding EPA's rationale because the ECSI database is overly broad in content to be used for the purpose of characterizing river banks. Similarly, Appendix A does not include the river bank data compilation. The database offers little to no value for assessing river banks because it is incomplete and has not been subject to any quality assurance review. Errors in the database in Appendix A and data has not been checked for accuracy. Also, Appendix A appears to be a haphazard compilation of various data (or little care was taken to compile the data base), some of which has nothing to do with river banks. A review of the "matrix code" column finds most entries are blank, and many entries are data that are not from river bank soils. If EPA is using the data in Appendix A to make decisions, the data should be subjected to all of the usability criteria attendant to any other data on which EPA relies. Data base is also missing critical information inputs such as sample coordinates, incorrect data, incomplete data set (e.g., middle or southern shoreline.)
- EPA must characterize a site prior to selecting a remedy. At a minimum, characterization includes field investigations and a baseline risk assessment. These studies provide the information necessary to assess risks to human health and the environment and to support development, evaluation, and selection of appropriate response alternatives. The NCP requires that remedies are selected based on consideration of nine criteria, critically including: (1) reduction of toxicity, mobility, or volume through treatment, and (2) overall protection of human health and the environment. River banks were excluded from the remedial investigation; therefore, EPA could not and did not follow this process. EPA needs an approach for river banks that complies with NCP.
- The ROD should identify all contaminated river banks that are identified in DEQ's 2016 Portland Harbor Summary Report. There are concerns that the proposed plan includes remediation of over 19,000 feet of river bank, but the remedial investigation and baseline risk assessments do not provide the necessary information for understanding the nature and extent of the current contamination in the river bank soil. EPA should review Oregon DEQ's most recent Upland Source Control Summary Report where DEQ has identified the presence of uncontrolled river bank contamination and include these river banks in the maps and discussion (such as Crawford Street Corporation cleanup).
- EPA does not have a complete understanding of existing river bank data or prior source control efforts overseen by DEQ. Properties identified in the remedial investigation with river bank contamination do not match the properties presented in the feasibility study report and proposed plan. Properties identified as having insufficient data to make a determination of a river bank

erosion pathway in the remedial investigation report are now listed as properties with “known contaminated river banks” requiring cleanup in the draft feasibility study report and proposed plan, with no explanation. Specific examples are SSI’s Burgard Yard, which includes 3,500 data entries attributed to another site at RM 9W, Gunderson’s property, and former Mar Com (South) property.

- EPA has misconstrued DEQ’s findings identified in the ECSI database. DEQ’s findings were not intended to take into account the physical characteristics of the river banks, the locations where contamination was identified along the bank, or the specific contaminants or concentrations detected. EPA’s identification of contaminated river banks is incorrect and does not always agree with in-river impacts. Additionally, EPA’s characterization of river bank soil contradicts characterization in DEQ’s *Upland Source Control Summary Report* (DEQ 2016). EPA has misconstrued a substantial volume of data compiled under DEQ oversight.
- River banks are arbitrarily identified without addressing data, most recent cleanup actions, or delineating where cleanup actions actually begin and end. EPA does not clearly state what it means by including river banks, ambiguously stating that they will be included if “it is determined that it should be conducted in conjunction with the in-river actions.”
- River banks are included without clear delineation or sampling evidence. Inclusion of the river banks in the feasibility study report was last-minute and not evaluated in the remedial investigation. Remedial alternatives for river banks were not evaluated in the feasibility study report. The river bank remedy would likely require the removal and reconstruction of buildings, dock structures, underground utilities, railroad lines, and existing groundwater source control measures.
- PCBs are listed in EPA’s feasibility study report as a river bank contaminant at a large portion of SDU 7W, but have only been detected in a small number of samples below the applicable screening levels (with one exception, one sample slightly exceeded a conservative bioaccumulative screening level value [ERM 2008; Attachment 2]). Yet, this arbitrary delineation is then carried forward into the proposed plan.
- EPA has no basis for determining river bank soil risks and uses an oversimplified approach by comparing chemical concentration in soil to sediment PRGs. This is inconsistent with EPA’s guidance which requires a baseline risk assessment. The PRGs used by EPA for evaluation of river bank soil were established for sediment and potential receptor/exposure pathway relationship for river bank soil are fundamentally different. EPA only identifies two remedial action alternatives: excavate or no action. However, capping and armoring will likely be the preferred alternative for some river banks.
- The facility river bank may not be contaminated, the river bank pathway is incomplete, DEQ has designated the river bank as a low priority.

### **EPA Response**

DEQ determined that two areas of river bank in OU1 of Vigor Marine Ship Repair Yard (formerly known as Portland Shipyard) require source control measures and are a medium priority for source control. The two areas total approximately 1,100 linear feet (DEQ 2016).

The data provided in Appendix A of the feasibility study report (USEPA 2016b) was not used to make design level decisions regarding river bank contamination (see disclaimer included with Appendix A). River bank contamination was characterized by DEQ as part of upland source control and will be further evaluated with adjacent in water work in each SMA per the decision tree in the ROD. The decision tree provides a framework for designing the remedy at specific properties and will utilize new data collected during the decision phase.

Like the upland sources, the river banks are within the geographical boundaries of the Portland Harbor Site and river banks are appropriately included in the selected remedy. During the remedial design phase, each river bank area will be further evaluated to determine if remedial action is needed to comply with the ROD; if additional action is needed, a remedial design will be completed for the facilities' river bank.

The data and information regarding the extent of river bank contamination was provided by DEQ and reviewed by EPA should be representative of conditions described in the 2016 Portland Harbor Summary Report. In response to the City of Portland's comment on the Crawford Street Corporation facility, the Upland Source Control Summary Report (DEQ 2016) described the potential for recontamination as low. Therefore, the facility was not included on Figure 6. But the source control decision for the facility is anticipated to be final in 2018 and river bank soil may need to be addressed. Non-contiguous river banks and SMA will be addressed by implementing SCM on upland river banks before implementing in-river remedies. The final river bank contaminant delineation and the need for an action to address river bank soil will be evaluated during remedial design. The river bank data provided by DEQ and in the administrative record is the most recent data. Additional characterization or monitoring data will be used to make decisions on remedial decision for river banks.

Regarding the comment about data for specific sites (such as Burgard Yard), the river bank data were provided by DEQ. Property-specific river bank data will be collected during pre-design monitoring and will be used to determine the action at each property. Concerns in the final six bullets are addressed in LWG Dispute Issues 1d and 1q (Appendix A of this document).

### 2.26.3 Clearly Identify the River Bank Remedy

#### Comment Summary

Comments were received from four commenters regarding difficulties with the identification of the remedy for river banks. Those comments are:

- In the figures associated with the proposed plan, the extent of contaminated river bank does not change regardless of the SMA, which gives the impression that the river banks require cleanup for each alternative (Figures 11a-g (USEPA 2016)). However, EPA has also assumed that river bank cleanup is associated with contiguous SMAs, such that cleanup would only occur in river banks that are adjacent to an SMA (Table D2.b). To correct these discrepancies, the depiction of contaminated river banks for each alternative should be consistent with EPA's actual approach defined by that alternative.
- Request that EPA include the basic framework for river bank remedy alternatives evaluation in the ROD. EPA should assess the presence of contamination and stability of river banks; develop remedy alternatives evaluation that acknowledges site-specific constraints. The feasibility study report and proposed plan did not provide a remedy evaluation process for river bank soil.

- The proposed plan is also inconsistent in its treatment of river banks. On the one hand, the proposed plan states that “technology assignments for SMAs adjacent to identified contaminated river banks are extended to include those river banks. Where SMAs are projected onto the river bank, removal followed by capping is the assigned remedial technology.” However, EPA’s technology decision trees as applied to river banks are inconsistent with the above statement because they appear to require active remediation, regardless of the presence of adjacent sediment SMAs, when PTW is present in the river banks. Specifically, the decision tree for contaminated river banks (Figure 10d in the proposed plan) appears to indicate that if PTW is present in the river banks (even if the river bank is not adjacent to an SMA), river banks will be excavated and then covered with a significantly augmented reactive cap. EPA’s decision tree appears to associate PTW with river banks. This is inconsistent with the proposed plan and 2016 feasibility study report, which identify PTW only in sediments. EPA should therefore correct the decision tree for contaminated river banks in the ROD and remove PTW from the river bank decision tree altogether.
- Technology assignments are confusing, vague, and in some cases, contrary to the text of the proposed plan and feasibility study report. Armored portions of shoreline should not be included as contaminated river bank; unclear if river banks with contaminants not listed as RALs will require remediation; river bank technology flow chart designations are inconsistent with technology assignments with shallow sediment areas; technology assignment flow chart for river bank soil does not address highly toxic PTW; EPA’s river bank technology assignment flow chart does not distinguish between areas where groundwater may be seeping out of the river bank; EPA has not indicated the depth of contaminated soil that would need to be excavated from contaminated river banks or the slope needed; EPA’s river bank flow chart does not indicate that beach mix is required in the capped areas prone to erosive forces; technology assignments for riverbeds are inapplicable to heavily armored portions of the shoreline.
- As recently as February of this year, EPA confirmed this long-standing arrangement not to include river banks as part of the Portland Harbor Study Area in the recent remedial investigation report (USEPA 2016a). At that time, EPA noted that some river banks could be a source of contamination to the Study Area or Site, but stated that “[t]he occurrence and relative importance of river bank contamination is not well characterized for all parts of the study area, but is a focus of DEQ’s source control investigations” EPA, remedial investigation report, Section 4.3.4.
- The boundary between the shallow habitat zone and the river bank zone needs to be defined so that a baseline and supplemental design investigation for sediment and the river bank can be defined; definition of the zones would facilitate a remedy, if needed. The upper boundary of the river bank needs to be defined as well.
- The design criteria for restoring the river bank slopes is confusing and will lead to significant misunderstanding by the public and responsible parties during the remedial design. The ROD should not specify design criteria, such as slopes, based solely on potential habitat improvements recommendations from National Oceanic and Atmospheric Administration. It is unclear if EPA is accepting the recommend slope criteria for habitat. Maintaining existing infrastructure should be the priority over ideal habitat for slope. ROD should define performance criteria for river banks.

## EPA Response

Recent remedial actions with on-going performance monitoring were not described in the proposed plan (USEPA 2016c) on a site-by-site basis. DEQ's upland SCE information was used to identify river banks with known contamination. If performance monitoring concludes that the remedial action met the requirements of the ROD, EPA may not require further action to be taken to address the river bank.

EPA identified RAO 8, Migration of Contaminated Groundwater, for upland groundwater source control. Groundwater and river bank soil are being treated similarly, as described in the proposed plan; ongoing source control efforts for groundwater and river bank soil will provide additional risk and recontamination reductions.

EPA has included in the ROD an updated decision tree that indicates the flexibility to assess additional data during the design phase to select the appropriate remedial technology to address river bank contamination.

The ROD includes the flexibility for the remedial design to evaluate and select the appropriate remedial technologies. The remedial design will need to address site-specific factors such as highly toxic PTW, depth of excavation, on-site structures, site operations, and other site-specific features.

DEQ identified the extent of river bank contamination, which was presented in the feasibility study report (USEPA 2016b). The site-specific remedial design investigations will delineate the extent of contaminated river banks and physical features, which could impact the selected remedial technology.

Regarding habitat, the boundary between the shallow habitat zone and the river bank and other site-specific features will be evaluated in remedial design in consultation with the Services. The feasibility study made some assumptions regarding river bank slopes (using National Oceanic and Atmospheric Administration criteria), but the river bank slope will be evaluated during remedial design phase and reviewed by EPA, DEQ and will account for services such as overwater fueling to ensure the remedy does not prevent continuation of current services.

For additional information on EPA's approach to river banks, see Dispute Responses LWG 1d or 1q (Appendix A of this document).

### 2.26.4 Address River Bank PRG or RAO Comments

#### Comment Summary

Seven comments were received from six commenters regarding PRGs or RAOs associated with the river bank. Those comments are:

- Contaminated river banks are not always contiguous to an area of active remediation, so integrated cleanup of the in-river area and river bank will not occur (i.e., the feasibility study report states on page 4-7 "Contaminated beach areas under RAO 1 are assumed to only be addressed in areas adjacent to SMAs for each alternative"). Please discuss in the ROD how source control will be addressed at these non-contiguous river bank areas to protect the investment being made to clean up the Site.
- Need a decision node for the flow charts that ask if river bank contamination is being managed under state or other regulatory framework (in which this doesn't apply).
- PTW - NRC/NAPL is not applicable to river banks.

- RALs in adjacent sediment should not be applied to river banks. RALS are based on sediment PRGs and are only relevant to in-river pathways, not river banks.
- The PRGs used by EPA for evaluation of river bank soil were established for sediment. River bank soil is not sediment. The potential receptor/exposure pathway relationships for river bank soil are fundamentally different than those for river sediment.
- EPA should not set river bank soil PRGs since they are not based on risk assessments or available data; without risk assessment, EPA does not know the risk river banks pose. Or the recreational beach exposure scenario overestimates exposure and the PRG for river bank soil should be eliminated.
- RAO 9 is not appropriate or a valid measurement of cleanup. Alternatives have a large uncertainty (essentially factor of 2). EPA drawing of river banks on Figure 6 are arbitrary, inaccurate, and overstated and therefore, percentages within the error/uncertainty of analysis. DEQ will require all banks to be addressed under source control; many banks already addressed. Not in anyone's interest to address a remediation area or complete MNR evaluations if upland sources are not addressed.

### **EPA Response**

Regarding the contiguous nature of the river banks, the data and information regarding the extent of river bank contamination was provided by DEQ and reviewed by EPA should be representative of conditions described in the 2016 Portland Harbor Summary Report (DEQ 2016).

Regarding the decision node comment, data will be collected to evaluate river bank contamination. Design details such as the appropriate capping material will be identified during the design phase and will be reviewed by EPA and DEQ. DEQ may oversee river bank cleanup(s), subject to the ROD, that result in an earlier reduction of risk or otherwise advance overall sequencing of cleanup. PTW – NRC/NAPL are applicable to river banks because dissolved river bank contamination can be released to the river.

As described in the feasibility study report (USEPA 2016b) and the ROD, river bank soils may erode or be transported into the river and may become river sediments. Therefore, the PRGs for sediment, which are based on the RI and risk assessment, are appropriately applied to river banks. Post ROD data gathering will be used to develop designs for cleanup and will define the river bank areas that need to be addressed.

## **2.26.5 Explain Property-Specific Technology Assignments**

### **Comment Summary**

Comments were received from Northwest Pipe stating that proposed plan's SDU's inappropriately blend chemicals of concern, principal threat waste areas, and areas where no or limited contamination is found in such a manner that the scores of entities will not be able to sort out their relative potential responsibilities, making the allocation efforts impossible. The ROD needs to specify the quantities of technology assignments within each SDU (or SMA) determined to be appropriate for this complex site and the portion of the remedial action costs attributable to each.

## EPA Response

Allocation is not the intent or purpose of the feasibility study report (USEPA 2016b), proposed plan (USEPA 2016c), or the ROD and it will not be addressed in the ROD. Quantities are shown for each remedial alternative based on current information. The quantities for each alternative are based on SMAs as described in Section 3 of the feasibility study report. During remedial design, the information on sediment concentrations, groundwater plumes, reasonably anticipated land and river uses, plus other relevant information to an SMA will be updated for application of the decision tree and determination of where dredging, capping, and ENR is appropriate.

### 2.26.6 Consider Site Factors that May Impact Implementation

#### Comment Summary

Comments pertaining to how site factors can impact implementation of remedial technologies were received from four commenters, as summarized below:

- In applying their decision process to select technology assignments at various locations, it appears as though EPA did not consider location-specific factors that would limit the implementation of a selected remedy. The presence of over-steepened slopes, public utilities, piling fields, and other factors all impact the feasibility, cost, and duration of a selected remedy at a localized scale, and need to be considered in the technology assignments.
- EPA must take into account the continued operation of all public utilities in technology assignment and note that some technologies imply may not be implementable with certain existing utilities.
- EPA should identify how the presence of contaminated groundwater impacts technology assignments.
- EPA should acknowledge that areas for active remediation and technology assignments selected for feasibility study purposes will recognize existing upland source controls and will be refined during remedial design and implementation to allow site-specific and new information to optimize remedy effectiveness and reduce uncertainty.
- EPA should state in the ROD that technology assignments will be reevaluated during remedial design in a manner that includes comparative effectiveness using site-specific data and procedures consistent with the Gasco Consent Order (as was completed in the Gasco EE/CA), including current conditions associated with existing upland groundwater source controls.

#### EPA Response

In general, site-specific details will be considered and addressed during remedial design phase. EPA recognizes that there are existing and planned upland source controls as summarized in DEQ's Portland Harbor Upland Source Control Summary Report (last updated March 26, 2016). Please see DEQ's report and EPA's responses to source control comments in Section 2.27.1 of this responsiveness summary for further discussion of how Site-specific upland controls will be addressed during the remedial design phase.

The purpose of the more prescriptive technology assignment evaluation presented in the 2016 feasibility study report (USEPA 2016b) was not to ignore past evaluations but to provide a consistent and transparent Site-wide evaluation in order to estimate materials and costs to compare alternatives. The technology decision trees in the proposed plan (USEPA 2016c) were not meant to be prescriptive

but simply describe the general evaluation process used to select the remedy. The remedial design phase will entail a more detailed sampling effort to evaluate conditions. The ROD technology assignment decision tree provides a framework with flexibility and the ability to adjust remedial technologies based on more recent property specific information. This flexibility within the design is controlled by specific design requirements that accompany the ROD technology assignment decision tree.

For further discussion on how technology assignments may be impacted by public utilities and contaminated groundwater, please see EPA's responses in Sections 2.21.2 and 2.21.9 of this responsiveness summary.

### 2.26.7 Explain Technology Assignments for Shallow and Nearshore Areas

#### Comment Summary

Comments pertaining to technology assignments for shallow and nearshore area were submitted by two commenters, as summarized below:

- Shoreline dredging or capping would be infeasible at the Brix Property. Currently dredging is prescribed for the shallow areas. In addition to relatively shallow water, the structures and piles in the area make sediments in this area largely inaccessible. The removal area consists of native clays to silty clays that provide the base support for the upland slope. Removal of this compact native material at the base of this 2H:1V slope could destabilize the slope. Capping may also hinder access the fuel transfer station at a stationary work barge. The post-construction sediment concentrations are unrealistic and SWACs do not account for dredge residuals or actual background concentrations of COCs. For example, some of the dioxin/furan, PCB, and DDx post-construction concentrations are below EPA's derived background concentrations. Post-construction SWACs less than EPA's arbitrary background concentrations are not feasible and are an artifact of the use of "zeroes," instead of a background or equilibrium-based value, for replacement values in SWAC calculations.
- EPA should consider nearshore mudline/bank slopes and stability in assigning technology assignments. Geotechnical characteristics and submarine conditions limit application of some of the current proposed plan technology assignments. Assigned technologies according to the decision tree outline could result in significant shoreline and bank collapse and create upland structure instability.

#### EPA Response

The technology assignments in the feasibility study report (USEPA 2016b) are based on remedial investigation data. Footprints of dredging and capping at specific properties will be evaluated on a case-by-case basis during the remedial design phase. The presence of in-river structures, vessel draft requirements, and other location-specific conditions will be evaluated at that time to determine if the technology is feasible or appropriate.

The decision tree in the ROD provides for more detailed evaluations of geotechnical, hydrodynamic, and anthropogenic conditions during the remedial design phase. Appropriate technologies will be used in order to address any potential hazards in the area.

### 2.26.8 Consider Maintenance Dredging Effects on Technology Assignments

#### Comment Summary

Three commenters commented that areas subject to future maintenance dredging are much smaller than EPA assumed and that the FMD footprint should be revised, along with navigation depth requirements assumed within the FMD footprint.

Cascade General commented that the water depths in the small boat basin on the western side of Swan Island are currently more than adequate, and there will be no need to maintenance dredge this area for the foreseeable future. Likewise, the two dredge prisms in the dry-dock basin have been stable for at least 20 years, and there is no need for maintenance in this area for the foreseeable future.

#### EPA Response

The future maintenance dredge areas defined in the 2016 feasibility study report (USEPA 2016b) represented the locations of potential and known future dredge areas based on existing information. The FMD locations will be verified during the remedial design phase. Whether or not a potential FMD location will experience dredging in the future will need to be evaluated at the time of remedial design.

### 2.26.9 Better Define Habitat Mitigation Requirements

#### Comment Summary

The City of Portland commented that habitat mitigation requirements under the various alternatives are not described in a meaningful level of detail in the proposed plan or the feasibility study report. The City is concerned that the compensatory mitigation acreage could be underestimated, which could significantly impact cost estimates. Please clarify the calculation of compensatory mitigation acreage in the proposed plan.

#### EPA Response

Without pointing out a specific flaw in the calculations, EPA is unable to address this question. Table D2.n of Appendix D in the 2016 feasibility study report provides the acres assumed to require mitigation that were estimated for each alternative. Under the selected remedy, 60 acres of compensatory mitigation was assumed, based on armored capping acreages. This includes 2 acres of armored caps to be placed on river banks and 58 acres of armored caps to be placed on sediment in the shallow area, defined as above -15 feet CRD per the NMFS' definition of shallow water.

### 2.26.10 Provide Technology Assignment Flexibility

#### Comment Summary

A number of comments were submitted by six commenters that referred to how prescriptive the technology assignments were and requested more flexibility:

- Maintain flexibility in technology assignments so that areas appropriate for compensatory mitigation may be used accordingly.
- Flexibility should be built in for site-specific factors instead of by using generic assignments.
- Technology assignments should be flexible in the amount of dredging and in-place technologies.
- Technology assignments should take into account that the longer it takes to implement the remedy, the longer the impact to the river and fish, and the longer to recover.

- Flow charts need to be flexible to account for uncertainties in the CSM and the application of remedial technologies.
- There should be an evaluation in the suitability of alternative technologies in effectively reducing or isolating surface concentrations.
- ENR and activated carbon should be considered as active remedial technologies given the high sediment stability of the Swan Island SDU.
- ENR and activated carbon should be considered as active remedial technologies for RM 6NAV SDU
- Consider capping in the Nav-FMD areas where authorized and bathymetric conditions allow.
- EPA should correct the flawed assumptions regarding FMD requirements and propeller wash (propwash) disturbance depths in the Swan Island SDU, and should reevaluate potential remedial technologies within the Swan Island SDU based on these correction assumptions.
- EPA restricted capping site-wide due to a minority of situations. EPA has not presented any site-specific measurements of propeller-induced shear stress or sediment disturbance, instead relying on the presence of scour-pit at a few locations as evidence of substantial risk of propwash to capping.
- EPA does not have any basis to prescribe reactive caps with respect to groundwater plumes nor to specify the type of reactive cap (AquaGate + 10 percent PAC). EPA has failed to address the implementability of its prescribed reactive caps.

### **EPA Response**

To be clearer on the technology assignment criteria and process for implementing the ROD, a new decision tree with associated design requirements are included in the ROD and will provide a framework with more flexibility and other updates as a result of public comment. This decision tree flexibility (relative to ENR, capping, and dredging) is further discussed in Section 2.24 of this responsiveness summary.

### **2.26.11 Clarify the Decision Matrix**

#### **Comment Summary**

Comments were submitted by two commenters that referred multi-criteria decision matrix:

- The multi-criteria decision matrix should clarify that cap/cover technologies can be implemented in the Swan Island SDU feasibility study-defined propeller wash areas when site investigation demonstrates that the navigational depth is adequate to resist erosive forces.
- The multi-criteria decision matrix used for technology assessment and scoring provided in feasibility study Figure 3.4-16 is not understandable and not helpful in terms of assignment of technologies. In addition, the simplistic 1, 0, -1 scoring (yes-no approach) is not representative of the relative factors considered during selection of capping versus dredging for a given area. Specific changes to multi-criteria decision matrix were suggested in the first bullet below as part of the suggested changes to flow charts.

## EPA Response

The multi-criteria decision matrix was meant to describe the analysis that took place at the Site for cost estimates and volume calculations. Design requirements are specified in the ROD and PRPs may evaluate the site-specific factors to develop their design within the framework of the ROD technology assignment decision tree and design requirements.

### 2.26.12 Improve Technology Assignment Flow Charts

#### Comment Summary

There were a number of detailed comments about specific requested changes to the technology assignment flow charts. Recommendations for the flow charts were:

- The inclusion of multiple criteria that include pre-remedial design studies, geotechnical considerations, detailed sediment stability and propeller wash analyses, site-specific waterfront features, spatial differences in the river characteristics, and updated sediment and fish tissue concentration sampling data
- Having performance-based application of any reactive residual layer (e.g., flow chart requires placement of reactive residual layer regardless of post-dredge sediment conditions)
- Consideration of site-specific chemical and physical conditions in determining the need for reactive materials or armoring of caps
- Capping in navigation channel if authorized navigation depth could be accommodated
- Partial dredge and cap in NAV/FMD areas where bathymetric conditions would allow
- Use of alternative technologies, such as in-situ remediation or ENR where physical site constraints preclude placement of cap materials under structures
- Creating a single unified flow chart for Swan Island
- Specific notations on changes to wording in the flow charts

Related comments specific to Swan Island include:

- Use the intermediate decision trees when FMD area bottom depths are adequately below navigational depth
- Apply a mix of remedial technologies within the RAL footprint
- Apply ENR or MNR in the remainder of the Swan Island SDU outside other RAL footprint
- Conduct monitoring programs to assess performance and recontamination potential

## EPA Response

There were a number of detailed comments about specific changes to the technology assignment decision trees. EPA has noted the suggested changes to the decision trees and has revised the charts into one final decision tree included in the ROD. There was a misunderstanding about the decision trees intended for the propose plan as the prescriptive ones presented used were prepared for the 2016 feasibility study report (USEPA 2016b). EPA has developed a less prescriptive approach for the ROD that provides a framework, including design requirements that will be followed during the remedial design

process. This approach should address the specific comments about wording and flexibility in applying technology assignments at a site-specific level.

The Swan Island SDU recommendations are mostly incorporated already into the previously proposed technology assignments in the 2016 feasibility study report and proposed plan (USEPA 2016c). There will be a mix of remedial technologies based on location-specific features and ENR or MNR will be applied outside of the RAL footprint. The decision tree in the ROD provides a framework for design requirements and final technology design will be decided through the remedial design process and requested. Monitoring will occur at this time and after remedial technologies are placed to track short-term and long-term performance.

## 2.27 Source Control and Sediment Recontamination

### 2.27.1 Ensure Source Areas Are Controlled

#### Comment Summary

A total of 1389 comments were received on this topic. Almost all (98 percent) were received as form postcards or emails. The most common of those form comments are:

- “EPA’s cleanup plan should include the heavily contaminated uplands as well as the heavily contaminated river” or a slightly modified version.
- “Require the state of Oregon to continue upland sources control via legally enforceable means; the current text indicates that this approach “May” be taken.”

Several personal comments were received expressing concern about the status of upland source control and the split of responsibility between DEQ and EPA to address ongoing upland sources of contamination. One person believed that giving DEQ responsibility for upland and upriver sources meant that sources would not get addressed completely because DEQ has fewer resources than EPA. One person believed that DEQ’s method of identifying sources was insufficient and that DEQ (and so EPA) does not have a clear idea of where all the significant sources are. Representative personal comments include:

- “It seems reasonable that the upland contributors to river contamination should be cleaned up prior to actual river cleanup. Sadly, since DEQ is the lead agency on upland source cleanup, I don’t expect that to happen any time soon. The DEQ is chronically underfunded, understaffed, and not empowered to make industry complete cleanups in a timely matter.”
- “EPA should require the State of Oregon to continue its measures to control upland sources via legally enforceable means. Unfortunately, the approach suggested in the draft proposal indicates that such an approach may be taken and does not require it; we do not believe that language is sufficient.”
- “You can’t just clean up the river in the Portland downtown area and expect that to resolve the issue. The problem starts upstream from there in Newberg where they’re pulling out three-legged frogs and all kinds of crazy things. That’s an area that’s highly contaminated and that water flows downstream to Portland. Cleaning up the water that is coming into the river is what’s going to flush contaminants from the Willamette.”

- “It is true that there are hot spots of contamination that need to be addressed. It is also true that there are considerable volumes of fresh contamination currently entering the Portland harbor, not only from the local area, but upriver, beyond the Superfund site, from the hundreds of square miles drained by the Willamette and its tributaries.”
- “The upland sources, particularly the tank farms located in Linnton/Willbridge area, need to be controlled to prevent further contamination or recontamination of the river, with specific attention to earthquakes, flooding and climate change.”
- “Control of upland and upriver sources is necessary and not complete. The plan indicated a more pervasive influx of contaminant from the sources on land, many or all of which are uncontrolled. This problem must be remedied with source elimination in the harbor and source control upriver.”

Extensive comments were received on source control from numerous businesses, the USACE, and the Audubon Society. They are too large to quote directly and are summarized below:

- Several parties (ExxonMobil, Sediment Management Working Group, the USACE, PCI Group and the Audubon Society) believed that source control should be in place prior to remedy implementation.
- The Audubon Society asks that the previous cleanup work performed at early action/hotspot locations and the McCormick & Baxter site be re-examined for consistency with the RALs and PRGs for the Portland Harbor Site.
- The Associated Oregon Industries request source control and natural recovery processes already occurring in Portland Harbor be acknowledged as well as DEQ’s role in the Portland Harbor source control program since the Propose Plan and appears to be written to allow EPA to take over state-led work.
- The USACE included a specific request that groundwater source control be in place for the NW Natural plumes (Gasco) prior to remedy implementation in the relevant SDU that is adjacent to the NW Natural facility and U.S. Moorings facility.
- Siltronic Corporation requested that upland source control (especially as it relates to a remedy for NAPL) be in place prior to remedy implementation at the Gasco location.
- NW Natural requested that source control work completed at Gasco be acknowledged and utilized in the feasibility study and proposed plan in development of the preferred alternative. A similar comment from LWG asks that EPA not prescribe sediment remedies that ignore completed or committed upland source control measures.
- Comments from ExxonMobil, the Swan Island Group and the PCI Group ask that recontamination assessments be performed prior to remedy implementation.
- A comment from ARCO and BP West Coast Products notes that the natural movement of PAH-contaminated sediment from the Gasco location will recontaminate downstream areas.
- Comments from the Port of Portland and The Marine Group and BAE express concern that the 9 ug PCB PRG is unattainable in Swan Island Lagoon due to recontamination potential from urban background stormwater contributions.

## EPA Response

EPA is committed to ensuring that upland and upriver contaminant sources to the Willamette River are controlled because source control is critical in achieving the remedial action objectives for the Portland Harbor cleanup. In a February 2001 Memorandum of Understanding (MOU) (USEPA 2001), it was agreed that EPA would take the Lead Agency role and DEQ would take the Support Agency role for the in-river cleanup while DEQ would take the Lead Agency role using state authorities and EPA would take the Support Agency role for addressing upland and upriver contamination that may impact the Willamette River. EPA and DEQ jointly developed the December 2005 Portland Harbor Joint Source Control Strategy (DEQ 2005) to address the issue of uncontrolled upland and upriver sources of contamination to the river. The strategy provides the framework that DEQ follows in making upland and upriver source control decisions and provides the technical approach for characterizing upland and upriver sites and conducting source control evaluations for them.

Under the MOU, DEQ has coordinated their proposed source control decisions with EPA, six federal recognized Tribes, National Oceanic and Atmospheric Administration, Oregon Department Fish and Wildlife, and the U.S. Department of Interior. DEQ and EPA have coordinated even more closely on more complex upland sites, such as NW Natural and Arkema. Since the achievement of cleanup levels identified in the selected remedy relies in part on timely and successful completion of these upland and upstream source area actions, EPA retains the discretion to use its federal authorities to complete those actions. See Section 2.37 of this responsiveness summary for EPA's response on agency roles and cooperation. The Joint Source Control Strategy requires DEQ to prepare Milestone Reports. These reports provide an updated schedule and status of DEQ efforts to identify and control sources of contamination. Regular meetings are held between EPA and DEQ to discuss upland site source control decisions. EPA reviews and comments on most of DEQ's proposed source control decisions.

The status of the upland source control under the Joint Source Control Strategy framework was summarized in DEQ's Portland Harbor Upland Source Control Summary Report (DEQ 2016), dated November 21, 2014 and updated March 26, 2016. At the time of the updated report, DEQ had identified 495 commercial and industrial properties within the upland area, and of these sites, DEQ screened 171 sites for further evaluation. DEQ's goal is to control all upland sources prior to the initiation of in-river cleanup. The overarching goal of the Joint Source Control Strategy includes completing upland source control to the extent practicable prior to sediment cleanup in the Site. For example, a hydraulic control and containment system was installed at Gasco to capture and treat groundwater before it reached the Willamette River. EPA and DEQ are currently evaluating monitoring data and groundwater model flow predictions to determine if Gasco contaminated groundwater has been controlled sufficiently to begin in-river cleanup. A groundwater source control decision is expected from DEQ prior to remedy implementation near Gasco. Remedial design for the Gasco remedy will account for any NAPL (also known as Substantial Product) present in sediment. Source control work will be factored into remedial design (see also Sections 2.24 and 2.26 of this responsiveness summary).

Upland sources have been identified along the downtown reach of the river (approximately RM 12 through 16) that DEQ is working with to control and sediment contamination also exists within this reach. DEQ will be working with responsible parties at contaminated sites in the downtown reach of the Willamette River to ensure that the upland sources are controlled and the sediment contamination is addressed so that recontamination will not occur in areas subject to this ROD.

DEQ has placed regulatory controls on facilities to protect the water quality of the Willamette River from discharges of pollutants to the river. Most discharges of pollutants to the river require a NPDES permit under Oregon's authorized Clean Water Act Section 402 program. NPDES permits require dischargers to meet state water quality standards and total maximum daily loads (if applicable) in order to support all designated and potential beneficial uses. Periodic sampling is required under NPDES permits to ensure that discharges are in compliance with pollutant limits. Other regulatory controls related to bulk fueling facilities include the requirement to prepare and update spill prevention, control, and countermeasure plans to protect waters of the state from a release at facilities with petroleum storage.

In the selected remedy for the in-river cleanup, EPA has included remediation of a number of contaminated river banks immediately adjacent to sediment management areas that are documented uncontrolled sources of contamination to the Willamette River (see also Section 2.37 of this responsiveness summary).

Cleanup sequencing will be important for areas where a final sediment cap is installed as inputs from adjacent upriver cleanups will have the potential to recontaminate clean areas. As an example, cleanup of the area of the Willamette River offshore of Gasco should commence prior to areas in the downstream vicinity. A monitoring program will also be implemented to evaluate the long-term effectiveness of the remedy (Section 2.17 of this responsiveness summary). While source control efforts will be required permanently and serve to minimize the potential for recontamination, the monitoring program will be used to identify areas where recontamination may be occurring. Refer to the Section 2.3 of this responsiveness summary for a discussion of the feasibility of achieving the PCB cleanup level in an urban waterway such as Swan Island Lagoon.

Recontamination assessments are a component of pre-design or remedial design activities. The objective is to consider and evaluate upland, river bank, and in-river sources of potential recontamination and determine whether they were adequately investigated and controlled. See also the Sections 2.3 and 2.17 of this responsiveness summary regarding responses to concerns with unrealistic cleanup goals due to ongoing sources such as upstream inputs.

## 2.28 ICs

### 2.28.1 Develop a Plan for Implementing ICs

#### Comment Summary

Comments were received that stressed the need for EPA to develop a plan to implement ICs so that the public would be clear on the risks, the process involved, and the results.

Representative comments include:

- "We request that the 5-year plan describe how the results of monitoring could impact fish advisories both Site-wide and on a more localized scale, and how these results will be communicated to the public to inform the community about progress being made in the river cleanup."
- "EPA should explain how it intends to ensure that Institutional Controls are effective to prevent human exposure to contaminants. Include regular health screenings and provision of necessary medical treatment for vulnerable populations that may be affected by consumption of contaminated fish. Include strategies to conduct aggressive target outreach in the event of a spike

in toxicity levels in fish tissue, water column, sediments or air in which the public is likely to have exposure.”

A similar topic is addressed in environmental justice (Section 2.35.3 of this responsiveness summary).

### **EPA Response**

Effective ICs are key component of reducing risk at the Site and are critical to the successful implementation of the cleanup plan. EPA knows that many Tribal and community members fish for recreation, sustenance or because of long-held cultural traditions. EPA understands that issuing a fish advisory and posting warning signs may not be sufficient by themselves to adequately inform the public about risks at the Site.

During remedial design, the PRPs will develop an IC implementation and assurance plan (for review and approval by EPA) that lays out the approach for the development and implementation of all ICs required by the ROD to protect humans from exposure to site contaminants and to protect the remedy put into place. Specifically, the use of fish consumption advisories and regulated navigation areas, and the entities responsible for implementing them will be outlined. Additional IC mechanisms may be developed during remedial design, as needed.

The primary goal of the IC implementation and assurance plan is to establish and document the activities necessary to implement and ensure the long-term stewardship of ICs, and specify the persons and/or organizations that will be responsible for conducting these activities. In development of the plan, EPA will coordinate with river users, property owners, communities and other stakeholder groups to minimize the long-term impacts of ICs as part of the remedial action. The IC plan will include permitting aspects for ongoing maintenance throughout the area in this selected remedy as well as the downtown reach as well.

The approach for the fish consumption advisory IC will likely include, but not be limited to, the following:

- Survey fisher communities, including Tribal, low-income, minority, and immigrant communities, to verify the fish species being consumed, consumption rates, preparation and cooking practices.
- Develop a fish tissue sampling plan including species, numbers, and size of fish to be sampled, as well as tissue surrogates, such as passive sampling devices, where needed.
- Use fish tissue and other empirical data to support the five-year review process in evaluating the relative success of remedial measures against RAOs.
- Collect fish tissue data during remedial design (baseline) and throughout construction as part of the comprehensive monitoring plan for the Site.
- Establish fish consumption advisories that are fully protective of human health throughout construction and following construction based on on-going monitoring of fish tissue samples from upstream, within, and downstream of the Site.
- Conduct outreach and education tailored to the affected communities to ensure that fish consumption advisories are effective and appropriate, advisory signs are designed, installed, and maintained effectively and at the appropriate locations, in coordination with Oregon Health

Authority and Multnomah County Department of Health. Programs such as the education collaborative at Palos Verdes will be considered in development of the IC implementation and assurance plan.

- Identify and educate fisher communities about mechanisms to reduce the impacts of fish consumption advisories. The Agency for Toxic Substances and Disease Registry and/or Oregon Health Authority will review fish consumption information from EPA in their health assessment process, and offer health screenings if appropriate.
- Include coordination with sport or recreational fishing clubs and licensing locations
- Monitor the effectiveness of fish consumption advisories through surveys of fisher communities during construction.
- Based on long-term monitoring as determined in the five-year review process required under CERCLA, re-evaluate fish consumption advisories to ensure they are fully protective but not overly restrictive and on target to meet long-term goals of the remedial action. This may include special consideration of high use areas such as beaches and fishing areas at Cathedral Park, Willamette Cove, and Swan Island Lagoon.

## 2.28.2 Incorporate Education of the Public into Fish Consumption Advisories

### Comment Summary

About a dozen comments were received that were specific to educating people on risks from fishing so that they would be aware of and would heed the fishing advisories. It was pointed out that people currently fish at the Site even though fish advisories are in place (such as warning signs at the river). Commenters believe that a more robust public education effort would have to be used to ensure that impacted communities were aware of the health risks and the acceptable amounts of fish that could be eaten. One commenter has expertise specifically in Russian and the local Russian community and highlights the preference of this culture and community within Portland Harbor to fish and eat fish from the river.

Representative comments include:

- “The City requests that EPA address the feasibility of easing fish advisories for small home-range fish species in localized areas when the monitoring data indicate that fish caught from these exposure areas have recovered enough to do so.”
- “People still fish from the water and don't understand the adverse health effects. Warnings are posted in several locations, but they aren't everywhere. I would guess that a majority of the people I see are immigrants and need the fish they catch to feed their families.”
- “It is important that a better job is done with this clean up. Portland has a huge homeless population and many live on or near the river. These people are not reached through traditional outreach. These people and all Portlanders deserve to be able to use the resources that the Willamette offers. We need EPA to make sure that all people, not just healthy adults, can use the river and eat fish from the river.”
- “I'm an interpreter, translator, and I've worked with the East European Coalition ... and I'm here today because I know that the East European Coalition has a small grant aiming to engage and

inform the Russian speaking community, the East European community so to speak, multiple languages beyond Russian about this and I happen to know how common it is for Russians to go fish in the Willamette. I also have photographs that show multiple languages warning not to eat the fish out of the Willamette in four or five languages. So I'm eager to see that the broader community gets engaged in this project and is well informed both in terms of language, in terms of opportunity that they can participate, they can be informed to protect their own health but also how they can render development to their own community.”

- “To help the public better understand the fish advisories, please describe the reasons for the differences in advisories from the different agencies. The City also encourages EPA to partner with Oregon Health Authority in developing a means to communicate this process to the public. Please revise the communication strategy for EPA advisory so that it is more meaningful to the public. Due to the high reliance on fish advisories at the Site, the City would like EPA to perform a study to assess the effectiveness of fish advisories, to ensure they are successful in protecting the public.”

### **EPA Response**

Since the Site was listed in December 2000, EPA has conducted continuous outreach efforts and has engaged with organizations representing people who live along the river. Recent outreach activities are outlined in EPA’s most current iteration of the Portland Harbor Community Involvement Plan, which is available on EPA’s Portland Harbor Superfund website. EPA intends to continue these outreach efforts after the release of the final cleanup plan for the Site.

EPA recognizes that fish consumption advisories are challenging ICs to implement effectively without community support. EPA will work with the PRPs, tribes, community groups, appropriate state agencies (such as the Oregon Health Authority) and other parties to develop an education program for fish advisories and any other ICs that is specifically tailored to those most at risk (such as those who consume the greatest amount of fish such as tribal members and communities with environmental justice concerns). We will also draw on experience at other Superfund sites to improve on what works and avoid what does not. We will pay particular attention to understanding cultural nuances and overcoming communication issues and will rely heavily on advice from the Tribes and communities with environmental justice concerns in making this happen.

The outreach program may include informational meetings, presentations, and workshops targeting affected community groups; development and distribution of informational materials such as brochures or maps; advisory notifications communicated through a variety of culturally appropriate outlets; installation and maintenance of advisory signs at known fishing locations; and coordination with sport or recreational fishing clubs and licensing locations. This level of effort is specified in the ROD (Section 14), and it will be a priority in implementing the cleanup at the Site.

The five-year review will address the effectiveness of the ICs in evaluating protectiveness and EPA will also evaluate the feasibility of easing fish advisories as specific areas recover. EPA will also revise the communication strategy for the EPA advisory so that it is more meaningful to the public and will discuss the potential to perform a study to assess the effectiveness of fish advisories with the City of Portland.

EPA agrees that all areas that provide recreation, fishing or other public uses, including high-use areas such as beaches and fishing areas at Cathedral Park, Willamette Cove, and Swan Island Lagoon, should be given appropriate RAL assignments to limit exposure as quickly as possible through the

implementation of the appropriate remedial technology. During remedial design, EPA will further consider site-specific factors, including high public use, in prioritization of areas posing the highest risk, sequencing, and other aspects of how the remedial action will be implemented.

RAO 2 (protection of human health) will not be met until several years following construction, requiring fish consumption advisories at the Site and watershed-wide fish consumption advisories, such as the existing Oregon Health Authority advisory for mercury, would likely remain in place because there are sources of contamination that are outside of the scope of the Superfund cleanup. EPA acknowledges the need for improved risk communication regarding the acceptable fish meals (compared to the existing Oregon Health Authority fish advisory) and the timelines to meet RAO 2. However, given that this is a large and complex site, it is difficult to estimate the time to conduct the remedial design. The implementation of the selected remedy will dictate how the design will be conducted. It is unlikely that design and construction activities will be conducted in a single phase. Therefore, part of the post ROD activities will include remedy implementation planning. This work will be conducted and coordinated with stakeholders. EPA will continue to conduct community involvement activities that will keep the community and stakeholders engaged in the process and involved in the cleanup activities.

### 2.28.3 Reduce Use of ICs in General and Monitor Carefully

#### Comment Summary

Twenty-five comments were received relating to the effectiveness of ICs. People asked that the use of ICs be reduced where possible; and, where not possible, that measures be developed and implemented to ensure their effectiveness and make changes where needed. They requested that funding be set aside for evaluation and changes.

Roughly 85 percent of the comments were from email comments that stated:

- “Because Institutional Controls (ICs) are not effective, especially in the long term, EPA needs to reduce the need for ICs, and include in the ROD provisions for PRPs covering the costs of ICs, and provisions for evaluating the IC effectiveness with regular program modifications.”

The remaining comments were:

- “ICs do not work according to GAO. Therefore, cleanup goals should eventually eliminate use of ICs.”
- “ICs are not effective, especially in the long term. When ICs are utilized the potential responsible parties must cover the costs of these ICs for their duration, and provisions must be included for evaluating their effectiveness with regular program modifications.”
- “It is misleading to omit discussion of the ongoing need for fish advisories and the role, if any, that fact plays in EPA’s remedy selection.”
- “Please also reduce the need for ICs, and include in the “records of decision” provisions for “potentially responsible parties” covering the costs of any ICs that are implemented, as well as provisions for evaluating the IC effectiveness with regular program modifications.”
- “EPA states that existing fish consumption advisories might not be sufficiently effective in protecting human but does not propose an alternative fish advisory that should apply between now and the start of cleanup, which may be many years from now.”

## EPA Response

ICs are common components of CERCLA remedies to help prevent exposure to residual risks and protect remedies put into place. Over the years, EPA has improved its implementation of ICs to assure they are reliable in the long-term and EPA does not believe that ICs in general will be less effective at Portland Harbor than other cleanup sites. That said, EPA agrees that for ICs to be effective, EPA, the state and PRPs all will have a role in implementing, monitoring and enforcing ICs used at Portland Harbor.

Regulated navigation areas are a type of IC that ensures the integrity of sediment caps is maintained. Regulated navigation areas limit river activities in specific areas and could include prohibiting anchoring of vessels or the use of spuds to stabilize vessels in areas containing caps. Notifications such as signs and buoys may be used to warn vessels from the area. Other ICs may not include buoys, but may involve adding notation on navigation charts for areas that require coordination with EPA prior to dredging or other harbor maintenance work. Regulated navigation areas have been successfully used in the past to protect remedial actions at the Site and were required to protect the McCormick and Baxter cap and the Gasco interim action cap from vessel activities. Periodic inspections of regulated navigation areas notifications will be needed to ensure they are functional and effective. The IC implementation and assurance plan, to be developed during remedial design, will outline the approach for effective implementation and monitoring of regulated navigation areas (Section 2.28.1 of this responsiveness summary).

Other land use restrictions may be implemented through easements or other real property mechanisms. All ICs will be monitored and if found to not be working, additional or different controls can be applied or additional cleanup may be required.

EPA explained the need for fish consumption advisories in both the feasibility study report (USEPA 2016b) and the proposed plan (USEPA 2016c) based on the results of the BHHRA (Kennedy/Jenks 2013) in the remedial investigation report. EPA has clearly identified in the ROD the need for fish consumption advisories during and after construction of the remedy until cleanup levels are achieved. Even then, watershed-wide fish consumption advisories such as the existing Oregon Health Authority advisory may need to remain in place because there are sources of contamination that are outside of the scope of the Superfund cleanup (upstream sources of naturally-occurring mercury).

As described in Section 2.28.2 of this responsiveness summary, EPA acknowledges the challenges of fish consumption advisories and ensuring, the public is aware of the risks to eating resident fish and abides by the advisories to limit their consumption. That is one reason why EPA's remedy decision has sought to address as much risk through active cleanup as feasible and cost-effective. The objective of the remedy is to reduce contaminant concentrations in a variety of media mainly by actively targeting the sediment areas with the highest known concentrations of contamination and areas with contaminated groundwater impacting the river. This active remediation is expected to reduce fish tissue concentrations and associated human health risk and reduce the reliance on fish advisories. However, it should be noted that fish consumption advisories will remain no matter how well contaminated sediments and other media at the Site are remediated due to sources of contamination that are outside of the scope of the Superfund cleanup, as explained in Section 2.3.3 of this responsiveness summary.

Fish tissue monitoring is a part of the monitoring plan for the cleanup, as described further in Section 2.17.3 of this responsiveness summary, and parties responsible for the cleanup will also be responsible for funding the implementation of the monitoring plan. Monitoring data will be used in part to determine whether fish consumption advisories can be relaxed. During remedial design an IC

implementation and assurance plan will be developed by the PRPs for review and approval by EPA (Section 2.28.1 of this responsiveness summary), which likely will include a variety of ICs, some of which PRPs will implement and others will be governmental controls implemented local, state, and federal agencies with authorities to authorize uses of the river.

Regarding the commenter's statement that EPA claims that existing fish consumption advisories might not be sufficiently effective in protecting human health but has not proposed an alternative, fish consumption advisories are a state-led function and issuing an alternate advisory in a Record of Decision is not appropriate. However, EPA has taken and will continue to take action by conducting extensive outreach efforts, including coordinating with the Oregon Health Authority and Oregon DEQ to inform particularly vulnerable communities of risks associated with contamination in the river. One example of these outreach efforts specific to fish consumption advisories began in 2012 when EPA the Willamette Riverkeeper, the Oregon Health Authority, and the Department of Portland Parks & Recreation worked with different groups such as the Portland Harbor Community Advisory Group, five neighborhood associations and representatives from the Slavic, Latino and Vietnamese communities and the Yakama Nation to review the previous fish advisory sign in order to design a more useful sign. Multiple focus group sessions occurred with these community and tribal partners in addition to extensive meetings between Oregon Health Authority and EPA. The result of this extensive outreach was a revised fish advisory sign that incorporated community and tribal input.

## 2.29 Remedy Compatibility with Current and Future Use

### 2.29.1 Prevent Conflict with USACE Dredging

#### Comment Summary

The USACE believes the scope of the Site cleanup interferes with its critical missions and should address only SMAs defined in the proposed plan. For USACE projects outside of SMAs, an existing guidance - the SEF and implementation process - through the Portland Sediment Evaluation Team should continue to be used to evaluate contamination levels and manage sediments removed for maintenance dredging purposes within the Federal Navigation Channel as well as by other project proponents (such as the Port of Portland).

USACE believes that the existing SEF will continue to allow unconfined aquatic placement of dredged material (such as disposal upstream of the Site or in the Columbia River flow lane) while the application of the PRGs will preclude it. They commented that the geographic scope of the application of PRGs needs to be clearly defined and is concerned if the PRGs are applied up to Willamette Falls (RM 26.8) and commented that if PRGs are applied to RM 28.4 that could result in the removal of a valuable resource from the Lower Willamette and Columbia River Systems. They believe that the preference of the NMFS would be that dredged material from the Site meeting the SEF could be disposed unconfined upstream of the Site and in the Columbia River.

#### EPA Response

USACE appears to be most concerned about the PRGs associated with the human health fish tissue and sediment goals and did not provide specific information about the SEF nor any quantitative support demonstrating why under that framework sediment evaluation, particularly for bioaccumulative toxics, would result in significantly different results from the CERCLA evaluation of risk and disposal options. The SEF (in Sections 8 and 9) provides for assessing bioaccumulative contaminants and where appropriate undertaking site-specific risk assessments which in the case of the State of Oregon would be using DEQ's cleanup program's risk assessment guidance. Thus, it is not clear why decisions under the

SEF as applied would be significantly different, especially once bioaccumulation values have been developed for use in the SEF.

PRGs for Portland Harbor were developed in compliance with the NCP and EPA guidance to reduce unacceptable risk to people and ecological receptors determined through site-specific CERCLA risk assessments. The PRGs represent concentrations in environmental media which are protective of both human and ecological receptors for each RAO for the cleanup. The PRGs were developed on the basis of site-specific and default risk-related factors, chemical-specific ARARs, and consideration of upstream sediment background concentrations. The sediment background concentrations were derived from data taken as part of the remedial investigation and were developed in accordance with CERCLA guidance. In making CERCLA remedial action decisions, EPA must apply the CERCLA statutory and regulatory standards.

Under CERCLA's standards, the entire in-river portion of the Site presents unacceptable risk to people and wildlife consuming resident fish from bioaccumulation of PCBs chlorinated dioxins, DDT and metabolites in fish tissue, which includes areas outside of SMAs. Beyond site-wide fish consumption risks, risks to the benthic community as measured through comparison to site-specific and national sediment quality guidelines are present throughout the in-river portion of the Site. The final remedy selected monitored natural recovery for areas in the Navigation Channel and other areas that may need future maintenance dredging outside of the SMAs. Monitoring will occur in those areas and, if MNR is not occurring, more active remediation may be needed.

EPA and the USACE have a Letter of Agreement on coordinating USACE dredge projects with the EPA cleanup program. We anticipate continuing to work with the USACE under that Letter of Agreement post-ROD. However, with the final ROD issued, EPA anticipates that future maintenance including dredging within the area covered by the selected remedy and downtown reach, will be evaluated consistent with the final ROD and cleanup levels for purposes of evaluating both what contaminant concentrations may be exposed by the dredging and making decisions regarding where the dredged sediment can be disposed. Sediment containing COCs exceeding PRGs in areas outside of SMA's needs to be managed consistent with EPA's ROD to minimize discharges of contamination during dredging and exposure of contamination as a result of the dredging and disposal that poses unacceptable risk. EPA will continue to perform a supporting role to the USACE in review of permit applications for projects in Portland Harbor under Section 404 of the Clean Water Act to ensure adequate project controls are in place during in-river sediment disturbing activities.

With regard to dredged sediment from the Site and the potential for unconfined disposal in the Columbia River, based on current information and EPA's risk assessments, EPA could not sanction the placement of CERCLA dredged material in the Columbia River that exceed human health PRGs or any of the ecological PRGs for bioaccumulation or other relevant exposure scenarios that would apply to unconfined in-river disposal.

Regarding the geographic scope of EPA's cleanup levels, EPA's ROD provides where remedial action in the river has been selected. The final ROD requires cleanup from RM approximately 1.9 up to RM 12, based on current information but post-ROD baseline sampling may change the exact upstream or downstream area for cleanup. The cleanup levels will be applied to where remedial action will be taken. The ROD also provides that the downtown reach from approximately RM 12 to 16.6 is a source area that needs to be addressed through DEQ source control actions consistent with EPA's ROD so as not to recontaminate lower areas of the river. EPA's sediment cleanup levels for arsenic, hexachlorobenzene,

PCBs, cPAHs, 1,2,3,4,7,8-HxCDF, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, and 2,3,7,8-TCDD are based on sediment background concentrations derived consistent with EPA guidance based on sampling undertaken as part of the remedial investigation studies above RM 15.3 and thus are considered to be achievable. Other information in the administrative record supports that all other risk-based sediment cleanup levels are achievable as well.

EPA's ROD relies significantly on MNR in a majority of the Site to achieve the cleanup goals from cleaner sediment coming into the Site from upstream. Therefore, the USACE and the State of Oregon should consider potential impacts on the Portland Harbor Site in performing or authorizing dredge projects above RM 16.6 and particularly for considering unconfined aquatic disposal of dredged material exceeding EPA's cleanup levels. EPA's ROD also considers the benefits of the cleanup on further migration of contamination to the Columbia River. Furthermore, EPA is looking to the state to take a watershed approach in seeking to reduce toxics in the upper Willamette River so as to facilitate achievement of the ROD goals and benefit human health and the environment in the entire watershed. EPA is willing to coordinate with the USACE and state on upriver dredging projects.

Regarding the USACE comment that it would be NMFS' preference to allow Portland Harbor dredged sediment to either stay in the river or be disposed of in the Columbia. We note the USACE provided no supporting documentation of NMFS' views on the Portland Harbor cleanup and disposal issues. However, EPA is coordinating with NMFS and USFWS for compliance of the remedy with Endangered Species Act. EPA received comments from NMFS during the public comment period. EPA's understanding of NMFS's position is they feel that long-term improvements in sediment quality would represent a reduced risk to salmon. Further, EPA in its consultation process has met with the Yakama and other area tribes who have voiced concerns over contaminant loading to the Columbia River. The fact that the SEF does not address bioaccumulation of PCBs and other bioaccumulative toxins in fish tissue is a paramount concern of Tribes that have historically and currently fish in the Columbia and Willamette Rivers.

## 2.29.2 Prevent Conflict with City's Comprehensive Land Use Planning

### Comment Summary

The City of Portland had the following comment regarding land use:

- "EPA must ensure that the Site-wide remedy and the remedial design for specific areas be consistent with the anticipated future land uses of Portland Harbor established by the City.

Every Superfund remedy must be selected with consideration of future land use (CERCLA Land Use Directive, OSWER No. 9355.7-04, 1995 reaffirmed in the directive to Superfund National Policy Managers, OSWER 9355.7-06P in 2001). Oregon has unique land use laws that require development of enforceable land use plans and Portlanders are passionate about their involvement in planning the City's future land use.

Portland recently adopted an updated comprehensive land use plan to guide development and investment in the City for the next 20 years, as well as a Climate Action Plan, and the City has enacted detailed zoning overlays that apply to Portland Harbor. These requirements and development standards define, protect and enhance the anticipated future uses in Portland Harbor, including industrial lands that support middle-wage incomes, habitat protection, critical flood control, and public access to recreation.

Much of Portland Harbor is designated as prime industrial land and thus the selected remedy and any associated technology assignments should not create physical or economic barriers to redevelopment on this economically valuable land. It is especially important that prime industrial land that is currently vacant be allowed to build docks or dredging moorages as needed to access the federal navigation channel. Portland's land use planning also provides specific community visions for how public access, riverine habitat and flood storage potential will be maintained and improved. Portlanders have worked hard to incorporate the right mix of uses in Portland Harbor. This includes extensive plans for greenways and human access trails in some areas of the Harbor.

Portland's land use planning process has created a clear vision of the anticipated land uses in Portland Harbor. In short, Portlanders anticipate that all land in Portland Harbor will be used to fill multiple community needs. The City requests that EPA engage City land use planners and the communities in and around Portland Harbor to ensure that anticipated future land uses in each area of the river are not impaired by the remedy, and that EPA provide flexibility in the ROD's application of cleanup technologies to be consistent with the detailed planning in place for current and anticipated land use."

### EPA Response

EPA and the City of Portland, as a member of LWG, worked together on the remedial investigation and feasibility study and consideration of harbor use was incorporated into the development of PRGs (see 2.29.1). The primary goal of Superfund cleanup is to be protective of human health and the environment, and reasonably anticipated future uses plays an important role in cleanup decisions. EPA intends to be flexible in the implementation of the remedy, and those details will be developed in the remedial design and beyond. See also EPA's responses to comments in Sections 2.2.6, 2.21, 2.26, 2.35, and 2.37 of this responsiveness summary.

## 2.30 Miscellaneous Regulatory and Legal Issues

### 2.30.1 Be Consistent in Treatment of PRPs

#### Comment Summary

Two comments were received on the inconsistent treatment of PRPs.

- One commenter stated that the proposed plan does not provide the amount of information about sources of contamination as required by EPA guidance because the proposed plan does not fully describe the United States' involvement in WWII ship building and related activities that contributed to the contaminants found in the Portland Harbor. The commenter said that the ROD needs to clearly describe how these activities have significantly impacted the Site and that an important function of the proposed plan, comments on the proposed plan, and ROD is to serve as the basis for an allocation of liability among PRPs. It was stated that EPA has not identified all significant PRPs and identified the L.B. Foster Company, a former steel-pipe manufacturing facility at the WWII Assembly Building area. The commenter requested that EPA's issue a GNL and 104(e) Request to the L.B. Foster Company.
- A second commenter stated that parties with no or *de minimis* or *de micromis* contaminant contributions be removed from the PRP settlement process, and that to their knowledge EPA Region 10 has not yet implemented early settlement, *de minimis*, or *de micromis* settlement procedures.

## EPA Response

As noted in the EPA guidance titled, *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA (Interim Final, October 1988)* (USEPA 1988), “[t]he remedial investigation and feasibility study process as outlined in this guidance represents the methodology that the Superfund program has established for characterizing the nature and extent of risks posed by uncontrolled hazardous waste sites and for evaluating potential remedial options.” The results of the remedial investigation and feasibility study support the proposed plan (USEPA 2016c) and eventual the selected remedy. The remedial investigation, feasibility study, proposed plan, and the remedy decision document are not the vehicle for identifying potential responsible parties or allowing contributions. That is a separate function. EPA disagrees with the commenter’s view more specific and extensive PRP information should have been in the proposed plan and should be in the ROD. Likewise, allocation of liability between PRPs is not a function of these two documents, but rather their primary function is to present the alternatives that were evaluated, communicate a proposed remedy for public participation and comment, and then to document the selection of the final remedy needed to protect human health and the environment.

The remedial investigation report (USEPA 2016a), Sections 3 and 4, contain significant information regarding the historical and current land uses in the Site and the sources from those uses that released contamination into the river. The major industries that operated along the river are summarized in Section 3.2 and includes discussion of World War I and II shipbuilding and dismantling of US Navy and U.S. Maritime Administration ships. EPA guidance does not discuss the level of detail about specific PRPs that the commenter asserts should be in the proposed plan and ROD. In fact, Section 6.3.2. of the ROD guidance provides that “specific PRP names need not be included” in the ROD. The list of PRPs identified as of the date of the proposed plan is in the administrative record [AR Doc #850002] which includes all federal agencies, departments or entities that have to date been identified as potentially liable for response costs.

The comments and information supplied by commenters regarding a company that may have operated on its property in the past and potential settlements with *de minimis* or *de micromis* parties are not related to the proposed remedy for the Site; therefore, will not be addressed in this responsiveness summary,

### 2.30.2 Explain Why Standard Procedures Appear to Be Misapplied

#### Comment Summary

Comments were received from NW Pipe Company, the Port of Portland, and Portland General Electric specific to misapplication of standard procedures. Those comments are:

- EPA has required that public access for fishing be provided at river bank areas that are on private property. The PRP should not have to provide the public access to their private slip. Or Site access or security limits risk.
- The International Terminals Slip was created through dredging upland areas and it does not share the same characteristics as the Willamette River. EPA has applied the same standards to the International Terminals Slip, an artificial creation, as it does the Willamette River, a natural feature.
- Alternative I was included in the feasibility study report after the draft version and has not been reviewed by NRRB and the Contaminated Sediments Technical Assistance Group.

**EPA Response**

Through its cleanup decision, EPA is not requiring landowners to provide fishing access or other public access to private property. The public has access to some portions of the Willamette River's banks and boats can access most portions of the river. Ecological receptors such as fish have access to all areas of the river, and may be exposed to COCs located in and near the International Terminals Slip. These fish then travel to other parts of the Willamette River where they can be caught and eaten by people and wildlife or birds. Therefore, sediments in the International Terminals Slip present can pose an unacceptable risk, regardless of whether or not people have access to the slip or not. See also Section 2.2.9 of this responsiveness summary.

Northwest Pipe Company has not provided a technical description of standards that are applied to the Willamette River that should not be applied to the International Terminals Slip. The characterization of the Willamette River in the remedial investigation report accounts for anthropogenic and natural activities. Under the proposed plan (USEPA 2016c), remedial action objectives are applied across the Site regardless of how particular areas were originally created.

**2.30.3 Explain Why LWG's Feasibility Study Was Not Sufficient****Comment Summary**

Union Pacific Railroad stated that EPA has delayed the process by revising LWG's 2012 draft feasibility study report (LWG 2012) which fulfilled the requirements of the law and EPA guidance. Union Pacific Railroad commented that the LWG feasibility study report proposed a workable, common sense cleanup that incorporated reliable science, and provided the required comparative analysis of alternatives based on realistic estimates of cost and time necessary to perform work.

**EPA Response**

See EPA's position to LWG Dispute Issue 2 (Appendix A of this document).

**2.30.4 Consider that Flaws in the Proposed Plan Will Encourage Litigation****Comment Summary**

Two commenters (Calbag Metals Co. and EVRAZ) commented on litigation concerns. They state that because the proposed plan is flawed (such as RAOs and associated PRGs are overreaching; components are technically and factually unsupported), a ROD based on the current proposed plan will likely result in litigation. This will result in long delays and increased costs to the PRPs due to litigation. EPA will then need to use its enforcement powers to compel performance of unilateral cleanup orders.

**EPA Response**

The purpose of the responsiveness summary is to respond to public comments on the remedial alternatives evaluated and supporting information and proposed plan (USEPA 2016c), not to address questions of liability or litigation in any detail. EPA anticipates that the parties responsible under CERCLA will pay for the cleanup and trusts that those parties will see the benefits of moving forward with the cleanup rather than litigation.

**2.30.5 Respond Fully to Freedom of Information Act Requests****Comment Summary**

One commenter (PCI Group) states that because EPA has not responded fully to their Freedom of Information Act request, EPA has not made the proposed plan's "supporting analysis information

available in the administrative record.” Therefore, EPA has not provided the public a reasonable opportunity to comment on the proposed plan, which is required under the NCP.

### **EPA Response**

The proposed plan (USEPA 2016c) and administrative record file contains the information that the agency considered. Any interested stakeholder has all the information needed to comment on the alternatives, including the preferred alternative, developed for remediating from approximately RM 12 to RM 2. Whether or not EPA had responded to Freedom of Information Act requests (which generally are not included in the administrative record) is not relevant to the completeness of the administrative record file. Neither the NCP, nor EPA’s guidance, suggest any intersection between EPA’s compiling of the administrative record file, and its response to Freedom of Information Act requests.

The administrative record file was delivered to the Multnomah County Central Library, the St. Johns Library and the Kenton Library with an additional copy also placed at the Historic Kenton Firehouse. Additionally, EPA’s Portland Harbor Superfund webpage provides a web link to the full administrative record (<https://semspub.epa.gov/src/collection/10/AR64506>). Consistent with EPA’s 2010 “*Revised Guidance on Compiling Administrative Records for CERCLA Response Actions*,” EPA has continued updating the administrative record file during the preparation of the responsiveness summary.

## **2.31 Support for Another Alternative**

### **2.31.1 Consider Community Support for Alternatives B, E, G, G+, or H**
