**Portland Harbor Superfund Site**

**Portland, Oregon**

**U.S. Environmental Protection Agency Region 10**

**Seattle, Washington**

**January 2017**

## **PART 1: DECLARATION FOR THE RECORD OF DECISION**

### **SITE NAME AND LOCATION**

Portland Harbor Superfund Site

Portland, Multnomah County, Oregon

Superfund Site Identification Number: ORSFN1002155

### **STATEMENT OF BASIS AND PURPOSE**

This Record of Decision (ROD) presents the Selected Remedy for the in-river portion of the Portland Harbor Superfund Site (the Site) in Multnomah County, Oregon. The Selected Remedy was chosen in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), and to the extent practicable, the National Contingency Plan (NCP). This decision is based on the Administrative Record file (Appendix V) for the Site. The State of Oregon concurs with the Selected Remedy.

### **ASSESSMENT OF THE SITE**

The response action selected in this ROD is necessary to protect public health or welfare or the environment from actual or threatened releases of hazardous substances into the environment and pollutants or contaminants which may present an imminent and substantial endangerment to the public health or welfare.

### **DESCRIPTION OF THE SELECTED REMEDY**

The Selected Remedy is a final action for the in-river portion of the Site from approximately river mile (RM) 1.9 to 11.8. It addresses unacceptable human health risks associated with consumption of resident fish and shellfish and exposure to in-river sediments, surface water, and groundwater. It also addresses ecological risks to wildlife that consume fish, shellfish, and other biota, as well as bottom-dwelling organisms (benthic invertebrates), fish, and wildlife from exposure to sediment, surface water, and groundwater.

The overall strategy for addressing contamination at the Site has included actions at various locations throughout the Site, including upland source control work conducted by the Oregon Department of Environmental Quality (DEQ) and other enforcement and cleanup actions within the Site at the following locations: Terminal 4 (RM 4.5 East), NW Natural (RM 6 West), Arkema (near RM 7 West), U.S. Moorings (near RM 6 West), Triangle Park (RM 5 East), Gasco (RM 6.5 West), River Mile 11E Project Area, McCormick and Baxter Superfund NPL Site (RM 7 East), Gould Superfund NPL Site (RM 5 West), and BP Arco Bulk Terminal (RM 4.5 West). Additional details regarding these cleanup actions are provided in ROD Section 2.3.

The Selected Remedy addresses all areas where contaminant concentrations exceed the cleanup levels through a combination of technologies, including capping, dredging/excavation, in-situ and ex-situ treatment, enhanced natural recovery (ENR), monitored natural recovery (MNR), and institutional controls (ICs). Certain contaminated river banks will be addressed using the same remedial technologies that will be used for the adjacent contaminated sediment, if it is

determined that those river banks should be remediated in conjunction with the sediment action. Caps can be constructed of layers of clean material and can be augmented with reactive amendments in areas with groundwater plumes and/or constructed as armoured caps in higher energy environments. ENR includes placement of clean material over low-level contaminated sediments, with reactive amendment such as activated carbon, as required, to reduce contaminant concentrations. MNR relies on natural processes such as burial of contaminated sediments by cleaner sediments from upstream. All areas with principal threat waste (PTW) will be addressed by active remediation, not MNR. Dredged material will be sent to off-site disposal facilities, either Resource Conservation and Recovery Act (RCRA) Subtitle D or C compliant, as appropriate.

In the Proposed Plan, EPA requested public comment on all of the proposed alternatives. As discussed in the Decision Summary, EPA received comments on all alternatives, including numerous comments that the Preferred Alternative in the Proposed Plan was not protective enough of human health and the environment. In response to this new information, EPA selected a different alternative that will more closely address the concerns raised through public comments.

The Selected Remedy will include a total constructed area of 394 acres of sediment and 23,305 lineal feet of river bank and will allow 1,774 acres of sediment to recover naturally. The construction will include 365.3 acres of capping and dredging contaminated sediment and 28.2 acres of ENR. Additionally, the 23,305 lineal feet of river bank are assumed to be either excavated or covered with an augmented reactive cap or an engineered cap using beach mix or vegetation. The Selected Remedy also requires compensatory mitigation for loss of habitat resulting from the cleanup, currently estimated at 60 acres.

The Selected Remedy includes dredging of approximately 215.2 acres of sediment to varying depths (3,017,000 cubic yards [cy]) and excavating approximately 123,000 cy of contaminated material from river banks. The need for, and extent of, ex-situ treatment will be based on the off-site disposal requirements and material testing during design and construction. For purposes of the FS, disposal locations and requirements were assumed and cost estimates were calculated based on those assumptions. If, during design, more proximate or cost-effective disposal facilities emerge, EPA would support use of these options to reduce the cost and environmental impact of the cleanup.

As part of the FS, observed current uses were assumed to continue in the river. As part of the public comment period, some parties identified that the potential future use(s) of a part of the river may be other than current uses or EPA's assumptions. To ensure that the correct reasonably anticipated future uses are used for the remedial design, these assumptions will be verified and will be altered, as appropriate. For example, eliminating the need for a more expensive dredge and armored cap remedy may be possible if a significant area is no longer to be used for marine terminal purposes.

The Selected Remedy is estimated to take 13 years to construct. As the cleanup is constructed, levels of contamination in fish tissue are expected to decline over time until levels of contamination in resident fish reach background anthropogenic levels.

The Selected Remedy includes short-term monitoring during construction and long-term monitoring of caps, dredge areas, and MNR areas after construction to evaluate long-term effectiveness and ensure the remedies function as designed.

ICs will be implemented to: (1) protect human health and the environment by limiting exposure to contamination left in place and (2) protect the long-term integrity of the engineered components of the Selected Remedy. An Institutional Control Implementation and Assurance Plan (ICIAP) will be developed during remedial design which will, at a minimum, set out the specifics of the ICs and measures that will be implemented and who will be responsible for implementing, enforcing, and monitoring each IC. Among others, three types of ICs that will be used are described further below:

- **Fish Advisories and Educational Outreach:** A fish advisory is currently in effect for the Lower Willamette River. Once construction is complete, the advisory will be updated to allow an increased consumption rate based on fish tissue concentrations. The advisory may be periodically updated until Remedial Action Objectives and cleanup levels are reached. The outreach program to communicate with the public regarding risks from consumption of contaminated fish may include: informational meetings, presentations, and workshops targeting affected community groups; development and distribution of informational materials such as brochures or maps; advisory notifications communicated through a variety of culturally appropriate outlets; installation and maintenance of advisory signs at known fishing locations; and coordination with sport or recreational fishing clubs and licensing locations.

**Waterway Use Restrictions or Regulated Navigation Areas (RNAs):** Where caps will be utilized to contain contamination in navigable areas of the river, waterway use restrictions may be implemented to ensure the integrity of the cap is maintained in perpetuity. These restrictions may preclude boat anchoring and keel dragging, the use of spuds to stabilize vessels, structure and utility maintenance and repair, and future maintenance dredging in areas containing caps. Notifications such as signs and buoys placed by the Oregon Marine Board may be used to warn vessels away from the area. Periodic inspections of RNA notifications will be needed to ensure they are functional and effective and will be evaluated in five-year reviews.

- **Land Use/Access Restrictions:** Land use or access restrictions will be implemented in nearshore areas and river banks to maintain the integrity of caps from current or future activities, such as construction and maintenance of structures. Where needed, coordination with Oregon's Department of State Lands (DSL) and adjacent landowners will be conducted to implement land use or access restrictions. Monitoring, including inspections, will be conducted to ensure that restrictions are functioning as intended.

Since the Selected Remedy will leave contamination in place above levels that allow unlimited use and unrestricted exposure, five-year reviews will be conducted as required by CERCLA. Other types of controls that likely will be used include coordinated permit reviews of in-river work (e.g., maintenance dredging, pile removal) that will be necessary to minimize recontamination to the Site.

Total estimated net present value costs (discounted at 7 percent) for the Selected Remedy are \$1,054,200,000. The total non-discounted capital costs are \$1,184,607,000 and periodic costs are \$524,028,000.

## **STATUTORY DETERMINATIONS**

The Selected Remedy is protective of human health and the environment, complies with federal and state requirements that are applicable or relevant and appropriate to the remedial actions (unless justified by a waiver), is cost effective, and uses permanent solutions and treatment technologies to the maximum extent practicable.

Although CERCLA § 121(b)(1), 42 U.S.C. § 9621(b)(1), expresses a preference for selection of remedial actions that use permanent solutions and treatment technologies to the maximum extent practicable, there are situations that may limit the use of treatment, including when treatment technologies are not technically feasible or when the extraordinary size or complexity of a site makes implementation of treatment technologies impracticable. The Selected Remedy will generate approximately 2,481,000 to 3,308,000 cy of contaminated sediments through dredging. The Selected Remedy will address all principal threat waste (PTW) by excavation and off-site disposal or, if left in place, with augmented reactive caps to provide in-situ treatment. Additionally, as necessary, dredged or excavated PTW will be treated prior to disposal if required by state or federal regulations. The Selected Remedy is estimated to provide ex-situ treatment of approximately 191,500 cy of contaminated sediment and river bank soil. In-situ treatment such as cap amendments will be applied over 133 acres. With these treatment actions, the preference for treatment requirement of the NCP has been met.

The Selected Remedy will result in hazardous substances, pollutants, or contaminants remaining on-site above levels that allow unlimited use and unrestricted exposure. Therefore, statutory reviews will be conducted every five years after the initiation of the remedial action to ensure the remedy continues to provide adequate protection of human health and the environment.

## **DATA CERTIFICATION CHECKLIST**

The following information is included in the Decision Summary section of this ROD. Additional information can be found in the Administrative Record file for this Site.

- Contaminants of Concern (COCs) and their respective concentrations are in Section 6, "Summary of Site Characteristics."
- Baseline risks for human health and the environment represented by the COCs are in Section 8, "Summary of Site Risks."

- Cleanup levels established for COCs and the basis for these levels are in Section 9, "Remedial Action Objectives."
- How source materials or highly toxic materials that are PTW are addressed is in Sections 6, "Summary of Site Characteristics", and 14, "Selected Remedy".
- Current and reasonably anticipated future use assumptions used in the baseline risk assessment and ROD are in Section 7, "Current and Potential Future Site and Resource Uses."
- Estimated capital, operation and maintenance (O&M) and total present value costs, discount rate, and the number of years over which the remedy cost estimates are projected in Section 14.3. "Summary of Estimated Remedy Costs."
- Key factors that led to selecting the remedy (i.e., how the Selected Remedy provides the best balance of tradeoffs with respect to the balancing and modifying criteria, highlighting criteria key to the decisions) are in Section 11, "Comparative Analysis of Alternatives." and Section 14, "Statutory Determinations."

%	percent

## **PART 2: THE DECISION SUMMARY**

### **1. SITE NAME, LOCATION, AND BRIEF DESCRIPTION**

The Portland Harbor Superfund Site, as listed on the National Priorities List (NPL) (Superfund Site ID#: ORSFN1002155), includes an in-river and an upland portion. The Site was listed on the NPL in December 2000 mainly due to concerns about contamination in the sediments and the potential risks to human health and the environment from consuming the fish. This Record of Decision (ROD) describes the remedial alternatives that were considered and selects a final remedy for the in-river portion of the NPL site from approximately river mile 1.9 to 11.8, and does not include actions to address the upland portion. The terms Site, harbor-wide, and Site-wide used in this document in relation to the Selected Remedy generally refer only to the in-river portion of the NPL site being addressed in this ROD.

This ROD was developed by the Environmental Protection Agency (EPA), the lead agency for the in-river portion of the Site, in consultation with the Oregon Department of Environmental Quality (DEQ), the support agency. After listing the Site on the NPL in 2000, EPA entered into a 2001 Memorandum of Understanding (MOU) with the DEQ, six federally recognized Native American Tribes (tribes), two other federal agencies, and one other state agency.<sup>1</sup> Under the MOU, DEQ is the lead agency for addressing contamination in the upland portions of the Superfund Site, and EPA is the support agency. The MOU partners have all provided input in the development of the remedial investigation/feasibility study (RI/FS), which in large measure was conducted by a group of potentially responsible parties (PRPs) under an Administrative Settlement and Order on Consent (AOC). EPA conducted an extensive search for PRPs and, to date, has identified about 150 parties as potentially responsible for releases of hazardous substances to the river, so this is an enforcement/PRP-financed site.

The Selected Remedy addresses approximately a 10-mile reach of the lower Willamette River in Portland, Multnomah County, Oregon (Figure 1 in Appendix I), which is an urban and industrial section of the river north of, and downstream of, downtown Portland, Oregon. The Site covered by this ROD is approximately 2,190 acres and extends from river mile (RM) 1.9 (upriver end of the Port of Portland's Terminal 5) to RM 11.8 (near the Broadway Bridge).

While the harbor area is heavily industrialized, it is located within a region characterized by commercial, residential, recreational, and agricultural uses. Land use along the lower Willamette River in the harbor includes marine terminals, manufacturing, and other commercial operations, as well as public facilities, parks, and open spaces. In addition to industrial activities, the Willamette River and surrounding watershed historically offered access to abundant natural

---

<sup>1</sup> Government parties that signed the MOU include: Oregon Department of Environmental Quality, the Confederated Tribes and Bands of the Yakama Nation, the Confederated Tribes of the Grand Ronde Community of Oregon, the Confederated Tribes of Siletz Indians, the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes of the Warm Springs Reservation of Oregon, the Nez Perce Tribe, the National Oceanic and Atmospheric Administration, the U.S. Department of the Interior (National Marine Fisheries Service and U.S. Fish and Wildlife Service), and the Oregon Department of Fish and Wildlife.

resources in the river and on land. Many of these resources are still present such as fish, marine mammals, waterfowl, land mammals, and native plants.

The Willamette River is also important to many tribes. Fish are among the resources most frequently utilized by the tribes in the Portland Basin and the Willamette Valley. Culturally significant species include salmonids, lamprey (eels), eulachon (smelt), and sturgeon. Native people also fished for a variety of other resident species, including mountain whitefish, chiselmouth, northern pikeminnow, peamouth, and suckers (Butler 2004; Saleeby 1983). The harvest of the Pacific lamprey was, and continues to be, important to many tribes. Native plants were and continue to be gathered for food and medicinal purposes as well. Tribes have reserved hunting, fishing (particularly salmon and sturgeon species) and certain gathering rights through Treaties with the United States. These activities provide food for Tribal families and cultural heritage knowledge and skills. Tribal uses of these resources continue today, but access to suitable patches of habitat continues to be both a challenge and an essential element of maintaining local Tribal cultural knowledge, practices and traditions.

Contamination in the Site reflects the historical industrial, marine, commercial, defense, and municipal practices for over 100 years in this active industrial, urban, and trade corridor. Contaminants continue to reach the river through erosion of contaminated soils and river banks, and through groundwater and stormwater discharges. Upstream sources within the broader Willamette River Basin contribute to contamination in sediment, surface water, and biota at the Site. The human health and ecological risk assessments concluded that contamination within the Site poses unacceptable risk to human health and the environment due to the presence of a variety of contaminants. There are 64 contaminants of concern (COCs) at the Site, with most of the human health and ecological dietary risks attributed to polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), polychlorinated dibenzo-*p*-dioxins and furans (dioxins and furans), and pesticides such as dichlorodiphenyltrichloroethane (DDT).

## **2. SITE HISTORY AND ENFORCEMENT ACTIVITIES**

This section provides background information on past activities that have led to the current contamination at the Site and federal and state investigations and cleanup actions conducted to date under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and other authorities.

### **2.1. Site History**

The Willamette River is the 19th largest river in the United States and is one of 14 American Heritage Rivers in the country. The Willamette River flows into the larger Columbia River, which eventually flows into the Pacific Ocean. Even though the Willamette is nearly 100 river miles from the Pacific, there are tidal influences within the Site and overall, it is a very large and dynamic river. During its 309-mile course, which ends at its confluence with the Columbia River, it drains 11.7 percent (%) of the area in the State of Oregon. In 1891, the Oregon State Legislature created the Port of Portland. Since the late 1800s, the Portland Harbor section of the lower Willamette River has been extensively modified to accommodate a vigorous shipping industry. Modifications include redirection and channelization of the main river, draining

seasonal and permanent wetlands in the lower floodplain, and relatively frequent dredging to maintain the navigation channel, access to docks, and wharf facilities. Constructed structures, such as wharfs, piers, floating docks, and pilings, are especially common in Portland Harbor where urbanization and industrialization are most prevalent. These structures largely accommodate or support shipping traffic within the river and stabilize the river banks for urban development. Riprap is the most common bank-stabilization method although upland bulkheads and rubble piles are also used. Seawalls help control periodic flooding as most of the original wetlands bordering the river in the Portland Harbor area have been filled.

Historically, contaminants from many facilities entered the river system from different activities including, but not limited to: ship building and repair; ship dismantling; wood treatment and lumber milling; storage of bulk fuels; manufactured gas production (MGP); chemical manufacturing and storage; metal recycling, production and fabrication; steel mills, smelters, and foundries; and electrical production and distribution. These activities have resulted in direct discharges from upland areas through storm water and waste water outfalls, releases and spills from commercial operations occurring over the water, municipal combined sewer overflows (CSOs), and indirect discharges through overland flow, bank erosion, groundwater, and other nonpoint sources. In addition, contaminants from off-site sources have reached the Site through surface water and sediment transport from upstream and through atmospheric deposition. Operations that continue today along the river banks include bulk fuel storage, barge building, ship repair, automobile scrapping, recycling, steel manufacturing, cement manufacturing, operation and repair of electrical transformers (including electrical substations), and many smaller industrial operations.

A federal navigation channel, with an authorized depth of -40 feet (ft) Columbia River datum<sup>2</sup> (CRD), extends from the confluence of the lower Willamette River with the Columbia River to RM 11.6. Container and other commercial vessels regularly transit the river. Certain parts of the river require periodic maintenance dredging to keep the navigation channel at its authorized depth. In addition, the Port of Portland and other private entities periodically perform maintenance dredging to support access to dock and wharf facilities. Dredging activity has greatly altered the physical and ecological environment of the river in Portland Harbor. The current navigation depth was authorized in 1962 and dredging work on the authorized 40-ft-deep channel from Portland and Vancouver to the Pacific was completed in 1976. In 1999, Congress authorized the Willamette River to be deepened to 43 ft; however, this has not yet occurred. Swan Island Lagoon was created in the 1930s when dredge spoils were used to fill in part of the channel and connect Swan Island to the mainland. The Willamette River channel, from the Broadway Bridge (RM 11.6) to the mouth (RM 0), varies in width from 600 to 1,900 ft. The U.S. Army Corps of Engineers (USACE) maintains the navigation channel.

---

<sup>2</sup> CRD is used as the nautical chart datum for the lower Willamette River. CRD is a reference plane established by the USACE in 1912 by observing low water elevations at various points along the Columbia and Willamette rivers (USACE 1966). Consequently, CRD is not a fixed/level datum but slopes upward as one moves upstream. River users can obtain the depth on a chart and apply tide or river-level gauge readings, relative to CRD, to compute actual water depth. Low water values are used for navigation charting to provide conservative depth values in the event accurate tide data are not available to the river user.

Development of the river has resulted in major modifications to the ecological function of the lower Willamette River. However, a number of species of invertebrates, fish, birds, amphibians, and mammals, including some protected by the Endangered Species Act (ESA), use habitats that occur within and along the river. The river is also an important pathway for migration of anadromous fish such as salmon and lamprey. Various recreational fisheries, including salmon, bass, sturgeon, crayfish, and others, use the lower Willamette River. Resident fish in the Site include but are not limited to: smallmouth bass, brown bullhead, black crappie, and carp.

## **2.2. Previous Investigations**

Numerous investigations have been conducted of the Portland Harbor Site dating back to the 1920s; however, most studies were conducted from the late 1970s through the 1990s. Some investigations were conducted on a larger scale (e.g., several river miles) while others were conducted on a smaller scale (e.g., less than 1 river mile). Larger scale investigations typically were conducted by or for federal or state agencies, such as USACE, the U.S. Geological Survey (USGS), the Oregon Department of State Lands (DSL), the Oregon Department of Fish and Wildlife (ODFW), the DEQ Water Program, and EPA, to assess the river system. Smaller scale investigations typically were conducted by private parties for the purposes of maintenance dredging, construction and maintenance of in-river structures, or assessment of fate and transport of contamination from upland or in-river releases.

As part of EPA's RI/FS process, nearly 700 documents and data sets were obtained that address conditions in the lower Willamette River. This information was used to develop an initial understanding of the physical, chemical, and biological processes at the Site and to assist in the development of the conceptual site model (CSM).

EPA conducted a Preliminary Assessment and Site Investigation (PA/SI) in May 1998 (Roy F. Weston 1998). Sediment data collected during the PA/SI and previous investigations resulted in the NPL listing of the Site.

## **2.3. Enforcement Activities and Cleanup Actions Planned or Completed to Date by EPA**

On September 28, 2001, 10 PRPs that call themselves the Lower Willamette Group (LWG) entered into an AOC with EPA to conduct the RI/FS. Two AOC Amendments were also signed by these parties and EPA in 2003 and 2006.

The cleanup or control of the upland contamination that provides ongoing contaminant sources to the river is, and will be, conducted primarily under DEQ oversight using state authorities. DEQ and EPA updated the Portland Harbor Joint Source Control Strategy – Milestone Report (DEQ 2010), which describes how to identify, evaluate, and prioritize upland sources of contamination that are affecting or may affect the Willamette River in the Portland Harbor area. DEQ's source control activities are summarized in the Portland Harbor Upland Source Control Summary Report, updated in April 2016 (DEQ 2016). It is posted on DEQ's website: [www.deq.state.or.us/portlandharbor/](http://www.deq.state.or.us/portlandharbor/).

In addition to the RI/FS work conducted under an AOC with the LWG and the source control work conducted by DEQ, other enforcement and cleanup actions have occurred or were initiated at several areas within the Portland Harbor Superfund Site, and are summarized below.

- **Terminal 4 (RM 4.5 East):** The Port of Portland and EPA signed an AOC for a Removal Action in October 2003. The Port of Portland completed a Phase I Abatement Measure in 2008. Phase I consisted of dredging and off-site disposal of 12,819 cubic yards (cy) of contaminated sediment, capping contaminated sediment with an organoclay-sand mix cap in the back of Slip 3, and capping and stabilizing the bank along Wheeler Bay. The Port also conducted a 60% design of a confined disposal facility (CDF) in Slip 1.
- **NW Natural (RM 6 West):** NW Natural and EPA signed an AOC for a Removal Action in April 2004. The Removal Action was conducted at the Gasco Manufactured Gas Plant facility between August and October 2005. Approximately 15,300 cy of tar-like material and tar-like contaminated sediment were dredged from the river bank and nearshore area adjacent to the Gasco facility and disposed of off-site in a permitted disposal facility. An organoclay mat and sand cap was also installed over the dredged area.
- **Arkema (near RM 7 West):** Arkema Inc. and EPA signed an AOC for a Removal Action in June 2005. Arkema conducted some site characterization and preliminary design evaluations. However, the AOC was terminated in March 2016, and no cleanup actions have been taken to date.
- **U.S. Moorings (near RM 6 West):** EPA issued a Resource Conservation and Recovery Act (RCRA) 3013 order to the USACE for an upland source investigation in June 2007. USACE completed an RI/FS for upland sources and addressed an area where potentially erodible, contaminated soils were found.
- **Triangle Park (RM 5 East):** The University of Portland and EPA signed a Bona Fide Prospective Purchaser Agreement and an Order on Consent for an Upland Removal Action in December 2006 and an Amendment in April 2009. The four main components to the completed removal action included institutional controls (ICs), groundwater monitoring, excavation, and capping.
- **Gasco (RM 6.5 West):** NW Natural, Siltronic Corporation, and EPA signed an AOC for a Removal Action in September 2009. NW Natural and Siltronic are conducting site characterization and design evaluations for the area offshore of their two facilities. They have also agreed to perform further characterization, studies, analysis, and preliminary design for the final remedy at the Gasco Sediment site. The studies and other work under the agreement were incorporated into the Portland Harbor RI/FS. No cleanup actions have been conducted to date.
- **River Mile 11E Project Area:** Cargill, Inc., CBS Corporation, City of Portland, DIL Trust, Glacier Northwest, Inc., PacifiCorp, and EPA signed an AOC for a Supplemental RI/FS in April 2013. Site characterization work was conducted from 2013 to 2015, although no cleanup actions have been conducted to date.

- **McCormick and Baxter Superfund NPL Site (RM 7 East):** The selected remedy for this wood treatment facility addressed both in-river and upland portions of the site and was completed in September 2005. As part of this cleanup, a cap was placed on 23 acres of nearshore and submerged land adjacent to the facility. DEQ is the lead for operations and maintenance (O&M) at the site, and five-year reviews are conducted since waste is left in place. The most recent five-year review was conducted in 2016. Results indicated that the remedies for soil, sediment, and groundwater are functioning as intended and are protective of human health and the environment.
- **Gould Superfund NPL Site (RM 5 West):** A remedy addressing upland soils at this secondary lead smelter and battery disposal site was completed in September 2000 and the site was deleted from the NPL in 2002. Five-year reviews are conducted since waste is left in place. The next five-year review will be conducted in 2017.

EPA has also conducted an extensive search for PRPs and, to date, has identified about 150 parties as potentially responsible for releases of hazardous substances to the river. EPA has identified PRPs through general notice letters beginning in December 2000, and the most recent notices were sent in January 2014. All PRPs were notified of their opportunity to comment on the Proposed Plan.

### 3. TRIBAL COORDINATION AND CONSULTATION

Throughout the RI/FS process EPA engaged in government-to-government consultation and coordination with the MOU partner tribes and has encouraged and facilitated tribal involvement consistent with the Policy on Consultation and Coordination with Indian Tribes (May 2011). EPA also applied its Guidance for Discussing Tribal Treaty Rights (February 2016) in recognition that the Site impacts treaty-reserved or other fishing rights.<sup>3</sup> EPA's consultation and coordination included several methods of interaction with tribes, including coordination, pursuant to the MOU, through the Technical Coordinating Team (TCT), and conducting formal tribal consultations. Government-to-government consultations occurred in January and February of 2016 in anticipation of the Proposed Plan. Another round of consultations occurred in July 2016 during the public comment period. Finally, EPA included tribal communities living in the Portland area in its outreach efforts.

EPA considered numerous factors, such as tribal fish consumption rates and the effects of contamination at the Site on treaty-protected resources, to develop remedial alternatives for the Site. EPA recognizes that the MOU partner tribes have treaty-reserved or other fishing rights in areas impacted by the Site. Once implemented, the cleanup will improve fish habitat and help further the tribes' rights to fish.

---

<sup>3</sup> EPA Policy on Consultation and Coordination with Indian Tribes, May 4, 2011. Incorporates the Executive Order 13175 "Consultation and Coordination with Indian Tribal Governments," November 2000 and Presidential Memorandum, November 5, 2009. See also EPA Policy on Consultation and Coordination with Indian Tribes: Guidance for Discussing Tribal Treaty Rights, February 22, 2016.

#### 4. COMMUNITY PARTICIPATION

This section summarizes the community involvement activities, including public meetings conducted by EPA during the RI/FS and the remedy selection process. EPA developed the initial community involvement plan in 2002 and has continually updated the plan to promote meaningful public engagement during all phases of the Superfund process for the Site. This plan was developed based on interviews with community members and stakeholders. Throughout the RI/FS, EPA has conducted many community involvement activities, such as:

- Holding public information sessions and participating in community advisory group meetings
- Holding quarterly stakeholder meetings to provide updates on Site activities
- Seeking input from community groups and natural resource agencies on sampling plans, the human health and ecological risk assessments, and other RI/FS documents
- Preparing and providing fact sheets to inform the community about Site progress
- Providing information about EPA's work at the Site at annual community festivals
- Providing regular updates at neighborhood meetings

EPA's outreach goal is to educate the community about the work being done at the Site and collaborate with stakeholders on how to successfully engage the public. In 2002 EPA developed a Community Involvement Plan (CIP) after interviewing community members and other stakeholders. The CIP has been updated throughout the RI/FS process. Since the Site was listed, EPA has used public information sessions, fact sheets, websites, one-on-one discussions, and participation in community events as ways to share information about the Site with the broader community. Furthermore, EPA has provided financial support to the Willamette Riverkeeper since 2001 via a technical assistance grant (TAG) which allows a community group to contract their own technical advisor to interpret and explain technical reports, site conditions and EPA's proposed cleanup proposals and decisions. The Willamette Riverkeeper has used this TAG to give support to the Portland Harbor Community Advisory Group (CAG) which provides a public forum for community members to learn about the Site and share community needs and concerns. Additionally, EPA established a listserv for the Site that now has over 3,000 subscribers as a method for sharing information and relevant events quickly and efficiently.

EPA made significant community outreach efforts leading up to the release of the Proposed Plan to get community input and to prepare people to participate in the public comment period. These efforts included producing and disseminating quality information such as community information cards, fact sheets, and videos; establishing information repositories at the Multnomah County Central Library, the St. Johns Library, and the Kenton Library where the public can review documents associated with the Site; maintaining current information on EPA's Portland Harbor website; providing valuable information via the EPA Portland Harbor listserv; sustaining strong partnerships with DEQ, the Oregon Health Authority (OHA), and the City of Portland to maximize community outreach efforts; attending and presenting at public forums and meetings; and organizing multiple community information sessions during January, February, and March of 2016. A detailed list of specific community involvement activities is available in EPA's current Portland Harbor Community Involvement Plan (accessible on EPA's website at

the following link:

[https://www3.epa.gov/region10/pdf/ph/sitewide/community\\_involvement\\_plan\\_june2016.pdf](https://www3.epa.gov/region10/pdf/ph/sitewide/community_involvement_plan_june2016.pdf)).

Additionally, EPA has engaged with many different groups over the years, including groups that represent or are concerned about communities with environmental justice concerns. EPA takes environmental justice seriously and has worked to understand environmental justice concerns in the Portland Harbor Site by using existing tools (such as EPA's Environmental Justice Screen tool and Community-Focused Exposure and Risk Screening Tool), applying the six principles of environmental justice that are outlined in Executive Order 12898 (Environmental Justice: Guidance Under the National Environmental Policy Act) and working with community groups. Some of the main groups that EPA has engaged with at the Site include Communities of Color, Native American Youth Association, Latino Network, Right 2 Dream Too, Right 2 Survive, Willamette Riverkeeper, the Slavic Immigrant Association, Ecumenical Ministries of Oregon, the Coalition of Black Men, the Oregon Environmental Justice Task Force, Oregon Tradeswomen, League of Women Voters, Verde, Portland Harbor Community Coalition, Sierra Club Portland, Occupy St. Johns, Audubon Society, Asian Pacific American Network of Oregon, Vietnamese Community of Oregon, Portland neighborhood associations, and schools. EPA will continue to work with these groups and other interested parties to make sure that future outreach efforts reach historically underrepresented communities.

The RI report (EPA 2016a), FS report (EPA 2016b), and Proposed Plan (EPA 2016c) for remediation of the Site were released to the public for comment on June 8, 2016 via the web site <http://go.usa.gov/3Wf2B>. These documents were also made available to the public in the Administrative Record file maintained at the following five locations: Multnomah County Central Library, St. Johns Library, Kenton Library, EPA Region 10 Oregon Operations Office, and EPA Region 10 Superfund Records Center. A notice of availability of the Administrative Record was published in the Oregonian (both print and online) on June 8, 2016. EPA also developed a community fact sheet summarizing the Proposed Plan and an acronym, glossary, and contaminant summary in English, Spanish, Vietnamese, Chinese, and Russian) to support public outreach.

A 60-day public comment period for the Proposed Plan and supporting documents was originally set for June 8, 2016 to August 8, 2016. EPA received multiple requests for an extension to the comment period; therefore, EPA extended it through September 6, 2016, providing 90 days for public comment. EPA accepted comments at public meetings, by mail, and also established a web mail box to accept emailed public comments.

During the public comment period for the Proposed Plan, EPA held four public meetings in June and July of 2016 (June 24, June 29, July 11, and July 20). These public meetings were well advertised via e-mail, posting on the Portland Harbor website, dissemination of media advisories, and directly posting EPA notices in The Oregonian, The Skanner, The Asian Reporter, El Hispanic News (translated into Spanish), KAHOH (translated into Russian) and the Phuong Đông Times (translated into Vietnamese). The meeting venues were widely spaced throughout the metro area (City of Portland Building, EXPO Center, University Place Conference Center, and the Ambridge Center). Two formal presentations of the Proposed Plan were given at each

meeting, followed by a question and answer period and an informal open house where the public could discuss the plan directly with EPA staff and ask questions one-on-one. At all public meetings, there were opportunities to provide both written and oral comments on the proposed plan for the record. Language interpreters were available in person at the June 24<sup>th</sup> meeting (Spanish, Russian, Vietnamese and Chinese) and at the July 20<sup>th</sup> meeting in the evening (Spanish, Russian and Arabic) and by telephone, if needed, at the June 29<sup>th</sup> and July 11<sup>th</sup> meetings. A community fact sheet as well as an acronym, glossary, contaminant summary, and a handout detailing how to give written or oral comments were available in English, Spanish, Vietnamese, Chinese and Russian at each public meeting.

A summary of comments received during the public comment period and EPA's responses are included in the Responsiveness Summary, Part 3 of the ROD.

## **5. SCOPE AND ROLE OF THE RESPONSE ACTION**

EPA's remedial strategy for the in-river portion of the Site is to address all contaminated media and complete exposure pathways that pose unacceptable risk to human health or the environment (see Summary of Site Risks in Section 8 of the ROD), including sediment, biota, surface water, groundwater, and river banks.

EPA's Selected Remedy utilizes a combination of technologies, including capping, dredging/excavation, in-situ and ex-situ treatment, enhanced natural recovery (ENR), monitored natural recovery (MNR), and institutional controls (ICs). Certain contaminated river banks will be addressed using the same remedial technologies that will be used for the adjacent contaminated sediment, if it is determined that those river banks should be remediated in conjunction with the sediment action. Although the Selected Remedy does not directly address surface water, EPA anticipates that taking action on sediment and river banks, in conjunction with control of upland sources conducted under DEQ authority, will reduce contaminant concentrations in all media, including fish tissue, groundwater, and surface water, to acceptable levels. In addition, remediation of the sediment in the Site will also reduce the ongoing source of contaminants to Multnomah Channel and the Columbia River. The in-river action in this ROD is a final remedial action. Remedial action objectives (RAOs) will be met through reduction of contaminant concentrations in all media, thereby significantly reducing human health and ecological risks at the Site to acceptable levels.

The cleanup or control of the upland contamination that provides ongoing contaminant sources to the river is, and will be, conducted primarily under DEQ oversight using state authorities. When these state actions are complete, they are expected to meet or be more stringent than CERCLA's remedial requirements. It is expected that controlling these upland sources will reduce or eliminate contamination in soil, groundwater, and surface water migrating to the in-river portion of the Site. EPA is relying on the Oregon DEQ to use its authorities to address these sources. It is expected that controlling these sources will reduce or eliminate contamination in soil, groundwater, storm water, and surface water that migrates to the Willamette River. Since the achievement of cleanup levels identified in the Selected Remedy relies in part upon timely and successful completion of these upland and upstream source area actions, EPA retains the

discretion to use its federal authorities to complete those actions. DEQ's source control activities are summarized in the Portland Harbor Upland Source Control Summary Report, updated in April 2016 (DEQ 2016).

The McCormick and Baxter Site (RM 7 East) is a separate Superfund site located within the Portland Harbor Site. A final CERCLA remedial action was completed at the McCormick and Baxter Site in 2005 and, therefore, is not included in this remedial action. Additionally, two areas of the Portland Harbor Site have had some early removal actions completed to address contaminated river banks and/or sediment under EPA authority. These actions have occurred at Gasco (2005) and Terminal 4 (2008) (see Section 2.3). Final actions for these areas will be addressed through the action selected in this ROD.

Implementation of the Selected Remedy is discussed in Section 14.2.11.

## **6. SUMMARY OF SITE CHARACTERISTICS**

The RI report (EPA 2016a), prepared by the LWG and modified by EPA, describes the nature and extent of contamination at the Site; RI results are summarized below. Baseline human health and ecological risk assessments were completed and are summarized in ROD Section 8. In 2012, the LWG prepared a draft FS for the Site pursuant to the AOC. EPA modified the LWG's 2012 FS and finalized the document in June 2016 (EPA 2016b). The FS is summarized in Section 10 of the ROD.

This section summarizes information obtained during the RI and other investigations conducted before or during the RI/FS. More detailed information is included in the RI report (EPA 2016a).

### **6.1. Conceptual Site Model**

The CSM is a tool used to communicate site conditions and support the decision making process for managing contaminated sites. The CSM briefly identifies key Site characteristics such as sources of contamination, contaminated media and exposure pathways for human and ecological receptors.

The human health CSM is presented on Figure 2 in Appendix I. Current and historical industrial activities and processes within the Site have led to chemical releases from either point or nonpoint sources, including discharges to the river from direct releases or via outfalls and groundwater within the Site as shown on Figures 3 and 4 in Appendix I. In addition, releases that occur upstream of the Site and atmospheric deposition from global, regional, and local emissions may also represent potential contaminant sources to the Site. Chemicals in sediment and water may be accumulated by organisms living in the water column or by benthic organisms in sediments. Fish and shellfish within the Site feeding on these organisms can accumulate chemicals in their tissues through dietary and direct exposure to sediment and water. Humans can be exposed to contamination through direct contact (ingestion or dermal absorption) with sediments or surface water or through consumption of fish and shellfish.

The CSM for ecological receptors is presented on Figure 5 in Appendix I. This figure illustrates how contaminants released from the primary sources of Site contamination are transported

throughout the environment to media such as sediment, surface water, tissue, and transition zone water (TZW or pore water). Risks to ecological receptors exposed to Site contaminants are assessed by evaluation of assessment endpoints and environmental media.

## **6.2. Site Overview and Physical Characteristics**

The Site covered by this ROD is approximately 2,190 acres and includes the downstream portion of the lower Willamette River (RM 1.9 to RM 11.8). Multnomah Channel is a distributary channel of the lower Willamette River that begins at RM 3.1 and flows northwest approximately 21 miles to its confluence with the Columbia River. Upstream flooding is largely controlled by numerous major tributary reservoirs and dams along both the Columbia River and the Willamette River. In the lower Willamette River, especially in the vicinity of Portland Harbor, the channel banks have been stabilized in several areas by the placement of riprap and construction of seawalls and bulkheads. These measures have created a much more stable channel in the lower Willamette River. Some river bank areas and adjacent parcels have been abandoned and allowed to revegetate, and beaches have formed along some modified shorelines. These extensive physical alterations have resulted in a river reach that bears little resemblance to its pre-industrialized character in terms of flow dynamics, capacity, sediment movement, ecological habitat, and human uses.

The Willamette River originates within Oregon in the Cascade Mountain Range and flows approximately 187 miles north to its confluence with the Columbia River. The lower reach of the Willamette River from RM 0 to approximately RM 26.5 is a wide, shallow, slow moving segment that is tidally influenced, with tidal reversals occurring during low flow periods as far upstream as RM 15. The lower reach has been extensively dredged to maintain a 40-ft deep navigation channel from RM 0 to 11.6.

Historically, the lower Willamette River that flows through the Site was shallow and meandered, but it has been redirected and channelized via filling and dredging. The federally maintained navigation channel from RM 0 to 11.6 extends nearly bank-to-bank in some areas (currently varies in width from 600 to 1,900 ft), doubles the natural depth of the river, and allows transit of large ships into the active harbor. Today, this section of the river is deeper and narrower, with higher banks that reduce flooding during high-flow events.

Tidal influences also impact the flow of the river, with tidal reversals occurring during low flow periods as far upstream as RM 15. Tidal fluctuations can result in short-term flow reversals (i.e., upstream flow) during low river stage combined with a large variation in tide levels, which can occur in late summer to early fall when ESA listed species are least likely to be present, and, therefore, when active remediation is generally conducted. Near the river, tidal action can greatly alter groundwater flow directions, rates, and water quality and can increase the rate of river bank erosion.

The upstream dams have dampened river flows during seasonal and storm events. The Columbia River also plays a role in the flow dynamics of the Willamette River. In spring, high flows in the Columbia River can increase the hydraulic head at the confluence, causing the Willamette River to be detained and reduce flows until water levels drop in both river systems.

### **6.2.1. Geographical and Topographical Information**

Land elevations in Portland Harbor vary from 0 to 300 ft, with buttes as high as 650 ft. Portland Harbor is located in a geological depression known as the Portland Basin, bordered to the west by the Tualatin Mountains (also known as the West Hills or Southwest Hills of Portland), which are a spur of the Northern Oregon Coast Range, and to the east by a 120-foot-high natural bluff that runs along the northeast border of the Site.

Most of the lowlands on either side of the Willamette River within Portland Harbor are located on a terrace with elevations that range between 30 and 50 ft above sea level, mostly composed of fill material. The lowlands extend for approximately 0.5 to 1 mile from the river before reaching the Tualatin Mountains to the west or the natural bluff that runs along the northeast border of the Site. These lowlands primarily constitute the upland portion of the Site.

### **6.2.2. Site Geology**

The Portland Basin is a bowl-like structure that is 40 miles long and 20 miles wide and bounded by folded and faulted uplands. The Tualatin Mountains define the western edge of the Portland Basin; groundwater and creeks and channels along the east face of the mountains flow into the Willamette River.

The basin has been filled with up to 1,400 ft of alluvial and glacio-fluvial flood deposits since the middle Miocene (approximately 12 million years ago). These sediments overlie older (Eocene and Miocene) rocks including the Columbia River Basalt Group (CRBG), Waverly Heights basalt, and older marine sediments. The older rocks are exposed where uplifting has occurred (e.g., RM 7, west side in the Doane Lake area) on the margins of the basin, including adjacent to the Site.

Because the Site is located at the edge of the basin, both the older rocks and overlying sediments are present near the surface and play a significant role in defining interactions between groundwater and the river. The geologic units in the vicinity of the Site are illustrated in RI Figure 3.1-1.

### **6.2.3. Site Hydrogeological Features**

The general groundwater flow systems of interest recognized along the Site, from uppermost to lowermost, include: Fill, Fine-grained Facies of Flood Deposits, and Recent Alluvium (FFA); Coarse-grained Flood Deposits and Upper Troutdale Formation (CGF); Lower Troutdale Formation/Sandy River Mudstone; and CRBG. A deeper, regional flow system also is present, but it is not considered to be important in understanding the interactions between upland groundwater and the river.

The FFA hydrogeologic unit is of primary importance in defining the interactions between upland groundwater and the river because: (1) the unit forms most of the river channel within the Site as well as the surrounding upland areas and, therefore, controls groundwater interactions with the river; and (2) most groundwater contaminant plumes in the upland areas occur within

this unit. The hydrogeologic units are presented in RI Figure 3.1-2. RI Figure 3.1-3 presents the generalized conceptual picture of groundwater flow through these flow systems.

The Willamette River is the focus of discharge for the three flow systems. The shallow flow system is the primary focus of most upland groundwater investigations by DEQ because most of the upland groundwater affected by contaminants is present within this system. It discharges to the shallow and nearshore areas where exposure to human and ecological receptors is most likely. The impact to sediments from the shallow and intermediate flow systems is the focus of the RI, except at locations where the CGF and CRBG appear to be impacted by contaminants and are connected to the river.

#### **6.2.4. Bathymetry and Sediment Characteristics**

Most of the Site covered by this ROD is from –30 to –50 ft CRD (RI Map 3.1-9) and is dominated by the authorized federal navigation channel, which runs from RM 0 (Columbia River) to RM 11.7 (Broadway Bridge) and extends nearly bank-to-bank from RM 4 to 6 and from RM 8 to 11.7. Elevations in the navigation channel are generally –40 to –50 ft CRD. Except along the western channel edge from RM 8 to 10 where extensive shoaling has occurred, these portions of the Site have very narrow and steeply sloped off-channel areas. Broader off-channel areas with shallow benches (–10 to –30 ft CRD) occur from RM 1 to 4 along the outside curve of the river, including across the head of Multnomah Channel, between RM 6 and 8, and at the head of Swan Island Lagoon. A number of off-channel areas, such as Swan Island Lagoon, Willbridge Terminal, Willamette Cove, Terminal 4, and International Slip, vary widely in depth as a function of their history and current land use as actively dredged berths. Finally, several deep areas in the harbor extend from –60 to –80 ft CRD. These historical borrow areas were dredged to create the adjacent uplands; the two most extensive are in the eastern portion of the channel from RM 4.3 to 5 and RM 9.2 to 10. RI Map 3.1-13 shows the long-term bathymetric changes in the lower Willamette River between 1888 and 2001, illustrating the large-scale deepened, diverted, and filled areas.

The primary factors controlling river flow dynamics, sediment deposition and erosion, and riverbed character appear to be the river cross-sectional area and navigation channel width. The upstream boundary of the Site to Willamette Falls is narrower, more confined by bedrock outcrops, and faster flowing than the Portland Harbor reach. The river widens as it enters the Site and becomes increasingly depositional, most notably in the western portion of the river, until RM 7. From approximately RM 5 to RM 7, the river and navigation channel narrow; this reach is dominated by higher energy environments with little deposition. From RM 5 to approximately RM 2 the river widens again and becomes depositional, particularly in the eastern portion. Downstream of the Site, the river narrows as it turns and converges with the Columbia River. Multnomah Channel exits at RM 3, reducing direct discharge to the Columbia River.

Sediments in some locations may be resuspended and transported downstream during periods of high flow and from anthropogenic disturbances, such as vessel operations in the harbor. The degree of sediment deposition and movement is controlled largely by river hydrodynamics and

the sediment texture (grain size and organic matter content). Suspended silt and clay sediments are typically transported farther than sandy sediments under all flow conditions.

Bathymetric changes from 2002 to 2009 show the greatest net sediment accumulations occur where the channel is wide and flow velocities are reduced. Some areas of natural scour and dredging are also evident. Sediments in the scour areas are predominantly sand and appear to be relatively stable during low-flow conditions, but are mobilized when flow velocities are high. Nearshore and off-channel areas, such as Port terminals, and portions of Swan Island Lagoon and Willamette Cove, exhibit deposition. In other areas, such as RM 9 to 11E, within Swan Island Lagoon and Willamette Cove, RM 6 to 7W, and RM 5 to 7E, little elevation change and/or small-scale scour was observed. Sediment scour in some nearshore locations is due to ship traffic (wakes and prop wash). These activities appear to mix surface and subsurface sediments.

RI investigations characterized the physical nature of bedded sediments and their potential for movement within and through the lower Willamette River due to natural or anthropogenic forces. Physical sediment data included grain size, specific gravity, total solids, and total organic carbon (TOC). The interval from 0-30 centimeters (cm) below mud line (bml), the portion of the sediment column that has the potential to be disturbed or transported under typical annual conditions, was used to define surface sediments. Below 30 cm, the subsurface core samples showed major discontinuities in sediment texture and were used to define subsurface breaks. The grain-size data in surface sediment samples were used to create contour maps of surface sediment in the Site (RI Maps 3.1-3 and 3.1-4).

The sediment samples from the confluence with the Columbia River to Willamette Falls at RM 26 exhibited a large variety of sediment types ranging from sandy gravels to mud (silt and clay combined). The majority of the sediments over this reach were sands or muddy sands, with more coarse-grained sediments in relatively high-energy areas upstream of the Site (RM 11 to 26).

Overall, the surface and shallow subsurface sediment textures were consistent throughout the Site, suggesting relatively stable current energy regimes. There was, however, a subtle but perceptible widespread shift from finer-grained surface sediments to a slightly coarser-grained subsurface layer (from 81–100% fines to 61–80% fines) across much of the Site at different times of the year. This may reflect seasonal or inter-annual winnowing of the finer sediments from the sediment bed during higher flow periods and the subsequent long-term burial of the slightly coarser residual sediments.

Three areas showed coarser surface sediments overlying finer material, including the head of Swan Island Lagoon, the McCormick and Baxter/Willamette Cove area, and the area outside the entrance to Multnomah Channel and extending into the channel. Anthropogenic placement of fill at the head of Swan Island Lagoon by 1975 and the sand cap cover placed in the river and beach at the McCormick and Baxter Creosoting Company site in 2005 appear to explain this pattern in Swan Island Lagoon and around McCormick and Baxter/Willamette Cove, respectively.

### **6.2.5. Areas of Archeological or Historical Importance**

A cultural resource analysis concluded that there are possible archeological artifacts and areas of historical importance at the Site, but no gravesites were noted. Most of these artifacts are expected to be Native American protected objects. If Native American cultural items or gravesites are identified during construction, an inventory of such items will be compiled and items will be returned to the tribes.

If removal of cairn, burial, human remains, funerary objects, or other sacred objects takes place, re-interment will occur under the supervision of the appropriate Indian tribe. Any proposed excavation by a professional archaeologist of a Native American cairn or burial will require written notification to the State Historic Preservation Officer and consultation with the appropriate Indian tribe.

### **6.3. Sources of Contamination**

Historical industrial practices and releases of contaminants dating back to the early 1900s contributed to the majority of the observed chemical distribution in sediments within the Site. Contaminants from upland areas have entered the river system as direct discharges through storm water and waste water outfalls; from releases and spills from commercial operations occurring over the water, such as commodity transloading; and indirectly through overland flow, bank erosion, groundwater, and other nonpoint sources. In addition, contaminants from regional sources have reached the Site through inputs to surface water and sediment from upstream and through atmospheric deposition.

Contaminated media in Portland Harbor reflect the industrial, marine, commercial, and municipal practices for over 100 years in this active industrial, urban, and trade corridor, as well as agricultural activities in the Willamette Basin. Historical sources responsible for the existing contamination include, but are not limited to: ship building, repair, and dismantling; wood treatment and lumber milling; storage of bulk fuels and MGP waste; chemical manufacturing and storage; metal recycling, production, and fabrication; steel mills, smelters, and foundries; electrical production and distribution; municipal combined sewer overflows; and stormwater from industrial, commercial, transportation, residential, and agricultural land uses. Operations that continue to exist today include: bulk fuel storage, barge building, ship repair, automobile scrapping, recycling, steel manufacturing, cement manufacturing, operation and repair of electrical transformers (including electrical substations), and many smaller industrial operations. Locations of both current and historical major industrial operations in Portland Harbor are presented on RI Map 3.2-10 and RI Maps 3.2-13 through 3.2-21. Upstream sources within the broader Willamette River Basin contribute to contamination in sediment, surface water, and biota.

Ongoing pathways of contaminants to the Site include soil, storm water, groundwater, and river banks. Contaminants also reach the river via direct discharge through conveyance systems, atmospheric deposition, and overwater activities.

### **6.3.1. Direct Discharge**

Direct discharge of contamination occurs through conveyance systems, including municipal or other publicly owned drainage systems, privately owned and managed drainage systems, and sanitary/combined sewer systems. Today, many of these discharges are permitted under the National Pollutant Discharge Elimination System (NPDES) authorized by the Clean Water Act (CWA). Permitted discharges under the NPDES program include industrial wastes, stormwater runoff, and CSOs.<sup>4</sup> A survey conducted by the City of Portland in 2002 identified approximately 300 outfalls that discharge into the Site. These outfalls include discharge of stormwater, combined sanitary sewage and stormwater, and/or industrial wastewaters transported via a collection system, although most of the latter two are now routed through the sanitary sewer and no longer discharge directly to the waterway.

Historically, waste and other materials were used as fill and placed in or near the river to create more space for operations. Additionally, waste disposal in upland pits, lagoons, or lakes also directly discharged to the river through pipes, ditches, and creeks. In addition to direct discharge, contaminated soil, stormwater, and groundwater from past and current spills and leaks of hazardous substances infiltrated into these conveyance systems and was transported by direct discharge systems. Treated industrial wastes sometimes discharged to municipal and non-municipal storm drain systems.

### **6.3.2. Overland Transport**

Contaminated surfaces in upland areas can carry erodible soils and particulates directly to the river via sheet flow stormwater runoff (i.e., not through a conveyance system). Overland transport was likely to have been more important historically, prior to the development of extensive stormwater conveyance systems within the Site. Specific historical information on overland runoff is lacking for most upland properties in the Site.

### **6.3.3. Groundwater**

Groundwater in the greater Portland Basin within the Site generally flows towards the lower Willamette River, although the direction varies locally depending on the nature of subsurface materials, hydrostratigraphy, and proximity to the river. Near the river, tidal action can greatly alter groundwater flow directions, rates, and water quality. Groundwater may be contaminated by waste disposal practices, product storage practices, spills and leaks from pipes, storage tanks, industrial equipment, and process operations. Contaminated groundwater may enter directly into the Site via discharge through sediments or bank seeps, or it may infiltrate into storm drains/pipes, ditches or creeks that discharge to the river. Contaminant migration may occur as non-aqueous phase liquids (NAPLs) or as dissolved phase transport. Groundwater plumes

---

<sup>4</sup> CSO events are untreated discharges of combined stormwater and sanitary sewage from residential, commercial, and industrial sources that overflow from the sewer system into the river during heavy rainfall periods when the amount of stormwater and sewage exceeds the capacity of the collection system.

discharging or potentially discharging to the Site from upland areas is shown on Figure 6 in Appendix I.

#### **6.3.4. River Bank Erosion and Leaching**

Contaminated river bank soil, fill, or debris may release contaminants directly to the Site through bank erosion or leaching caused by groundwater and tidal action flux. Unprotected shoreline banks are susceptible to erosion by wind, river flows, wave action, tidal changes, and surface water runoff. Shoreline armoring and vegetation reduce bank erosion. Bank slope is also a factor since steeper banks are more susceptible to erosion.

#### **6.3.5. Atmospheric Deposition**

Contaminants are emitted to the air from point, mobile, biogenic, and area sources. Point sources include emissions from power plants, refineries, incinerators, stationary power sources, emission stacks, and liquid and petroleum storage tanks. Today, many point source air releases are permitted under the Clean Air Act (CAA). Mobile sources include emissions from motor vehicles and non-road equipment, such as railroads, marine vessels, and recreational off-road equipment. Biogenic sources include emissions from natural sources and area sources that are too small to be treated as point sources.

Contaminants emitted to the air may be transported over long distances, generally in the direction of the area's prevailing winds. They can be deposited from the atmosphere to land and water surfaces through wet deposition (precipitation) or dry deposition (as particles). Air pollutants can be deposited to water bodies through either direct or indirect deposition. Direct deposition occurs when contaminants are deposited onto the surface of a water body. Indirect deposition occurs when contaminants are first deposited on land and then transported to the water body via stormwater runoff.

#### **6.3.6. Overwater Activities**

Contaminants from overwater activities (e.g., sandblasting, painting, unloading, maintenance, repair, and operations) that may have dumped, sprayed, spilled, emitted or otherwise resulted in releases at or from riverside docks, wharfs, or piers; spills or releases from vessels (e.g., gray, bilge, or ballast water); and fueling station (e.g., barge to uplands) releases have the potential to impact the lower Willamette River.

#### **6.3.7. Upstream Watershed**

Upstream sources include, or have included, sewers, stormwater runoff, and direct discharge of industrial wastes; agricultural runoff; and aerial deposition of global or regional contaminants on the river water surface and drainage areas within the Willamette Valley.

#### **6.3.8. Summary of Known or Suspected Sources**

As part of the RI, summaries were prepared for 86 upland sites that were generally located within 0.5 mile of the river between RM 1.9 and 11.8 where DEQ-led investigations confirmed releases occurred; these sites are summarized on RI Table 4.2-2. The summaries are not an

exhaustive list of historic or current sources to the Site. DEQ's source control activities are summarized in the Portland Harbor Upland Source Control Summary Report, updated in April 2016 (DEQ 2016).

#### **6.4. Sampling Strategy**

Under the AOC, the LWG collected data for the RI during four major rounds of field investigations between 2001 and 2008 based on approved sampling plans to achieve data quality objectives. The field investigations began in 2001 and were conducted in the Initial Study Area (ISA), which was defined in the AOC Statement of Work and Programmatic Work Plan as RM 3 to RM 9. Round 2 sampling included RM 2 to RM 11. As the field studies progressed, the Site study area was expanded to RM 1.9 through RM 11.8, as well as a portion of the Multnomah Channel. Studies conducted by the LWG also included off-site areas downriver of the Site to the confluence with the Columbia River at RM 0, the Downtown reach from RM 11.8 to RM 16.6, and the upriver reach from RM 15.3 to RM 28.4. Figure 7 in Appendix I shows the areas of the river.

Surface and subsurface sediment, suspended sediment, surface water, stormwater, TZW/pore water, and biota/tissue samples were collected and analyzed, as summarized in RI Tables 2.3-2 through 2.3-10. More than 2,000 sediment, 200 surface water, and 300 TZW/pore water samples were collected. Biota samples included approximately 20 species, with hundreds of samples collected. The investigations were often timed around varying river stages, river flows, and storm events. In addition, groundwater and river bank sediment and soil samples were collected and analyzed by upland facilities under DEQ oversight. Additional data collected between 2008 and 2010 by two members of the LWG at the Arkema and Gasco facilities were also included in the final data set.

#### **6.5. Types of Contamination and Affected Media**

The primary contaminants detected at the Site and the affected media are summarized below. Additional details are included in the RI report (EPA 2016a).

##### **6.5.1. Contaminants of Concern**

The human health and ecological risk assessments concluded that contamination within the Site poses unacceptable risks to human health and the environment, with several contaminants of potential concern (COPCs). The risk assessments reduced the COPCs to a smaller number of COCs that contribute a significant amount of risk to the human and ecological receptors evaluated. COCs by media are listed in Tables 1 through 5 in Appendix II.

A subset of all COCs, called focused COCs, was developed in order to simplify analysis and evaluation of remedial alternatives for the Site. This subset was developed by evaluating co-location of all COCs, their toxicity, and significance in the risk assessments as well as other factors outlined in the RI. The focused COCs are described below, including their toxicity, mobility, and type of risks.

**PCBs** are human health and ecological COCs. They are manmade chemicals that were banned in the late 1970s. PCBs are mixtures of up to 209 compounds (or congeners). Some commercial PCB mixtures are known in the United States by an industrial trade name, Aroclor. Because they do not burn easily and are good insulating materials, PCBs were used widely as coolants and oils and in the manufacture of paints, caulking, and building material. PCBs are generally not mobile and stay in the environment for a long time. PCBs are classified as probable human carcinogens. Children exposed to PCBs may develop learning and behavioral problems later in life. PCBs are known to impact the human immune system and skin, especially in child receptors, and may cause cancer in people. Nursing infants can be exposed to PCBs in breast milk. PCBs also can bioaccumulate in fish, shellfish, and mammals. In birds and mammals, PCBs can cause adverse effects such as anemia and injuries to the liver, stomach, and thyroid gland. PCBs also can cause problems with the immune system, behavioral problems, and impaired reproduction.

**PAHs** are human health and ecological COCs. These chemicals are a major component of petroleum products or are formed during incomplete burning of coal, oil, gas, wood, or other substances. There are more than 100 different PAHs and they generally occur as complex mixtures. PAHs generally have limited mobility. PAHs are suspected human carcinogens with potential to cause lung, skin, and bladder cancers with occupational exposure. Animal studies show that certain PAHs affect the hematopoietic, immune, reproductive, and neurologic systems and cause developmental effects. They can cause inhibited reproduction, delayed emergence, sediment avoidance, and mortality. In fish, PAHs cause liver abnormalities and impairment of the immune system.

**Dioxins and furans** are human health and ecological COCs. They are byproducts of chemical manufacturing, combustion (either in natural or industrial settings), metal processing, and paper manufacturing. The dioxin compound (or congener) 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) is the most toxic form of dioxin and is a byproduct in the manufacture of herbicides such as “Agent Orange.” Dioxins and furans generally have limited mobility and stay in the environment for a long time. Toxic effects in humans include reproductive problems, problems in fetal development or early childhood, immune system damage, and cancer. Nursing infants can be exposed to dioxins and furans in breast milk. Dioxins and furans can bioaccumulate in fish, shellfish, and mammals. Animal effects include developmental and reproductive problems, hemorrhaging, and immune system problems.

**DDx**, which represents collectively DDT and its primary breakdown products dichlorodiphenyldichloroethane (DDD) and dichlorodiphenyldichloroethene (DDE), are human health and ecological COCs. DDT is a pesticide that was banned for use in the United States in 1972. It was used widely to control insects on crops and to control mosquitoes that spread malaria. These compounds have limited mobility. DDT is considered a possible human carcinogen. DDT and DDE are stored in the body’s fatty tissues. In pregnant women, DDT and DDE can be passed to the fetus. Nursing infants can be exposed to DDx in breast milk. Human exposure symptoms can include vomiting, tremors or shakiness, and seizures. Laboratory animal studies showed effects on the liver and reproduction. These compounds can accumulate in fish,

shellfish, and mammals, and can cause adverse reproductive effects such as eggshell thinning in birds.

### *Principal Threat Waste*

Principal threat waste (PTW) is defined as source material that includes or contains hazardous substances, pollutants, or contaminants that act as a reservoir for migration of contamination to groundwater, surface water, or air or that acts as a source for direct exposure. Further, principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur.

PTW was identified based on a  $10^{-3}$  cancer risk (highly toxic) or NAPL within the sediment bed (source material) and on an evaluation of mobility of contaminants in the sediment. “Reliably contained” was not used in identifying PTW but rather was used to determine how to address it through cleanup and whether there are concentrations of PTW that could be reliably contained. The following criteria were utilized to identify PTW:

- **Source Material:** NAPL has been identified in subsurface sediment offshore of the Arkema and Gasco facilities (RM 6 through RM 7.5) as globules or blebs of product in surface and subsurface sediment. However, areas of NAPL have not been fully delineated. Figure 8 in Appendix I identifies the general locations where NAPL was observed. NAPL observed offshore of the Arkema facility contained chlorobenzene with dissolved DDT. NAPL observed at the Gasco facility contained PAHs and other aromatic hydrocarbons.
- **Highly Toxic:** The following COCs were found at concentrations exceeding a  $10^{-3}$  risk level at the Site based on consumption of fish, using the assumptions and methodology presented in the baseline human health risk assessment (BHHRA) summarized in Section 8.1 and on Table 6 in Appendix II:
  - PCBs
  - Carcinogenic PAHs (cPAHs)
  - DDx
  - 2,3,7,8-TCDD
  - 2,3,7,8-tetrachlorodibenzofuran (TCDF)
  - 1,2,3,7,8-pentachlorodibenzo-p-dioxin (PeCDD)
  - 2,3,4,7,8-pentachlorodibenzofuran (PeCDF)
  - 1,2,3,4,6,7,8-hexachlorodibenzofuran (HxCDF)
- **PTW That Cannot be Reliably Contained:** A capping model was utilized in the FS (Appendix D) to identify PTW that cannot be reliably contained by a cap. Representative Site conditions and capping options were modeled to determine the maximum concentration of COCs in PTW material that would not exceed ambient water quality criteria (AWQC) in the sediment cap pore water after a period of 100 years. This assumption was used in developing the remedial alternative cost estimates in the FS

(Appendix G). Chlorobenzene, dioxins/furans, DDX, naphthalene, PAHs, and PCBs were modeled. The results are summarized in Table 7 in Appendix II. The areas where the model showed that PTW would not be reliably contained are presented on Figure 8 in Appendix I.

Surface sediment areas exceeding one or more PTW highly toxic concentration levels are presented on FS Figure 3.2-3. The PTW evaluation included only surface sediment, which poses the greatest risk of exposure given Site-specific conditions.

### **6.5.2. Contaminated Media**

The environmental media contaminated by Site-related contaminants include surface sediment (0 to 30 cm bml), subsurface sediment (below 30 cm bml), suspended sediment, surface water, groundwater, biota, and river banks. The surface sediment sample interval (0 to 30 cm bml) is designed to capture that portion of the sediment column that has the potential to be disturbed or transported under typical annual conditions. River banks are defined as areas from top of bank down to the river that may be contaminated along the shoreline next to contaminated in-river shallow areas. Contamination in these media is summarized in the following sections. Additional details are included in the RI report (EPA 2016a).

## **6.6. Nature and Extent of Contamination**

### **6.6.1. Surface and Subsurface Sediment**

Surface and subsurface sediment concentrations are presented in RI Maps 5.2-2 through 5.2-45 and RI Appendix D1.1 figures and RI Appendix D1.2 maps. COC concentrations, for both surface and subsurface sediment, are summarized in Table 1 in Appendix II. Contamination in subsurface sediment was identified as deep as 17 ft bml in the navigation channel and 19 ft bml in the sediment future maintenance dredge areas. In the intermediate region, the maximum depth of contamination was estimated to be 34 ft bml but most contamination was less than 10 ft. In the shallow region, the maximum depth of contamination was estimated to be 33.5 ft bml. These river areas are discussed in Section 10.1.2. Based on contaminant distribution trends, some general patterns emerged among subsets of different contaminants that reflect fate and transport processes at the Site, as well as the relative importance of regional versus Site sources. These patterns are discussed below.

**Sediment contaminant concentrations were greatest in nearshore areas.** Concentrations of contaminants were generally higher in nearshore and offchannel areas such as slips, embayments, and shallow areas, and near some known or suspected sources, as compared to sediments in the navigation channel, Multnomah Channel, and downstream areas.

**Organic contaminant concentrations were greater in subsurface sediments.** Concentrations of organic contaminants tended to be higher in subsurface sediments than in surface sediments. Concentrations of total PCBs, total DDX, total PAHs, hexachlorobenzene, total chlordanes, aldrin and dieldrin, gamma-hexachlorocyclohexane (Lindane), lead, and tributyltin (TBT) were higher in subsurface than in surface sediments, indicating that historical inputs were likely greater than current inputs. Subsurface contamination was detected as deep as 34 ft. In contrast, arsenic,

copper, chromium, mercury, and zinc did not have large concentration ranges and generally showed similar levels in surface and subsurface sediments. Other exceptions included areas where higher surface sediment concentrations appeared to be associated with ongoing Site sources, low rates of sediment deposition, and physical sediment disturbance (e.g., from boat scour).

**Regional inputs exhibited uniform concentrations across the area.** Contaminants that may have been derived predominantly from regional or upstream inputs showed widespread surface sediment distributions without distinct, isolated areas of higher concentrations. Examples of this were arsenic, chromium, and mercury, which occurred at relatively low concentrations throughout the Site with no apparent strong concentration gradients.

**Areas of high concentrations were present throughout the Site and generally were located near likely upland sources.** A number of contaminants exhibited relatively high sediment concentrations in distinct areas offshore of known or likely sources. These areas were separated by large areas with relatively lower concentrations lacking obvious concentration gradients. Contaminants that exhibited this trend included total PCBs, 2,3,7,8-TCDD, bis(2-ethylhexyl) phthalate (BEHP), butylbenzyl phthalate, pentachlorophenol (PCP), hexachlorobenzene, total chlordanes, Lindane, copper, zinc, and TBT.

**Some contaminants had areas of high concentrations that were more common in the lower (downstream) half of the Site.** Total DDx and total PAHs exhibited elevated concentrations in some locations of the river.

**Concentrations of certain metals were correlated to sediment grain size.** A comparison of metals concentrations to the distributions of percent fines in the Site showed that where sediments were comprised of less than 40% fines, chromium and copper concentrations were relatively low (above RM 10, between RM 5 and 7, and in the Multnomah Channel; RI Map 3.1-3). A similar, but less pronounced, correspondence existed between sandy sediments and zinc concentrations.

**Multiple contaminants co-occurred.** In most areas of the Site, multiple COCs are comingled. At all of the highest surface sediment concentration areas, more than one contaminant is found. This degree of contaminant co-occurrence reflects the variety of sources to the in-river portion of the Site and the history of upland Site development, including wastewater and stormwater conveyance systems and industrial and commercial activities.

### **6.6.2. Suspended Sediment**

While approximately 82% of the suspended sediment load passes through the Site, sediment traps were used to measure the suspended sediment load that would deposit within the Site. The areas where the highest concentrations of COCs were detected in sediment trap samples corresponded with areas with high concentrations of COCs in surface sediments, indicating the effect of erosion and resuspension of bottom sediment, the presence of current sources, or both. Suspended sediment contaminants in the Site had higher contaminant concentrations than

samples collected upstream of the Site (RI Tables 5.3-2 through 5.3-7). Sediment trap locations are provided on RI Map 2.1-15.

### **6.6.3. Surface Water**

Concentrations of contaminants in more than 300 surface water samples varied spatially and with river flow (Table 2 in Appendix II). Surface water concentrations in the Site were generally higher than those entering the upstream boundary of the Site (at RM 16) under all flow conditions. The highest contaminant concentrations in surface water within the Site were found near known sources where concentrations in sediment were also highest, such as the areas adjacent to the Gasco and Arkema facilities (RM 6 through RM 7.5W). Surface water samples collected at the downstream end of the Site (RM 2 and Multnomah Channel) showed higher concentrations of PCBs, dioxin/furans, DDx, BEHP, chlordanes, and aldrin than concentrations of these contaminants entering the Site from upstream. This pattern indicates that contamination from the Site is being transported to the Columbia River.

Surface water sample locations are shown on RI Map 2.1-18.

### **6.6.4. Groundwater**

Groundwater is a source of contamination to the Site. As part of the groundwater pathway assessment conducted for the RI, TZW and pore water samples in surface and nearsurface sediments were collected offshore of nine upland areas in the Site. Table 3 in Appendix II summarizes the COCs detected in TZW and pore water samples. Based on these efforts, a current complete groundwater pathway with influence on TZW and sediment chemistry was confirmed at four areas, groundwater migration was found to have no significant influence at four other areas, and groundwater effects could not be determined at one area.

RI Maps 5.5-1 through 5.5-6 show the nature and extent of known contaminated groundwater plumes currently or potentially discharging to the river within the Site. Contaminants detected in groundwater included, but were not limited to, PAHs, pesticides, cyanide, metals, and chlorinated and aromatic VOCs. Cleanup of contaminated groundwater is being managed by DEQ under a MOU with EPA, as discussed in Section 1. Currently, DEQ has identified multiple areas with groundwater contamination (Figure 6 in Appendix I and Table 3 in Appendix II).

TZW samples evaluated for ecological exposure were limited to those collected no deeper than 38 cm bml, which includes the biologically active zone.

### **6.6.5. Biota**

The biota data set includes fish and invertebrate samples collected during RI Rounds 1, 2, and 3, as well as samples collected by other parties (RI Table 2.3-8). Eleven fish species, four benthic invertebrate species, epibenthic communities, and fish stomach contents were sampled. RI Table 5.6-1 provides a summary of analyses for each species and tissue type. RI Table 2.3-10 provides the number of fish and invertebrates in each sample composite. The COCs detected in fish tissue (fillet and whole body) are in Table 4 in Appendix II.

Contaminants were detected in a majority of fish and invertebrate species sampled throughout the Site. Contaminant concentrations varied within and between different species, and concentrations in fish tissue were generally greater than in invertebrates. Concentrations of bioaccumulative compounds, such as PCBs and DDX, were often found at greater concentrations in organisms higher up the food chain and correlated with areas of elevated concentrations in sediment. Biota samples from within the Site exhibited greater concentrations for most contaminants than background biota samples that were collected from the upriver reaches and above Willamette Falls. Areas of elevated concentrations of some contaminants were found in resident species, reflecting high concentrations in nearby surface sediment and biological uptake by species with small home ranges.

Selected PCB and DDX results for resident fish species (smallmouth bass, brown bullhead, black crappie, and carp), adult Chinook salmon, and sturgeon are briefly summarized in Table 8 in Appendix II. These contaminants were selected because they commonly bioaccumulate and these species were evaluated in the BHHRA. Full results for all contaminants are included in RI Table 5.6-1.

#### **6.6.6. River Banks**

River banks are defined as the area from the top of bank down to the river. River bank data were collected under DEQ-led investigations. Contaminants detected in river bank material at levels that pose a risk to human health, the environment, or for recontamination to any implemented remedy, are summarized below by RM on the east and west sides of the river. Properties with known contaminated river banks are shown in Figure 9 in Appendix I and river bank contaminants are summarized on Table 5 in Appendix II).

##### *East Side of Willamette River*

**RM 2:** Evraz Oregon Steel Mill (Environmental Cleanup Site Information [ECSI] Site ID 141<sup>5</sup>) – Contaminants present in the river bank include PCBs and metals (arsenic, cadmium, chromium, copper, lead, manganese, and zinc).

**RM 3.5:** Schnitzer Steel Industries (ECSI Site ID 2355) – Results of soil samples collected under the docks along the south shore of the International Slip indicate that contaminants are PCBs and dioxins.

**RM 5.5:** MarCom South (ECSI Site ID 2350) – Further investigation of the nature and extent of contamination in the bank was conducted in 2012. Contaminants are PAHs and metals (arsenic, cadmium, chromium, copper, zinc).

**RM 7:** Willamette Cove (ECSI Site ID 2363) – River bank contaminants are PCBs, dioxins/furans, metals (lead, mercury, nickel, and copper), and PAHs.

**RM 8.5:** Swan Island Shipyard (ECSI Site ID 271) – Recent sampling results for indicate that contaminants include metals (arsenic, cadmium, chromium, copper, lead, mercury, and zinc),

---

<sup>5</sup> Site ID number is from DEQ's ECSI database.

PAHs, PCBs, and tributyltin. Contaminants in river bank soils in OU5 include metals (arsenic, copper, lead, and zinc), PAHs, and PCBs.

*West Side of Willamette River*

**RM 4:** Kinder Morgan Linnton Bulk Terminal (ECSI Site ID 1096) – Contaminants are petroleum constituents (benzene, toluene, ethylbenzene, xylenes, and PAHs) and metals (arsenic and lead).

**RM 6:** NW Natural/Gasco (ECSI Site ID 84) – Contamination associated with historical MGP waste are known to be located in the river bank. Contaminants include PAHs, gasolinerange hydrocarbons, diesel-range hydrocarbons, residual-range hydrocarbons, cyanide, and metals (zinc).

**RM 6 to RM 7:** Siltronic (ECSI Site ID 183) – Contamination associated with historical MGP waste is known to be present in the northern portion of the Siltronic river bank. River bank contaminants include PAHs, gasoline-range hydrocarbons, diesel-range hydrocarbons, residual-range hydrocarbon and cyanide and metals (zinc).

Burlington Northern Santa Fe Railway Company (BNSF) Railroad Bridge – Contamination associated with pesticide and herbicide releases from Rhone Poulenc and Arkema are known to be present in the river bank below and adjacent to the BNSF railroad bridge. River bank contaminants include dioxin/furans, metals (aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, potassium, selenium, silver, sodium, thallium, vanadium, zinc, insecticides (DDD, DDE, DDT, aldrin, alpha-hexachlorocyclohexane, alpha-chlordane, beta-BHC, cis-nonachlor, delta-BHC, dieldrin, endosulfan I, endosulfan II, endosulfan sulfate, endrin, endrin aldehyde, endrin ketone, gamma-BHC, gamma-chlordane heptachlor, heptachlor epoxide, hexachlorobutadiene, methoxychlor, mirex, oxychlordane, and transnonachlor), PCBs, semi-volatile organic compounds (SVOCs) (acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, benzoic acid, benzyl alcohol, BEHP, butylbenzylphthalate, chrysene, bibenzo(a,h)anthracene, dimethylphthalate, di-n-butylphthalate, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene and pyrene) (AMEC 2011).

**RM 7 to RM 8:** Arkema (ECSI Site ID 398) – River bank contaminants include DDT, dioxin/furans, PCBs, and metals (chromium and lead).

GS Roofing (ECSI Site ID 117) – River bank contaminants include total petroleum hydrocarbons and metals (arsenic, chromium, mercury, nickel, selenium).

**RM 8:** Hampton Lumber and Glacier NW (ECSI Site ID 1239) – River bank contaminants include steel mill slag fill.

**RM 9:** Gunderson (ECSI Site ID 1155) – River bank contaminants include metals (lead, nickel, and zinc), and PCBs.

**RM 10: Sulzer Bingham Pumps (ECSI Site ID 1235)** – River bank contaminants include PCBs and metals (arsenic, copper, lead, manganese, and zinc).

### **6.6.7. RCRA Hazardous Waste in Media**

RCRA characteristic hazardous waste criteria and disposal requirements are discussed in Section 3.4.9.1 in the FS (EPA 2016b) and in Sections 14 and 15 below. Based on current information, two areas of the Site have listed hazardous waste commingled in the sediment, either under RCRA hazardous waste listings or under Oregon’s hazardous waste law, offshore of the Arkema and Siltronic/Gasco facilities.

## **6.7. Computer Models Used For Fate and Transport**

### **6.7.1. Hydrodynamic and Sediment Transport Models**

Numerical hydrodynamic and sediment transport (HST) models were conducted to complement the empirical observations and gain a further understanding of physical system dynamics. The models were used to predict the potential impact of extreme (flood) events on Site sediment stability, particularly the potential for buried contaminated sediments to be re-exposed, and to better understand the complex hydrodynamics (i.e., the movement of surface water) of the lower Willamette River system. The models were also used to predict the bed elevation changes (i.e., the areas and magnitude of erosion and deposition in the Site) that would result from five different high-flow scenarios. A range of high-flow simulations were run because bed response can be a function of long-term hydrographic conditions that exist leading up to a flood event. The development and results of the HST model are discussed in the RI report (EPA 2016a).

### **6.7.2. Mass Transfer Model**

The RI also evaluated contaminant mass inputs from external sources and internal mass transfer mechanisms for a subset of contaminants within the Site on a Site-wide basis. Mass transfer models for these contaminants are presented on RI Figures 10.2-2, 10.2-5, 10.2-8, 10.2-11a, 10.2-14, 10.2-17, 10.2-20, 10.2-29, 10.2-32, 10.2-35, and 10.2-38. With all surface water, sediment, and sediment trap sample results taken together, there is evidence that contaminants from the Site are migrating downstream, especially from erosional areas, to either the Columbia River or Multnomah Channel and that the mass flux of contaminants exiting the downstream end of the Site in surface water is greater than the flux entering the Site.

External sources include upstream loading (via surface water and sediment bedload), “lateral” external loading such as stormwater runoff permitted discharges (point-source, non-stormwater), upland groundwater (contaminant plume transport to the river), atmospheric deposition (to the river surface), direct upland soil and river bank erosion, otherwise uncontaminated groundwater advection through contaminated subsurface sediments (chemical partitioning from subsurface sediment to pore water and advection to the surface sediment interval), and overwater releases.

Internal transfer mechanisms involve the transport of contaminant mass from one medium to another, but do not add new contaminant mass. Internal fate and transport mechanisms include sediment resuspension, transport, and deposition; solid/aqueous-phase partitioning; abiotic/biotic

transformation and degradation; biological uptake and depuration; groundwater advection; and sediment pore water exchange (chemical partitioning from surface sediment to pore water and advection to surface water). The hydrophobic nature of most of the organic contaminants means that they tend to preferentially partition to particulate organic matter.

### **6.7.3. HST Model Utilization**

The HST model results were evaluated as part of the FS. The primary purpose of the model was to evaluate remedial alternatives, support FS-level cap armoring design, and evaluate the potential for erosion of buried sediment contamination. Based on EPA's evaluation and additional evaluations conducted by Portland State University and USACE, a number of shortcomings in the modeling approach were identified, as discussed in more detail in Appendix H of the FS.

An evaluation of predicted versus measured changes in sediment bed evaluation concluded that the Portland Harbor HST model tends to over predict deposition, particularly in areas where erosion is measured. As a result, the utility of the contaminant fate and transport model developed for the Site to evaluate MNR is limited. In the FS, outcomes greater than  $t=0$  were not quantitatively evaluated using the HST model because the results are not quantitatively accurate and absolute or relative comparisons among quantitatively inaccurate outcomes is not helpful. However, quantitative evaluations of empirical data (e.g., trends in sediment deposition and fish tissue), where available, were undertaken.

A key element of the long-predictions of reductions in contaminant concentrations associated with natural recovery processes is the deposition of cleaner material resulting in declines in sediment concentrations. To further evaluate the ability of the HST model to accurately predict sediment deposition and erosion, a comparison of predicted vs. measured changes in bathymetry was performed on a sediment decision unit (SDU) basis. SDUs are separate areas of the Site that generally include the highest focused COC concentrations over one river mile segment. SDUs are used to evaluate the Site.

The overall approach involved comparing measured changes in sediment bed elevation to predicted changes for each model grid cell. Each model grid cell represented approximately one acre. SDUs range between 50 and 100 acres in size.

Measured changes in bathymetry were calculated using the results of the five bathymetric surveys conducted within Portland Harbor between 2002 and 2009. Measured changes in bathymetry were compared to modeled changes for the same time period. Changes in bathymetry were compared relative to the average elevation for each model grid using the approximate time mid-point of the bathymetric surveys. Comparisons between measured and predicted changes in sediment bed elevation were performed on a fate and transport model grid cell basis.

The evaluation indicated that the model predicted deposition the majority of the time. Erosion was predicted only within SDUs at RM 5.5E, RM 6.5E, RM 11E, and RM 6. However, measured changes in bathymetry indicated that some erosion was observed within every SDU. In addition, the plots did not correlate well with predicted and measured changes in sediment bed elevation.

Only in SDUs RM 5.5E, RM 6.5E, RM 11E, and RM 6 did the model predict erosion when deposition was observed. Conversely, the model predicted deposition when erosion was observed in every SDU.

As a result of the uncertainty over the accuracy of model predictions, the model was not used for FS-level evaluations.

## **7. CURRENT AND POTENTIAL FUTURE SITE AND RESOURCE USE**

### **7.1. Current Land and River Use**

Land use along the lower Willamette River in the harbor includes marine terminals, manufacturing, and other commercial operations, as well as public facilities, parks, and open spaces. RI Maps 3.2-1 and 3.2-8 illustrate land use zoning within the lower Willamette River as well as waterfront land ownership. The State of Oregon DSL owns certain submerged and submersible lands underlying navigable and tidally influenced waters, certain adjacent upland owners also own some submerged lands in the Site. The ownership of submerged and submersible lands is complicated and has changed over time.

The majority of the shoreline in the Site is currently zoned for industrial land use and is designated as an “Industrial Sanctuary” on the City of Portland Comprehensive Plan Map. Commercial and industrial use of the Site is discussed in Section 2.1. The federal navigation channel and its uses are also discussed in Section 2.1. The navigation channel is shown on Figure 1 in Appendix I.

In addition to industrial use zoning, other zoning designations for smaller portions of the Site include: open space (e.g., Cathedral Park and Willamette Cove); general employment (mixed use allowed although primarily an industrial-use focus); and multi dwelling residential (e.g., University of Portland). Residential areas on the west side include the Linnton neighborhood in pockets west of St. Helens Road between RM 4.3 and 5W, and in the mixed use Pearl District neighborhood in the vicinity of RM 12W. Most of the residential land use on the east side is above the bluff, except for the St. Johns neighborhood, which extends closer to the river between RM 5.7 and 6.8E.

In the Oregon State Administrative Rules (OAR) 340-041-0340, Table 340A, the designated beneficial use of the lower Willamette River includes, but is not limited to, hunting, fishing, boating, and water contact recreation. Recreational activities may include water skiing, occasional swimming, and waterfront recreation. The lower Willamette River is an important subsistence fishery for tribes and many minority communities in the region. Fishing for salmon, sturgeon, and other species is conducted throughout the Site, both by boaters and from locations along the banks.

The lower Willamette River provides Native American ceremonial and subsistence fisheries for Pacific lamprey (particularly at Willamette Falls) and spring Chinook salmon. Other culturally significant species include eulachon (smelt), and sturgeon. Native peoples also fish for a variety of other resident species, including mountain whitefish (*Prosopium williamsoni*), chiselmouth (*Acrocheilus alutaceus*), northern pikeminnow (*Ptychocheilus oregonensis*), peamouth

(*Mylocheilus caurinus*), and suckers (*Catostomus* spp.). Of land mammals historically found in the Portland Basin, deer and elk were the most frequently utilized by Native people. Native plants were, and continue to be, gathered for food and medicinal purposes. Tribes have reserved hunting, fishing (particularly salmon and sturgeon species) and certain gathering rights through Treaties with the United States. These activities provide food for Tribal families and cultural heritage knowledge and skills. Tribal uses of these resources continue today, but access to suitable patches of habitat continues to be both a challenge and an essential element of maintaining local Tribal cultural knowledge, practices, and traditions.

In addition, transients have been observed camping at various locations within the Site. The observation of tents and makeshift dwellings during RI sampling events confirmed that transients were present along some river bank areas. Therefore, they are expected to intermittently utilize this area in the future. Transients may also be using the lower Willamette River as a source of drinking water and they have reported harvesting and consuming various fish species as well as crayfish, mussels, and clams.

## **7.2. Groundwater and Surface Water Use**

### **7.2.1. Groundwater Use**

Groundwater is a critical natural resource providing domestic, industrial, commercial, and agricultural water supply; recreational uses; base flow for rivers, lakes, streams, and wetlands; and supply or habitat for livestock, wildlife, fish, or other aquatic life. Under OAR 340-040-0020, all groundwater of the state shall be protected from pollution that could impair existing or potential beneficial uses for which the natural water quality of the groundwater is adequate. Among the beneficial uses of groundwater, domestic water supply is recognized as the use that would usually require the highest level of water quality. High quality groundwater shall be maintained for present and future uses.

### **7.2.2. Surface Water Use**

Under OAR 340-041-0340, Table 340A, the designated beneficial uses of the lower Willamette River include, but are not limited to, hunting, fishing, boating, and water contact recreation. The state has promulgated numeric and narrative water quality standards to protect all of the designated uses. Another designated beneficial use of the lower Willamette River includes private and public domestic water supply. There are no known current or anticipated future uses of this part of the lower Willamette River within Portland Harbor as a private or public domestic water supply. According to the City of Portland, the primary public domestic water source for the City is the Bull Run watershed, which is supplemented by a groundwater supply from the Columbia South Shore Well Field. Upstream of Portland Harbor, the City of Wilsonville uses the Willamette River as a domestic water source following treatment, and the City of Sherwood began using the Willamette River in 2013.

## **7.3. Cultural and Recreational Resources**

It is important to note that locations that are and were used for hunting, fishing, and gathering, are likely locations for archeological sites containing important cultural artifacts. There may be

multiple strata of artifacts at some locations reflecting different eras of usage. If removal of cairn, burial, human remains, funerary objects, or other sacred objects takes place, re-interment will occur under the supervision of the appropriate Indian tribe. Proposed excavation by a professional archaeologist of a Native American cairn or burial requires written notification to the State Historic Preservation Officer and consultation with the appropriate Indian tribe. If cultural resources on, or eligible for, the national register are present, it will be necessary to determine, in consultation with the appropriate State Historic Preservation Office, if there will be an adverse effect to the resource and, if so, how the effect may be minimized or mitigated. A professional archaeologist must conduct any archaeological investigations at a site.

#### **7.4. Natural Resources**

##### **7.4.1. Upland and Aquatic Habitat**

Portland Harbor provides habitat for invertebrates, fishes, birds, mammals, amphibians, reptiles, and aquatic plants. Each group makes a contribution to the ecological function of the river, with its relative importance depending on its niche, its abundance, and its interaction with the physical environment. The invertebrate community living in the sediments provide important food for fish and other species in the Site. The biologically active zone of the Site that supports benthic communities is in the “shallow” sediment (less than 38 cm deep) and is generally 10 to 20 cm deep, based on sediment profiling imaging data gathered during the RI (Stiplin Environmental Associates 2002). The fish species found in the harbor include numerous species of resident fish (smallmouth bass, brown bullhead, black crappie, and carp); the river also serves as an important pathway for migration of anadromous species such as salmon, lamprey, and sturgeon. The lower Willamette River has been designated by the National Marine Fisheries Service (NMFS) as critical habitat for several salmon species that migrate through the Site. Fish in the harbor provide an important food resource for aquatic mammals, birds like osprey and bald eagle, and some larger fish species like northern pikeminnow and smallmouth bass.

Migratory and resident birds use the harbor. Resident birds include, but are not limited to, the bald eagle, Canada goose, mallard, spotted sandpiper, and great blue heron. Mammals that inhabit the Site include beaver, muskrat, raccoon, river otters, and California sea lion. Portland Harbor provides limited habitat for amphibians and reptiles, and most of the native amphibians prefer undisturbed areas that offer seasonal wetlands with emergent plants and shallow waters. Most local reptile species prefer wet vegetated upland habitats.

Aquatic plant communities are used by wildlife for refuge, nesting and breeding habitat, and they also provide food for herbivores and play a role in the cycling of nutrients. Habitat constraints in Portland Harbor, including muddy water and overwater obstructions that prevent the sun from reaching the bottom plus extensive bank armoring, limit the development of dense submerged and emergent plant communities in the Site.

##### **7.4.2. Threatened and Endangered Species**

The presence, or potential presence, of threatened and/or endangered species was evaluated in FS Appendix L; Tables L3-1 and L3-2 summarize the listed species that have the potential to live

within the Site. The lower Willamette River has been designated by NMFS as critical habitat for Lower Columbia River Chinook salmon, Lower Columbia River steelhead, Upper Willamette River Chinook salmon, Upper Willamette River steelhead (70 Federal Register 52630), and is proposed critical habitat for Lower Columbia River Coho salmon (78 Federal Register 2726). The Site provides migration and rearing habitat, and both adult and juvenile salmonids are common in the lower Willamette River during various times of the year. Adults are present during their upriver spring migrations, whereas, juvenile salmonids can be found in the lower Willamette River yearround. The critical habitat designations identified above in the Federal Register indicate that freshwater rearing sites and migration corridors, such as provided by the Site, are essential to the conservation of the listed salmonid species.

### **7.5. Potential Future Land, River and Resource Use**

The potential future land use and resource use of the Site is expected to be the same as the current use but if land uses change, the remedy will be adjusted considering the new use.

## **8. SUMMARY OF SITE RISKS**

As part of the RI/FS, baseline human health and ecological risk assessments were conducted to estimate the current and future effects of contaminants in sediments (from human-use beaches and in-river sediment collected from less 30 cm depth between the bank and the navigation channel), surface water, groundwater seeps, and fish tissue on human health and the environment. A baseline risk assessment is an analysis of the potential adverse human health and ecological risk of releases of hazardous substances from a site in the absence of any actions or controls to mitigate such releases, under current and future land and resource uses. The baseline risk assessment includes a BHHRA and a baseline ecological risk assessment (BERA). They provide the basis for taking action and identify the COPCs and exposure pathways that the remedial action should address. The BHHRA and BERA are included in the RI report in Appendices F and G, respectively. This section of the ROD summarizes the results of the baseline risk assessments.

### **8.1. Human Health Risks**

The Site-specific BHHRA estimated cancer risks and noncancer health hazards from exposures to a set of chemicals in sediments (both beach and in-river), surface water, groundwater seeps, and fish tissue from samples collected at the Site.

A four-step process is used for assessing Site-related human health risks:

- **Hazard identification** uses the analytical data collected to identify the COPCs at the Site for each medium based on such factors as toxicity, frequency of occurrence, fate and transport of the contaminants in the environment, concentration, mobility, persistence, and bioaccumulation.
- **Exposure assessment** evaluates the different exposure pathways through which people might be exposed to contaminants based on media-specific contaminant concentrations, the frequency and duration of these exposures, and the pathways by which humans are

potentially exposed (e.g., consumption of contaminated fish and shellfish, dermal contact with contaminated sediment, and ingestion of, and dermal contact with, contaminated surface water or groundwater).

- **Toxicity assessment** determines the types of adverse health effects associated with chemical exposures and the relationship between magnitude of exposure (dose) and severity of adverse effects (response).
- **Risk characterization** summarizes and combines outputs of the exposure and toxicity assessments to provide a quantitative assessment of site-related cancer risks and noncancer hazards. The risk characterization also identifies contamination with concentrations that exceed acceptable levels, identified in the National Contingency Plan (NCP) and EPA guidance as an excess lifetime cancer risk greater than  $10^{-6}$  to  $10^{-4}$  (1 in 1,000,000 to 1 in 10,000) or a noncancer Hazard Index (HI) greater than 1. Contaminants at these concentrations are considered COCs and are typically those that will require remediation at a site. This section includes a discussion of the uncertainties associated with these risks.

#### 8.1.1. Hazard Identification

The BHHRA identified COPCs present in beach sediment, in-river sediment, surface water, groundwater seeps, fish, and shellfish within the Site. The data used in the BHHRA by medium are summarized below:

- **Beach sediment:** Composite beach sediment samples that were collected from designated human use areas within the Site.
- **In-river sediment:** In-river sediment (i.e., sediment not located on a beach) samples that were collected from the upper 30 cm of the sediment bed between the bank and the navigation channel.
- **Surface water:** Surface water data collected from the Site as well as Multnomah Channel.
- **Groundwater seep:** Data from Outfall 22B, which discharges in a potential human use area. However, samples collected from this outfall as part of a stormwater sampling event were excluded.
- **Fish tissue:** Composite samples, both whole body and fillet with skin (fillet without skin samples were analyzed for mercury only), of target resident fish species (smallmouth bass, brown bullhead, black crappie, and common carp). Composite samples of adult Chinook salmon (whole body, fillet with skin, and fillet without skin), adult lamprey (whole body only), and sturgeon (fillet without skin only) were also included in the evaluation of consumption by Tribal members.
- **Shellfish tissue:** Composite samples of crayfish and clam tissue, depurated and undepurated.

COPCs were selected for quantitative evaluation in the BHHRA by comparing the Site characterization and risk assessment analytical data to risk-based screening values. If the maximum detected concentration of a chemical exceeded its appropriate risk-based screening level or if a risk-based screening level was not available, the contaminant was selected as a COPC. The BHHRA estimated risks for all COPCs. Consistent with EPA risk assessment guidance (EPA 1989, 1991), the findings of the BHHRA were used to narrow the list of COPCs to a shorter list of COCs. COCs are those contaminants estimated to pose an unacceptable risk and, therefore, need to be addressed in the FS. BHHRA Table 7-1 shows chemicals potentially showing unacceptable risk by medium. COCs for both human health and ecological receptors are summarized on Tables 1 (sediment), 2 (surface water), 3 (pore water and TZW), 4 (fish tissue), and 5 (river bank soil) in Appendix II.

### **8.1.2. Exposure Assessment**

Consistent with EPA risk assessment guidance (EPA 1989, 1991), the BHHRA serves as a baseline and assumes no remediation or institutional controls to mitigate or remove hazardous substance releases. Cancer risks and noncancer HIs were calculated based on estimates of reasonable maximum exposures (RME) and central tendency exposures (CTE) to describe the magnitude and range of exposures that might be incurred by receptor groups under current and future conditions at the Site. The RME is defined as the highest exposure that is reasonably expected to occur at a site, whereas the CTE is intended to reflect central (more typical) estimates of exposure. The objective of providing both the RME and CTE exposure cases is to bound the risk estimates, although decisions are based on the RME, consistent with the NCP.

#### **8.1.2.1. Conceptual Site Model**

The CSM describes potential contaminant sources, transport mechanisms, potentially exposed populations, exposure pathways, and routes of exposure. The CSM is presented on Figure 2 in Appendix I.

#### **8.1.2.2. Identification of Potentially Exposed Populations**

Populations were identified that could be exposed to contaminants through a variety of activities consistent with current and potential future uses of the Site. These include people who work along and on the river; people who use the river for recreational purposes; professional divers engaged in routine inspections, maintenance, or repair activities; and people who may live along the shoreline for a limited time (2 years was assumed). Use of the river as a drinking source was also considered as a future use because it is a designated beneficial use for the river. Many people catch fish in the lower Willamette River for recreation and as a supplemental or primary food source. Shellfish are also collected and consumed by people. The river provides a ceremonial and subsistence fishery for some Tribal members, who typically consume more fish than the general public. Fish are an important food source as well as an integral part of the tribes' cultural, economic, and spiritual heritage.

As a result of all these activities, exposure to contaminants at the Site can occur through direct contact with contaminated beaches, sediment, and surface water through incidental or intentional

ingestion (for example, drinking water) or through skin contact with the contaminated sediment or water. Exposure to contaminants in groundwater can occur after it discharges into the river. Because of the persistent nature of many of the contaminants, they can bioaccumulate through the food chain, and the resulting concentrations in fish can be much higher relative to concentrations in water and sediment, and exposure can occur through consumption of fish and shellfish caught from the river. Finally, bioaccumulative contaminants can partition into breast milk; thus, infants can be exposed to these contaminants through breastfeeding. The specific populations and exposure pathways evaluated in the BHHRA were as follows:

- **Dockside workers:** Direct exposure via incidental ingestion and dermal contact with beach sediments.
- **In-river workers:** Direct exposures to in-river sediment.
- **Transients:** Direct exposure to beach sediment, surface water for bathing and drinking water scenarios, and groundwater seeps. This group includes the houseless population.
- **Recreational beach users:** Direct exposure to beach sediment and surface water while swimming.
- **Tribal fishers:** Direct exposure to beach or in-river sediments and consumption of migratory and resident fish.
- **Recreational and subsistence fishers:** Direct exposure to beach or in-river sediments and consumption of resident fish and shellfish.
- **Divers:** Direct exposure to in-river sediment and surface water.
- **Domestic water user:** Direct exposure to untreated surface water potentially used as a drinking water source in the future.
- **Infant consumption of human breast milk:** Exposure to certain persistent and bioaccumulative contaminants (PCBs, DDX, dioxins and furans, and polybrominated diphenyl ether) via nursing infants of dockside and in-river workers; divers; and recreational, subsistence, and Tribal fishers.

#### 8.1.2.3. Exposures and Exposure Point Concentrations

Exposures were evaluated on a Site-wide basis as well as on more localized spatial scales, as appropriate, for each exposure scenario. Exposure to beach sediment was assessed per beach, and exposure to groundwater seeps was assessed per seep. Exposure to in-river sediment, surface water, and fish and shellfish tissue was assessed on both localized and Site-wide scales. Except where specifically noted, the exposure assumptions used in the BHHRA were applied uniformly to all of the Site and may or may not be applicable at specific Site locations, depending on factors not specifically addressed in the BHHRA.

Exposure point concentrations (EPCs) were calculated to represent the average concentration contacted over the duration of the exposure. Consistent with EPA guidance, the 95% upper confidence limit (UCL) on the arithmetic mean was used to represent the average concentration.

The maximum reported concentration was used in instances where there were insufficient data to calculate a UCL or the calculated UCL was greater than the maximum reported value. EPC tables from the BHHRA are included in Appendix III.

#### 8.1.2.4. Estimation of Chemical Intakes

The amount of each chemical incorporated into the body is defined as the dose and is expressed in units of milligrams per kilogram per day (mg/kg-day). The dose is calculated differently when evaluating carcinogenic effects than when evaluating noncarcinogenic effects.

For non-occupational scenarios where exposures to children are considered likely, exposures to both adult and child were evaluated. Children often exhibit behavior such as outdoor play activities and greater hand-to-mouth contact, which can result in greater exposure than for a typical adult. In addition, children have a lower overall body weight relative to the predicted intake. As cancer risks are averaged over a lifetime, they are directly proportional to the exposure duration. Accordingly, a combined exposure from childhood through adult years was evaluated, where appropriate, to account for the increased relative exposure and susceptibility associated with childhood exposures.

In general, Superfund exposure assessments assess RME by using a combination of 90th or 95th percentile values for contact rate, exposure frequency, and duration, and 50th percentile values for other variables. CTE estimates are done using average or median values for all variables. Receptor exposures for RME and CTE scenarios are included in BHHRA Tables 3-21 through 3-25.

The fish consumption rates used in the risk assessment were developed by information gathered from published studies that evaluated the consumption habits of people in the Portland area, as well as consumption rates of the general public. Local recreational fishers generally prefer non-resident fish species such as spring Chinook salmon, steelhead trout, Coho salmon, shad, and white sturgeon. Immigrants from Eastern Europe and Asia, African-Americans, and Hispanics are most likely to eat resident fish from the lower Willamette River either as a supplemental or primary dietary source. The most commonly consumed resident species for these populations are smallmouth bass, brown bullhead, black crappie, carp, and catfish. Because different people consume different quantities of resident fish, three different consumption rates were evaluated to examine the range of exposures for non-Tribal fish consumption patterns. Tribal populations consume both resident and non-resident fish species.

A consumption rate of 17.5 grams per day (g/day) of resident fish (approximately two 8-ounce meals per month) was used to represent a CTE value for recreational fishers, and 49 g/day (approximately six and one-half 8-ounce meals per month) was selected as representing the higher-end consumption rate for this group. A rate of 142 g/day (nineteen 8-ounce meals per month) was used for “subsistence fishers,” a term used for people who consume fish as a substantial portion of their diet. Table 9 in Appendix II summarizes the RME and CTE assumptions for recreational and subsistence fishers. This higher consumption rate was used on a Site-wide basis and assumed consumption of all the types of resident fish (representative species were smallmouth bass, brown bulhead, black crappie, and carp).

Risks to recreational fishers were evaluated on both a Site-wide and localized river mile scale. Because contaminant concentrations in migratory fish are not all related to the Site, only consumption of “resident” fish was considered. The Site-wide evaluation assumed the same diet of resident species. The river mile evaluation used only the data for smallmouth bass, the only species with contaminant data on that smaller scale, to represent contaminant concentrations in all resident fish species.

Fish consumption by Tribal members was evaluated assuming an overall rate of 175 g/day (approximately twenty-three 8-ounce meals per month), also based on the Columbia River Inter-Tribal Fish Commission (CRITFC) 1994 survey. However, this rate is based on a multi-species diet that includes both resident and migratory fish (Table 10 in Appendix II). Data from the CRITFC survey indicate that approximately 50% of the reported consumption consists of salmon, lamprey, and sturgeon. The BHHRA evaluated risks due to consumption of fish for Tribal members assuming a mix of migratory and resident fish. In order to assess the risk associated with contamination within the Site, consumption of resident fish by Tribal consumers was evaluated assuming that 50% of their fish diet, or a rate of 87 g/day, was resident fish and the remainder of the diet was assumed to be migratory fish (salmon, lamprey, and sturgeon). Consistent with the range of Tribal practices, risks were evaluated assuming fillet-only consumption as well as using the entire fish in preparing meals.

Consumption rates for children for the recreational, subsistence, and Tribal exposure estimates were estimated to be 42% of the rates for adults based on the CRITFC 1994 survey and were used to estimate noncancer hazards, as children are generally more sensitive to the noncancer effect of exposure to contaminants.

### **8.1.3. Toxicity Assessment**

The toxicity assessment determines whether exposure to COCs may result in adverse health effects in humans and the relationship between the magnitude of exposure (dose) and incidence and/or severity of adverse effects (response). For risk assessment purposes, chemicals are generally separated into categories based on whether a chemical exhibits carcinogenic or noncarcinogenic health effects. As appropriate, a chemical may be evaluated separately for both effects. Noncancer effects are evaluated using a reference dose (RfD), which is the dose below which adverse health effects are not expected. Carcinogenic effects are assessed using the cancer slope factor (SF), which is typically expressed in units of mg/kg-day. The SF represents an upper bound estimate on the increased cancer risk. SFs are generally accompanied by a weight of evidence descriptor, which expresses the confidence as to whether a specific chemical is known or suspected to cause cancer in humans.

#### **8.1.3.1. Cancer Assessment**

Potential cancer effects are expressed as the probability that an individual will develop cancer over a lifetime based on the exposure assumptions described in Section 8.1.2. The cancer SF is a plausible upper bound estimate of carcinogenic potency used to calculate cancer risk from exposure to carcinogens by relating estimates of lifetime average chemical intake to the

incremental probability of an individual developing cancer over a lifetime. SFs for assessing oral and dermal exposure are presented in BHHRA Table 4-1 in Appendix III.

#### 8.1.3.2. Noncancer Assessment

Noncancer health effects were evaluated using RfDs. An RfD is an estimate of a daily oral exposure for a given duration to the human population (including susceptible subgroups) that is likely to be without an appreciable risk of adverse health effects over a lifetime. Chronic RfDs are specifically developed to be protective against long-term exposure to COCs. The RfDs utilized to assess noncancer effects are presented in BHHRA Table 4-2 in Appendix III.

#### 8.1.4. Risk Characterization

Risk characterization integrates the information from the exposure assessment and toxicity assessment, using a combination of qualitative and quantitative information. Risk characterization involves estimating the magnitude of the potential adverse health effects associated with the COCs. It also involves making judgments about the nature of the human health threat to the defined receptor populations. The risk characterization combines the results of the dose-response (toxicity assessment) and exposure assessment to calculate cancer risks and noncancer health hazards. In accordance with EPA's guidelines, this assessment assumes that the effects of all contaminants are additive through a specific pathway within an exposure scenario.

For carcinogens, risks are generally expressed as the incremental probability of an individual developing cancer over a lifetime as a result of exposure to the carcinogen. Excess lifetime cancer risk (a unitless probability of an individual's developing cancer) is calculated by multiplying the chronic daily intake averaged over 70 years (mg/kg-day) and the SF (per mg/kg-day).

These risks are probabilities that usually are expressed in scientific notation (e.g.,  $1 \times 10^{-6}$ ). An excess lifetime cancer risk of  $1 \times 10^{-6}$  indicates a probability that the RME individual has a 1 in 1,000,000 chance of developing cancer as a result of site-related exposure. This is referred to as an "excess lifetime cancer risk" because it would be in addition to the risks of cancer individuals face from other exposures. The upper-bound excess lifetime cancer risks derived in this assessment are compared to the risk range of  $10^{-4}$  to  $10^{-6}$  established in the NCP. EPA's goal of protection for cancer risk is  $10^{-6}$ , and risks greater than  $10^{-4}$  typically will require remedial action.

The potential for noncancer health effects is estimated by comparing the average daily dose (ADD) of a chemical for adult, adolescent, and child with the RfD for the specific route of exposure (e.g., oral). The ratio of the intake to reference dose (ADD/RfD) for an individual chemical is the hazard quotient (HQ). When an RfD is available for the chemical, these ratios are calculated for each chemical that elicits a noncancer health effect. Typically, chemical-specific HQs are summed to calculate an HI value for each exposure pathway. EPA's goal of protection for noncancer health effects is an HI equal to 1. When the HI exceeds 1, there may be a concern for health effects. This approach can result in a situation where HI values exceed 1 even though no chemical-specific HQs exceed 1 (i.e., adverse systemic health effects would be expected to

occur only if the receptor were exposed to several contaminants simultaneously). In this case, chemicals are segregated by similar effect on a target organ, and a separate HI value for each effect/target organ is calculated. If any of the separate HI values exceed 1, adverse, noncancer health effects are possible. It is important to note, however, that an HI exceeding 1 does not predict a specific disease.

#### 8.1.4.1. Risk Characterization Results

The risk characterization results are presented below by receptor and exposure scenario; full results are included in BHHRA Tables 5-87 through 5-111 in Appendix III.

##### *Dockside Workers*

Risks to dockside workers were estimated separately for each of the eight beaches designated as potential dockside worker use areas. The RME estimated cancer risks ranged from  $7 \times 10^{-7}$  to  $5 \times 10^{-5}$  at all beach areas and the RME HIs ranged from 0.005 to 0.01 for adults. For breast feeding infants estimated RME HIs ranged from 0.01 to 1.

##### *In-River Workers*

In-river sediment exposure by in-river workers was evaluated in half-mile increments along each side of the river. The estimated RME cancer risks ranged from  $9 \times 10^{-8}$  to  $2 \times 10^{-5}$  at all river mile segments and the RME HIs for adults ranged from 0.001 to 0.2 at all locations. The RME HIs for breast feeding infants ranged from 0.003 to 2 at RM 7W due to dioxins and furans.

##### *Transients*

Risks to transients were estimated separately for each beach designated as a potential transient use area as well as for the use of surface water as a source of drinking water and for bathing. Year-round exposure to surface water was evaluated for individual stations: Willamette Cove, Multnomah Channel, and for four transects grouped together to represent Site-wide exposure. The RME cancer risk estimates for beach sediment ranged from  $1 \times 10^{-7}$  to  $4 \times 10^{-7}$  for all locations and the RME HIs ranged from 0.04 to 0.1. Estimated RME cancer risks associated with surface water exposures ranged from  $6 \times 10^{-7}$  to  $9 \times 10^{-7}$ , and RME HIs ranged from 0.05 to 0.3. Estimated RME cancer risk associated with a groundwater seep at Outfall 22 was  $3 \times 10^{-9}$  and the RME HI was 0.006.

##### *Divers*

Commercial divers were evaluated for exposure to surface water and in-river sediment assuming the diver was wearing either a wet or a dry suit. In-river sediment exposure by divers was evaluated in half-mile exposure areas for each side of the river and on a Site-wide basis. Risks associated with exposure to surface water were evaluated for four individual transect stations and at single-point sampling stations grouped together in one-half mile increments per side of the river.

For divers wearing wet suits, the estimated RME cancer risks associated with exposure to in-river sediments ranged from  $9 \times 10^{-8}$  to  $3 \times 10^{-5}$  at all half-mile river segments and the HIs ranged

from 0.001 to 0.1. The RME HI for indirect exposure to breast feeding infants of adult divers ranged from 0.004 to 2 at RM 8.5W due to PCBs. The estimated RME cancer risks associated with exposure to surface water ranged from  $1 \times 10^{-8}$  to  $1 \times 10^{-5}$  for all half-mile river segments and the RME HIs ranged from 0.0001 to 0.003.

For divers wearing dry suits, the estimated RME cancer risk associated with exposure to in-river sediments ranged from  $3 \times 10^{-8}$  to  $1 \times 10^{-5}$  and HIs ranged from 0.0002 to 0.2. The RME HIs for indirect exposure to breast feeding infants of adult divers ranged from 0.001 to 0.3. Surface water estimated RME cancer risk ranged from  $1 \times 10^{-8}$  to  $2 \times 10^{-6}$  at all half-mile river segments and the RME HIs ranged from 0.0001 to 0.002 for adults.

#### *Recreational Beach Users*

Risks associated with exposure to beach sediment were evaluated separately for each beach designated as a potential recreational use area, and exposure to surface water was evaluated using data collected from three transect locations and three single-point locations at Cathedral Park, Willamette Cove, and Swan Island Lagoon. Estimated RME cancer risks associated with exposure to beach sediments ranged from  $2 \times 10^{-5}$  to  $5 \times 10^{-5}$  and RME HIs ranged from 0.1 to 0.4. Estimated RME cancer risks associated with surface water exposure ranged from  $6 \times 10^{-8}$  to  $7 \times 10^{-8}$  at all recreational beach areas. The RME HI for surface water was 0.001 at 3 locations. Indirect exposures to infants via breastfeeding were not evaluated.

#### *Recreational/Subsistence Fishers*

Recreational and subsistence fishers were evaluated assuming direct exposure to contaminants in sediment and via consumption of fish and shellfish. Exposures associated with beach sediment were assessed at individual beaches designated as potential transient or recreational use areas. In-river sediment exposures were evaluated on a one-half river mile basis per side of the river and as an averaged, Site-wide evaluation. Sediment exposures were further assessed as CTE and RME evaluations and assuming either a low- or a high-frequency rate of fishing.

Estimated RME cancer risks associated with beach sediments with both low- and high-frequency fishing to beach sediment ranged from  $4 \times 10^{-7}$  to  $6 \times 10^{-6}$  and RME HIs ranged from 0.01 to 0.05. Estimated RME cancer risks associated with in-river sediment with both low- and high-frequency fishing ranged from  $2 \times 10^{-7}$  to  $8 \times 10^{-5}$  and RME HIs ranged from 0.001 to 2 at RM 7W. The CTE HIs for in-river sediment ranged from 0.0001 to 0.01. For RME indirect exposure to infants breastfeeding, the estimated HIs ranged from 0.003 to 2 at RM 8.5W. The CTE indirect exposure to infants breastfeeding ranged from 0.0002 to 0.04 at RM 8.5W. Indirect exposure to contaminants in beach sediment via breastfeeding infants was not evaluated.

Consumption of resident fish species was evaluated on a river mile basis using smallmouth bass data as a surrogate for all fish consumed. Consumption of fish was also evaluated over the entire Site, assuming a diet consisting of equal proportions of common carp, brown bullhead, back crappie, and smallmouth bass. Consumption on a river mile basis was evaluated only for recreational fishers; consumption averaged over the entire Site was evaluated for both recreational and subsistence fishers. With the exception of RM 5, RME estimated cancer risks on

a river mile basis were all greater than  $1 \times 10^{-4}$ , ranging from  $9 \times 10^{-4}$  to  $1 \times 10^{-3}$ . River miles exhibiting the highest estimated RME risks are RM 2 ( $2 \times 10^{-4}$ ), RM 4 ( $3 \times 10^{-4}$ ), RM 7 ( $6 \times 10^{-4}$ ), Swan Island Lagoon ( $6 \times 10^{-4}$ ), RM 9 ( $2 \times 10^{-4}$ ), and RM 11 ( $1 \times 10^{-3}$ ). Site-wide RME risks for recreational and subsistence fishers were  $4 \times 10^{-3}$  and  $1 \times 10^{-2}$ , respectively. CTE cancer estimates ranged from  $3 \times 10^{-5}$  to  $4 \times 10^{-4}$ , with the highest levels at RM 7, Swan Island Lagoon, and RM 11. The Site-wide CTE estimate for recreational fishers was  $1 \times 10^{-3}$ . Risks are primarily due to PCBs.

For recreational fishers, the RME HIs ranged from 6 to 100 by river mile with the highest RME HIs at RM 4, RM 7, Swan Island Lagoon, and RM 11. Site-wide RME HIs for recreational and subsistence fishers were 300 and 1,000, respectively. The CTE HI estimates for recreational fishers ranged from 2 to 30, with a Site-wide HI of 100. Risks are primarily due to PCBs.

For infant indirect exposure via breastfeeding, the RME HIs ranged from 30 to 1,000 on a river mile basis, with a Site-wide HI of 4,000. River miles exhibiting the greatest RME HIs were: RM 2 (200), RM 4 (200), RM 7 (200), Swan Island Lagoon (600), and RM 11 (1,000). The CTE estimates ranged from 10 to 500 when assessed on a river mile scale and was 2,000 on a Site-wide basis. The RME HI for subsistence fishers was 10,000. The majority of the hazard estimate is attributable to PCBs.

#### *Subsistence Fishers*

For subsistence fishers, risks from consumption of clams and crayfish were evaluated. Estimated RME cancer risks associated with consumption of undepurated clams by subsistence fishers ranged from  $4 \times 10^{-5}$  to  $7 \times 10^{-4}$  with estimates greater than  $1 \times 10^{-4}$  at 10 of the 22 river mile sections evaluated. The estimated RME risk Site-wide is  $4 \times 10^{-4}$ . Carcinogenic PAHs pose the highest risks at RM 5W and 6W, while PCBs pose the highest risks in Swan Island Lagoon and RM 11. Carcinogenic PAHs and PCBs pose the highest risks on a Site-wide basis. Estimated CTE cancer risks ranged from  $6 \times 10^{-6}$  to  $1 \times 10^{-4}$ , with a Site-wide estimate of  $7 \times 10^{-5}$ . Risks based on depurated clams were estimated at RM 1E, 2W, 10W, 11E, and 12E, and none of the estimated CTE or RME cancer risks were greater than  $1 \times 10^{-4}$ .

The estimated RME HIs associated with consumption of undepurated clams by subsistence fishers ranged from 1 to 30 with estimates greater than 1 at 20 of the 22 river mile sections evaluated. The Site-wide RME HI was 9. The estimated CTE HIs ranged from 0.2 to 7, with a Site-wide CTE estimate of 2. Risks are primarily due to PCBs.

For indirect exposure to infants via breastfeeding, RME HIs ranged from 10 to 800 on a river mile basis, with a Site-wide RME estimate of 200. CTE HIs ranged from 2 to 200 with a Site-wide CTE estimate of 30. Risks are primarily due to PCBs.

For consumption of crayfish by subsistence fishers, the RME cancer estimates ranged from  $6 \times 10^{-6}$  to  $3 \times 10^{-4}$  and a Site-wide RME estimate of  $3 \times 10^{-4}$ . Risks are primarily due to PCBs. The highest estimates were at RM 7W and RM 11E. The estimated CTE cancer risks ranged from  $1 \times 10^{-6}$  to  $6 \times 10^{-5}$  with a Site-wide CTE estimate of  $6 \times 10^{-5}$ .

For consumption of crayfish by subsistence fishers, the estimated RME HIs ranged from 0.5 to 6 with a Site-wide RME estimate of 10. The estimates greater than 1 were at 7 of the 32 individual

stations, primarily due to PCBs. The CTE HI estimates ranged from 0.08 to 3 with a Site-wide CTE estimate of 2.

For indirect exposure to infants via breastfeeding, RME HIs ranged from 0.1 to 400 with a Site-wide RME estimate of 200, primarily due to PCBs. HIs greater than 1 were estimated at 23 of the 32 stations evaluated. The CTE HIs ranged from 0.001 to 70 with a Site-wide CTE estimate of 40.

A summary of risk results for recreational and subsistence fishers is shown on Table 11a in Appendix II.

### *Tribal Fishers*

Exposures to Tribal fishers were evaluated assuming direct contact with contaminants in sediment and via consumption of fish. Exposures associated with beach sediment were assessed at individual beaches, and in-river sediment exposures were evaluated on a one-half river mile basis per side of the river and as an averaged, Site-wide evaluation. Fish consumption was evaluated assuming a multi-species diet consisting of anadromous and resident fish species, and fishing was evaluated on a Site-wide basis.

The estimated RME cancer risks associated with direct contact to beach sediment ranged from  $2 \times 10^{-6}$  to  $2 \times 10^{-5}$  at all beaches evaluated. The RME cancer risk estimates for exposure to in-river sediment ranged from  $1 \times 10^{-6}$  to  $3 \times 10^{-4}$  with a Site-wide RME estimate of  $3 \times 10^{-5}$ . RME cancer risk associated with exposure to in-river sediment was greater than  $1 \times 10^{-4}$  at RM 6W and 7W due to cPAHs, arsenic, and dioxin/furans. The CTE cancer risks for beach and in-river sediment ranged from  $6 \times 10^{-8}$  to  $2 \times 10^{-6}$ .

The estimated RME HI risks ranged from 0.003 to 3 at all beach and in-river sediment exposure locations. The RME HI of 3 was due to in-river sediment exposure at RM 7W due to PCBs. The Site-wide RME HI was 0.4. The CTE HIs ranged from 0.0004 to 0.01.

For indirect exposure to infants via breastfeeding assuming maternal exposure to in-river sediment, the RME HIs ranged from 0.01 to 4 at RM 8.5W. The estimated RME HI is greater than 1 at RM 7W, 8.5, and 11E, with risk due entirely to PCBs. The CTE HIs ranged from 0.0006 to 0.1.

For Tribal consumption of fish fillets, the Site-wide RME cancer risk was  $1 \times 10^{-2}$  and for consumption of whole body fish was  $2 \times 10^{-2}$ , primarily due to PCBs. The CTE cancer risk estimate was not calculated.

For Tribal consumption of fish fillets, the Site-wide RME HI risk was 600 and for consumption of whole body fish was 800, primarily due to PCBs.

The RME HI associated with childhood consumption of whole body fish was 800 and was 600 assuming consumption of fillets only, with risk due almost entirely to PCBs. The CTE HIs were not calculated.

The RME HI associated with indirect exposure of Tribal infants via breastfeeding, assuming maternal consumption of whole body fish, was 9,000 and 8,000 assuming maternal fillet-only consumption, with risk due almost entirely to PCBs. The CTE HIs were not calculated.

A summary of risk results for Tribal fishers is shown on Table 11b in Appendix II.

#### *Domestic Water Use*

Use of surface water as a source of household water for drinking and other domestic uses was evaluated using data from five transect and 15 single point sampling locations as well as averaged over a Site-wide basis. The RME estimated cancer risk for combined child and adult exposures ranged from  $9 \times 10^{-6}$  to  $9 \times 10^{-4}$  at RM 6W. The CTE estimated cancer risks ranged from  $3 \times 10^{-6}$  to  $2 \times 10^{-5}$  with a Site-wide CTE estimate of  $3 \times 10^{-5}$ .

The estimated RME HIs based on childhood exposure ranged from 0.1 to 2. Results were equal to or greater than 1 at several sampling locations: W005 (1) at RM 4, W023 (1) at RM 11, W027 (2) near the mouth of Multnomah Channel, and W035 (2) in Swan Island Lagoon. In all instances, 2-(4-chloro-2-methylphenoxy) propanoic acid (MCPP) was the primary contributor to the estimated hazard. The estimated CTE HIs ranged from 0.05 to 0.8 with a Site-wide CTE estimate of 0.6.

#### *Summary*

Risks resulting from the consumption of fish or shellfish were generally orders of magnitude higher than risk resulting from direct contact with sediment, surface water, or seeps. For fish and shellfish consumption, the exposure scenario showing the greatest risk was to subsistence fishers and their breastfeeding infants. For direct contact with in-river sediment, the exposure scenario showing the greatest risk was to Tribal netfishers and their breastfeeding infants. PCBs were the primary contributor to risk from fish consumption harbor wide. When evaluated on a river mile scale, dioxins/furans were a secondary contributor to the overall risk and hazard estimates. PCBs were the primary contributors to the noncancer hazard to nursing infants, primarily because of the bioaccumulative properties of PCBs and the susceptibility of infants to the developmental effects associated with exposure to PCBs.

#### **8.1.5. Uncertainty Analysis for the BHHRA**

Uncertainty is inherent in the risk assessment process. The term “uncertainty” is often used in risk assessment to describe what are, in reality, two conceptually different terms: uncertainty and variability. Uncertainty can be described as the lack of a precise knowledge resulting in a fundamental data gap. Variability describes the natural heterogeneity of a population. Uncertainty can sometimes be reduced or eliminated through further measurements or study. By contrast, variability is inherent in what is being observed. Although variability can be better understood, it cannot be reduced through further measurement or study although it may be more precisely defined.

The risks and hazards presented are consistent with EPA’s stated goal of the RME representing the high end of the possible risk distribution, which is generally considered to be greater than the

90th percentile. However, these estimates are based on numerous and often conservative assumptions and, in the absence of definitive information, assumptions are used to ensure that actual Site risks are not underestimated. The cumulative effect of these assumptions can result in an analysis with an overall conservativeness greater than the individual components. Accordingly, it is important to note that the risks summarized here are based on numerous conservative assumptions in order to be protective of human health and to ensure that the risks are more likely to be overestimated than underestimated.

#### 8.1.5.1. Exposure Parameters for Fish and Shellfish Consumption Scenarios

Site-specific information regarding fish consumption is not available for Portland Harbor prior to its listing as a Superfund site. In the absence of Site-specific data, fish consumption data from several sources were considered and selected as being representative of the general population of the greater Portland area as well as that portion of the population that actively fishes the lower Willamette and utilizes fish from the river as a partial source of food.

The rates presented in the Continuing Survey of Food Intakes by Individuals described in Section 8.1.2.4 represent per capita consumption rates rather than true long-term averaged consumption rates. In addition, the large range between the percentile values is indicative of substantial variability in the underlying data. In addition to the consumption rates, uncertainty also exists with respect to the relative percentage of the diet obtained from the Site or within individual exposure areas versus other nearby sources of fish and the degree to which different methods of preparation and cooking may reduce concentrations of persistent lipophilic contaminants.

#### 8.1.5.2. Using the Maximum Concentration to Represent Exposure

In cases when there were fewer than five samples with a detected concentration for a given analyte for a given exposure area, the sample size was not sufficient to calculate a representative 95% UCL on the mean, so the maximum concentration detected was used as the exposure point concentration. Data sets with fewer than 10 samples generally provide poor estimates of the mean concentration, defined as a large difference between the sample mean and the 95% UCL. In general, the UCL approaches the true mean as more samples are included in the calculation of the exposure concentration.

Exposure point concentrations on a river mile scale used data from smallmouth bass to represent contaminant concentrations in all resident fish species, and consumption was assumed to consist primarily of just the fillet rather than other parts of the fish. However, an evaluation of the data collected from Portland Harbor indicated that PCB concentrations in whole body smallmouth bass were typically an order of magnitude greater than those measured in just the fillet. By contrast, in common carp and brown bullhead, the observed ratio of whole body-to-fillet PCB concentrations is less than noted in smallmouth bass, meaning that given the same overall PCB concentration in whole body fish, the PCB concentration in smallmouth bass fillet tissue would be less than for carp and bullhead. These differences are reflected in the exposure concentrations such that the use of fillet smallmouth bass data on a river mile scale resulted in a greater relative reduction of PCB concentration than would be seen if fillet data from common carp and brown bullhead were included. A diet that consists of some portion of carp and bullhead could result in

relatively greater intake of PCBs, and the associated risk and hazard would be correspondingly greater. In addition, at least some of the fishers in the Portland Harbor area consume more than just the fillet. Consumption of other portions of the fish in addition to the fillet can result in greater relative exposure to PCBs and other persistent bioaccumulative chemicals and, thus, greater relative risks.

#### 8.1.5.3. Regional Tissue Concentrations

PCBs and dioxins/furans have been detected in fish tissue collected in the Willamette and Columbia rivers, outside of the Site. In the Columbia River Basin Fish Contaminant Survey, the basin-wide average concentrations of total PCBs in resident fish ranged from 0.032 to 0.173 parts per million (ppm) for whole body samples and from 0.033 to 0.190 ppm for fillet with skin samples. In the middle Willamette River (RM 26.5 to 72), the average concentrations of total PCBs in resident fish ranged from 0.086 to 0.146 ppm for whole body samples and from 0.026 to 0.071 ppm for fillet with skin samples. The regional tissue concentrations may be associated with unacceptable risks from fish consumption, especially at higher consumption rates. However, these regional concentrations are lower than the concentrations detected in the Site where average concentrations ranged from 0.16 to 2.8 ppm in whole body samples and from 0.17 to 2.5 ppm in fillet with skin samples (for PCBs as total congeners). The fish species included in the studies were different than those collected within the Site, so the concentrations may not be directly comparable. Sources contributing to the PCBs and dioxins/furans detected in fish collected outside of the Site are unknown and may not be relevant to the Site.

## 8.2. Ecological Risks

This section summarizes the BERA for aquatic and aquatic-dependent species exposed to hazardous substances associated with the in-river Willamette River portion of the Site. The BERA defined the Willamette River as all areas lower in water surface elevation than the ordinary high water mark, including nearshore riparian zone areas not normally inundated by water.

The specific overall objectives of the BERA were:

- Identify the risks posed by chemical contaminants to aquatic and aquatic-dependent ecological receptors associated with the Site under baseline conditions.
- In the event that unacceptable ecological risks require remedial actions at the Site, provide information that risk managers can use to make remedial action decisions that are protective of ecological receptors.

The numerous aquatic and aquatic-dependent organisms that use the lower Willamette River can be divided into the following general groups: invertebrates, fishes, birds, mammals, amphibians, reptiles, and aquatic plants. All organisms present within the Site contribute to the ecological functioning of the river. Riverine invertebrates are predominantly benthic (i.e., living in or associated with river bottom substrates such as fine-grained sediment, gravel and cobble, plant roots, and large woody debris). The benthic invertebrate community within the lower Willamette

River is dominated by small benthic organisms, many of which feed on organic material imported from upstream areas.

The Willamette River is an important migration corridor for anadromous fishes, including Pacific lamprey and multiple salmon species, and provides habitat for approximately 50 resident fish species. Fish present in the river can be grouped into four major feeding guilds: omnivores/herbivores, invertivores, piscivores, and detritivores. Over 20 commonly occurring aquatic-dependent bird species use habitats and feed on aquatic species within the Site. The trophic representation of these birds is broad and includes herbivores, carnivores, and omnivores; sediment-probing invertivores and omnivores; and piscivores. Seven aquatic or semi-aquatic mammals use or may use the river within the Site, including herbivores, omnivores, and piscivores.

Procedures used in the BERA to evaluate the nature, severity, and areal extent of risks to ecological receptors in Portland Harbor were based on an iterative approach, beginning with a screening-level ecological risk assessment, followed by a more detailed and rigorous BERA. The BERA steps are listed below and described in the following sections:

- **Problem Formulation** includes identification of COPCs, exposure pathways, and known ecological effects of the contaminants; receptors and selection of assessment endpoints (environmental values to be protected) for further study and a CSM.
- **Exposure Assessment** includes characterization of exposure pathways and receptors; and measurement or estimation of exposure point concentrations.
- **Ecological Effects Assessment** includes literature reviews, field studies, and toxicity tests, linking contaminant concentrations to adverse effects on ecological receptors on a media-, receptor-, and chemical-specific basis.
- **Risk Characterization** includes measurement or estimation of both current and future adverse effects as well as the overall degree of confidence in the risk estimates.

### **8.2.1. Problem Formulation**

The BERA problem formulation consisted of the tasks described below.

#### *Identification of COPCs*

The final BERA number of COPCs is presented in Table 12 in Appendix II, including the number of contaminants in each medium with no screening-level or refined screen toxicity reference values (TRVs). Risks associated with these contaminants were evaluated if alternative methods were available to derive TRVs; otherwise, risks from these contaminants could not be quantified.

The groups of contaminants identified as BERA COPCs are summarized in Table 13 in Appendix II. Screening resulted in a combined 104 COPCs for benthic invertebrates across four media (sediment, invertebrate tissue, surface water, and TZW). A combined 74 fish COPCs were identified, based on summing the COPCs across all media and the dietary line of evidence

(LOE). Twenty-three COPCs were identified for birds through two LOEs, and 12 COPCs were identified for mammals based on one LOE. Finally, 64 COPCs were identified for amphibians and aquatic plants through two LOEs.

### *Exposure Pathways*

The BERA CSM is presented in Figure 5 in Appendix I. The routes of exposure are the means by which contaminants are transferred from a contaminated medium to an ecological receptor. The most significant pathways for Portland Harbor COPCs are:

- Aquatic plants: Root uptake; direct contact with sediment, surface water, and TZW
- Benthic invertebrates: Direct contact with sediment, surface water, and TZW; ingestion of sediment and food
- Fish: Direct contact with sediment, surface water, and TZW; ingestion of sediment and food
- Birds and mammals: Ingestion of soil, sediment, and food
- Amphibians: Direct contact with surface water and TZW; ingestion of sediment and food

### *Ecological Effects Characterization*

Ecological effects characterization resulted in the final list of TRVs and sediment quality values (SQVs) for the various environmental media and samples evaluated. TRVs and SQVs are contaminant concentrations in media, which, if not exceeded, describe contaminant concentrations considered to pose no or acceptable levels of ecological risk.

### *Receptors*

The primary selection criteria for ecological receptors were that: (1) they represent the feeding guilds (a group of species that share similar feeding strategies or diets) present at Portland Harbor; (2) the receptors use the same habitat as other similar species; (3) the receptors are susceptible to contaminants; and (4) they are ecologically, culturally, and/or economically significant. Using these criteria, 13 ecological receptors (see below) were selected for evaluation.

### *Assessment Endpoint Selection*

The BERA included development of the assessment endpoints, risk questions, measurement endpoints, and LOEs. For each assessment endpoint, risk questions and testable hypotheses were developed. The BERA evaluated 13 assessment endpoints; 12 of the 13 assessment endpoints took the form of “survival, growth, and reproduction of” a group of species that share a habitat, taxonomic category, or feeding guild. The 12 assessment endpoints with the form “survival, growth, and reproduction of” were:

- Aquatic plants (aquatic plant community including phytoplankton, periphyton, macrophyte species)

- Benthic macroinvertebrates<sup>6</sup> (benthic macroinvertebrate community)
- Bivalves (clams)
- Decapods (crayfish)
- Invertivorous fish (sculpin, peamouth, and juvenile Chinook salmon)<sup>7</sup>
- Omnivorous fish (largescale sucker, carp, and pre-brccding white sturgeon)
- Piscivorous fish (smallmouth bass and northern pikeminnow)
- Detritivorous fish (Pacific lambrey ammocoetes)
- Amphibians (frog and salamander species)
- Piscivorous birds (osprey, bald eagle)
- Omnivorous birds<sup>8</sup> (hooded merganser)
- Invertivorous birds (spotted sandpiper)
- Aquatic-dependent mammals (mink and river otter)

For the 13<sup>th</sup> assessment endpoint, detritivorous fish (Pacific lamprey ammocoetes), reproduction was not evaluated because the reproducing life stage of the lamprey was not present.

### **8.2.2. Ecological Exposure Assessment**

#### *Exposure Pathways and Receptors*

Exposure data were evaluated at the scale over which the receptors are likely to be exposed and, where pertinent, the variety of potentially contaminated prey the receptor may consume. For the least mobile receptors (benthic macroinvertebrates, sculpin, aquatic plants), exposure areas are no larger than the immediate area where samples were collected. For the most mobile receptors (white sturgeon, largescale sucker), the exposure areas encompass the entire Site. For moderately mobile receptors (e.g., smallmouth bass, mink) the Site is divided into several exposure areas, each 1 to 3 miles long.

#### *Exposure Concentrations*

For dietary risks to fish and wildlife, exposure estimates were determined for a diet consisting of multiple prey species. Exposure concentrations were based both on measured contaminant

---

<sup>6</sup> Clams and crayfish are members of the benthic macroinvertebrate community, but were evaluated separately to provide a population level assessment.

<sup>7</sup> Juvenile Chinook salmon were evaluated at the organism level; all other invertivorous fish receptor species selected were evaluated at the population level.

<sup>8</sup> Belted kingfisher was evaluated in the uncertainty assessment, as previously agreed to by EPA and the LWG. The belted kingfisher ingests a considerable amount of fish, is present year-round, and consumes a variety of prey. Belted kingfisher was included in the uncertainty evaluation to confirm that the evaluations performed on bald eagle, osprey, and merganser are protective of the belted kingfisher.

concentrations and, for some LOEs (the tissue-residue LOE and the dietary LOE for shorebirds), on predicted values.

### **8.2.3. Ecological Effects Assessment**

#### *Effects of Contaminant Concentrations*

The effects assessment involved two general approaches. For most receptors, the COPCs effects were assessed by comparing contaminant concentrations in each medium with contaminant- and medium-specific TRVs or Site-specific SQVs. The lowest-observed-adverse-effect level TRVs were used for all receptors evaluated at the community or population level. No-observed-adverse-effect level TRVs were used for species listed as threatened under the ESA such as the juvenile Chinook salmon and Pacific lamprey ammocetes.

#### *Sediment Toxicity Tests*

The second effects assessment approach used sediment toxicity bioassays as a direct measure of the effects of sediment contaminant mixtures on the survival and biomass of benthic invertebrates in the laboratory. Two predictive models (the floating percentile model and logistic regression model) were used to develop Site-specific SQVs. The goals of both models were to predict benthic toxicity for locations with no measured toxicity data and to define Site-specific SQVs based on associations between measured sediment chemistry and measured sediment toxicity.

### **8.2.4. BERA Risk Characterization**

During risk characterization, information from the exposure assessment and ecological effects assessment are combined into descriptions of the likelihood of unacceptable ecological risk. The risk characterization included information on the contaminants posing potentially unacceptable risk, which receptors were at risk, the media and exposure pathways in which contaminants posing potentially unacceptable risks were found, the magnitude of the risks, and the location(s) of risks within the Site.

In addition to the quantitative calculations performed to estimate risks, the risk characterization also discusses the level of agreement among the multiple LOEs used to assess risks to the assessment endpoints, the relative strengths and weaknesses of each LOE, the ecological significance of identified risks, and the uncertainties associated with the risk assessment conclusions.

#### *Benthic Invertebrate Toxicity Tests*

Sediment toxicity tests evaluated adverse effects of Portland Harbor sediment on survival and biomass (a combined survival and growth endpoint) of larvae of the aquatic insect *Chironomus dilutus* and juveniles of the amphipod *Hyaella azteca*. The toxicity tests demonstrated that exposure of these animals to sediment from some Portland Harbor locations resulted in increased mortality and/or reduced biomass of these two species within 10 to 28 days — a direct measure of sediment toxicity to benthic invertebrates. A weight-of-evidence analysis identified 17 benthic areas of concern within the Site. Most samples and locations eliciting multiple instances of

moderate and severe toxicity tended to cluster in several areas, especially between RM 5.9 and 7.8 on the west side of the river. Other areas with “clusters” of benthic toxicity included:

- International Slip
- Between RM 3.7 and 4.2, west side of river
- Between RM 4.8 and 5.2, west side of river
- Willamette Cove
- Near the mouth of Swan Island Lagoon
- RM 8.7 to 8.8, west side of river

Combined, the above areas cover between 4 and 8% of the total surface area of sediment within the Site. Contaminants at elevated concentrations relative to SQVs in these areas are the most likely to pose risks to benthic invertebrates. SQVs are included in BERA Tables 6-8 and 6-10 through 6-15.

#### *Other Lines of Evidence*

Most risk characterizations were made using the HQ method. An HQ is calculated by dividing the exposure point concentration by the selected TRV. COPCs with an  $HQ \geq 1.0$  were identified as contaminants posing potentially unacceptable risk. The potential for unacceptable risk becomes increasingly large as the HQ value increases although the increase is not necessarily linear.

Table 14 in Appendix II tallies the COPCs (individual chemicals, sums, or totals) identified as posing potentially unacceptable risk for each assessment endpoint. In total, 93 CERCLA contaminants were identified as posing potentially unacceptable risk in the BERA based on  $HQ \geq 1.0$  for at least one receptor-LOE combination. Of these, 22 COPCs are only applicable to benthic invertebrates as predicted by the floating percentile model or logistic regression model. These models predicted the suite of contaminants, which combined correlate with observed patterns of toxicity to benthic organisms, rather than identifying specific contaminants that cause toxicity.

The maximum HQ and number of samples resulting in  $HQ \geq 1.0$  for each receptor-LOE COPC combination posing potentially unacceptable risk are as follows:

- Benthic invertebrates: Eighty-seven COPCs were identified via one or more of the sediment, tissue-residue, surface water, and TZW LOEs.
- Fish: Sixty-two COPCs were identified using the tissue-residue, dietary-dose, surface water, and TZW LOEs.
- Wildlife: Eleven COPCs were identified for birds using the dietary-dose and tissue-residue (egg) LOEs, and six COPCs were identified for mammals using the dietary-dose LOE.

- Amphibians: Thirty-five COPCs were identified using the surface water and TZW LOEs.
- Aquatic plants – Thirty-five COPCs were identified using the surface water and TZW LOEs.

Table 15 in Appendix II provides a summary of the contaminants posing potentially unacceptable risks by river mile in selected media (sediment, surface water, TZW, field clam and mussel tissue, smallmouth bass tissue, and sculpin tissue).

### **8.2.5. Ecologically Significant Contaminants of Concern**

Ecological significance can be defined as the importance of an adverse effect on population, community, or ecosystem responses. Factors contributing to ecological significance considered in the BERA included the nature and magnitude of effects, the spatial and temporal extent of effects, uncertainties in the exposure assessment, uncertainties in the effects characterization, and concordance of the various LOEs used to assess risk to communities or populations.

Contaminants of ecological significance were identified based on the following criteria:

1. Had relatively high HQs in one or more environmental media
2. Had potentially unacceptable ecological risks over extensive areas
3. Spatial extent of potentially unacceptable risk encompassed many other contaminants that posed a risk at only one or a few locations in the Site
4. Had potentially unacceptable risks to multiple ecological receptors
5. Multiple LOEs indicated potentially unacceptable risks
6. Known or has potential to biomagnify in food webs

Of the contaminants of ecological significance posing unacceptable risks, 4 primary contaminants (PCBs, PAHs, dioxins/furans, and DDX) and 16 other contaminants (BEHP, cadmium, chlordanes, copper, cyanide, dieldrin, ethylbenzene, lead, Lindane [ $\gamma$ -hexachlorocyclohexane], manganese, mercury, perchlorate, tributyltin, total petroleum hydrocarbons-diesel, vanadium, and zinc) were determined to pose risks ecologically high enough to be considered in the development of remedial actions. Table 16 in Appendix II lists contaminants posing unacceptable risk to receptor groups.

Contaminants posing potentially unacceptable risk at the end of the BERA that are not listed above will be compared with post-remedial action conditions to confirm that alternatives developed for the ecologically significant contaminants would also be protective of risks of lower ecological significance.

### **8.2.6. Risk Characterization Summary**

The primary conclusions of the BERA are:

- In total, 93 CERCLA contaminants posed ecological risk; 64 were categorized as contaminants of ecological significance that pose unacceptable risk. Of the 64, 4 primary

and 16 other contaminants posed risk significant enough to be considered in the development of remedial alternatives.

- Risks to benthic invertebrates were clustered in 17 benthic areas of concern.
- Sediment and TZW samples with the highest HQs for many contaminants also tended to be clustered in areas with the greatest benthic invertebrate toxicity.
- PAH and DDX compounds were the contaminants in sediment most commonly spatially associated with locations of unacceptable risk to the benthic community or populations.
- PCBs were associated with ecological risks to mammals and birds.
- The combined toxicity of dioxins/furans and dioxin-like PCBs posed the potential risk of reduced reproductive success in mink, river otter, spotted sandpiper, bald eagle, and osprey. The PCB toxic equivalent concentration (TEQ) fraction of the total TEQ was responsible for the majority of total TEQ exposure, but the total dioxin/furan TEQ fraction also exceeded its TRV in some locations of the Site.
- The area of sediments posing ecological risk was approximately 1,290 acres, or 69% of the Site based on the contaminants of ecological significance and benthic risk.

#### **8.2.7. BERA Assessment Uncertainties**

Uncertainty has four components: variation, model uncertainty, decision rule uncertainty, and true unknowns. Examples of these types of uncertainty are:

- Variation: A fish is exposed to a range of contaminant concentrations in water, not to a constant concentration of a contaminant.
- Model uncertainty: Use of a single species or several target ecological receptors within a feeding guild to represent all species within that guild introduces uncertainty because of the considerable amount of interspecies variability in sensitivity to a contaminant.
- Decision rule uncertainty: Use of standard EPA default values, such as assuming contaminants are 100% bioavailable, because defaults are used as single-point values throughout the BERA, despite having both variation and model uncertainty associated with them.
- True unknowns: For example, the effects of titanium in water on smallmouth bass survival, growth, and reproduction has never been studied and is unknown.

Consistent with the problem formulation methods, receptor-COPC pairs posing potentially unacceptable risk were identified using conservative methods and assumptions. Examples of conservatism include assumptions that contaminant concentrations are 100% bioavailable and assumptions that resulted in low baseline TRVs, which in the case of nutritionally essential metals such as copper, had to be adjusted upward because they were below nutritional requirements for some, but not all, fish species.

Not all uncertainties create a conservative bias. Some can lead to an underestimation of risk such as unavailability of exposure or effects data, thresholds that do not account for untested sensitive species, uncertainty whether multiple Site COPCs interact synergistically, and uncertainty whether metabolic processes increase the toxicity of accumulated contaminants in ways that are not observed in toxicity tests.

Unquantified ecological risks from contaminants without baseline TRVs are a source of uncertainty in the BERA that could lead to underestimating ecological risks within Portland Harbor because most other types of uncertainty are handled by making conservative assumptions.

### 8.3. Basis for Action

The response action selected in this ROD is necessary to protect public health or welfare or the environment from actual or threatened releases of hazardous substances to the environment and pollutants or contaminants which may present an imminent and substantial endangerment to the public health or welfare. A response action is necessary for the Site because:

- **Human health risk:** Risks resulting from exposure to beach and in-river sediment and the consumption of fish and/or shellfish exceed EPA's cancer risk range and HI assessment, as summarized in Section 8.1.4.1.
  - **Sediment:** Exposure to beach and/or in-river sediment results in elevated risks to several of the receptors evaluated.
  - **Biota:** Site-wide, consumption of fish and invertebrates by subsistence, recreational, and Tribal fishers significantly exceeded EPA's cancer risk range and HI target values.
  - **Surface Water:** Direct and indirect risks due to surface water contamination and the bioconcentration potential of numerous Site COCs impact Site receptors.
  - **Groundwater:** Direct and indirect risks due to contaminated groundwater entering the river result in exposure of Site receptors.
  - **River banks:** Contaminated river banks are likely to act as uncontrolled sources to the in-river portion of the Site.
- **Ecological risk:** Risks to ecological receptors exceed acceptable levels ( $HQs \geq 1.0$ ) in many areas of the Site, especially to benthic invertebrates and other sediment-associated receptors.
  - **Sediment:** Sediment and TZW samples with the highest HQs for many contaminants also tend to be clustered in areas with the greatest benthic invertebrate toxicity. PAH and DDx compounds are the contaminants in sediment that are most commonly spatially associated with locations of unacceptable risk to the benthic community or populations.

- **Biota:** PCBs are associated with ecological risks to mammals and birds. The combined toxicity of dioxins/furans and dioxin-like PCBs poses the potential risk of reduced reproductive success in mink, river otter, spotted sandpiper, bald eagle, and osprey. The PCB TEQ fraction of the total TEQ is responsible for the majority of total TEQ exposure, but the total dioxin/furan TEQ fraction also exceeds its TRV in some locations of the Site.
- **Surface water:** Direct exposure of in-river ecological receptors results in unacceptable risk. Natural recovery of surface water is unlikely within a reasonable timeframe.
- **Groundwater:** Risks associated with TZW and/or pore water represent the inflow of contaminated groundwater from upland sources entering the ecologically sensitive zone. Natural recovery of groundwater is unlikely within a reasonable timeframe.
- **River banks:** Contaminated river banks are likely to act as uncontrolled sources to the in-river portion of the Site. Natural recovery of river banks is unlikely within a reasonable timeframe.

## 9. REMEDIAL ACTION OBJECTIVES

RAOs consist of media-specific goals for protecting human health and the environment. RAOs have been developed for COCs in the environmental media of interest; exposure pathways, including exposure routes and receptors; and an acceptable contaminant concentration or range of concentrations for each exposure route. The nine RAOs developed to address the human health and ecological risks posed by the contamination at the Site are presented below.

### *Human Health RAOs*

- **RAO 1 – Sediment: Reduce cancer and non-cancer risks to people from incidental ingestion of and dermal contact with COCs in sediment and beaches to exposure levels that are acceptable for fishing, occupational, recreational, and ceremonial uses.** Reducing concentrations, exposure to, and the bioavailability of the COCs in nearshore sediment and beaches will reduce risk at the Site. Ongoing source control efforts and the use of institutional controls (such as signs and fences) will provide additional risk reduction.
- **RAO 2 – Biota: Reduce cancer and non-cancer risks to acceptable exposure levels (direct and indirect) for human consumption of COCs in fish and shellfish.** Reducing concentrations, exposure to, and the bioavailability of the COCs in sediment will subsequently reduce surface water and fish and shellfish tissue concentrations and will reduce risk at the Site. Ongoing source control efforts and the use of fish consumption advisories and education and outreach programs will provide additional risk reduction.
- **RAO 3 – Surface Water: Reduce cancer and non-cancer risks to people from direct contact (ingestion, inhalation, and dermal contact) with COCs in surface water to exposure levels that are acceptable for fishing, occupational, recreational, and**

**potential drinking water supply.** Reducing concentrations, exposure to, and the bioavailability of COCs in sediment will subsequently reduce surface water concentrations and will reduce risk at the Site. Ongoing source control efforts will provide additional risk reduction.

- **RAO 4 – Groundwater: Reduce migration of COCs in groundwater to sediment and surface water such that levels are acceptable in sediment and surface water for human exposure.** Reducing concentrations, exposure to, and the bioavailability of COCs in the pore water and groundwater flux to surface water and sediment will reduce risk at the Site. Ongoing source control efforts will provide additional risk reduction.

#### *Ecological RAOs*

- **RAO 5 – Sediment: Reduce risk to benthic organisms from ingestion of and direct contact with COCs in sediment to acceptable exposure levels.** Reducing concentrations, exposure to, and the bioavailability of the COCs in sediment will reduce risk at the Site. Ongoing source control efforts will provide additional risk reduction.
- **RAO 6 – Biota (Predators): Reduce risks to ecological receptors that consume COCs in prey to acceptable exposure levels.** Reducing concentrations, exposure to, and the bioavailability of the COCs in sediment will subsequently reduce surface water concentrations and in fish and shellfish and will reduce risk at the Site. Ongoing source control efforts will provide additional risk reduction.
- **RAO 7 – Surface Water: Reduce risks to ecological receptors from ingestion of and direct contact with COCs in surface water to acceptable exposure levels.** Reducing concentrations, exposure to, and the bioavailability of COCs in sediment will subsequently reduce surface water concentrations and will reduce risk at the Site. Ongoing source control efforts will provide additional risk reduction.
- **RAO 8 – Groundwater: Reduce migration of COCs in groundwater to sediment and surface water such that levels are acceptable in sediment and surface water for ecological exposure.** Reducing concentrations, exposure to, and the bioavailability of COCs in the pore water and in groundwater entering surface water will reduce risk at the Site. Ongoing source control efforts will provide additional risk reduction.

#### *Human Health and Ecological*

- **RAO 9 – River Banks: Reduce migration of COCs in river banks to sediment and surface water such that levels are acceptable in sediment and surface water for human health and ecological exposures.** Reducing concentrations, exposure to, and the bioavailability of the COCs in river banks will reduce risk and recontamination at the Site. Ongoing source control efforts will provide additional risk and recontamination reduction.

RAOs simultaneously address both current and future land and waterway uses since future land and waterway uses are not anticipated to change significantly from the current usage. Section 7

includes descriptions of land and river uses. Achieving the above RAOs relies on the remedial alternatives' ability to meet cleanup levels. Cleanup level development is discussed in Section 9.1, including risk-based cleanup levels, applicable or relevant and appropriate requirements (ARARs)-based cleanup levels, and cleanup levels based on background concentrations.

It is EPA's expectations that DEQ's actions to address upland source control will adequately address contaminated soils, surface water, and especially groundwater contamination migrating to the river consistent with CERCLA. Response actions will address contamination within the in-river portion of the Site and associated river banks. There are known sources of contamination in the upland areas and known sources in locations in the downtown reach of the river (approximately RM 12 to RM 16.6). EPA is relying on the Oregon DEQ to use its authorities to address these sources. It is expected that controlling these sources will reduce or eliminate contamination in soil, groundwater, storm water, and surface water that migrates to the Willamette River. Since the achievement of cleanup levels identified in the Selected Remedy relies in part upon timely and successful completion of these upland and upstream source area actions, EPA retains the discretion to use its federal authorities to complete those actions. The RAOs above relate to the action described in this ROD conducted under CERCLA, and meeting the above objectives is dependent on the source control actions being conducted by DEQ. In addition, an objective for addressing groundwater contamination, beyond its impact on sediment and surface water, is not included in this action as groundwater contamination is primarily due to the upland sources being addressed by the DEQ source control actions.

The remedial strategy for the Site is to address all contaminated media and complete exposure pathways that pose unacceptable risk within the river, including sediment, biota, surface water, groundwater, and river banks. The remedial strategy will primarily rely on addressing the contaminated sediments in Portland Harbor to significantly reduce potential human health and ecological risks at the Site and achieve all of the RAOs. Remediation of the sediment will reduce loading and resuspension of contamination to surface water which collectively will reduce fish and shellfish exposure to the contamination. Likewise, addressing areas with contaminated groundwater discharging to the river by dredging and capping will also reduce loading to surface water and reduce exposure to benthic and invertebrate organisms living in sediment. Remediation of the sediment within the Site will have a substantial positive impact downstream, including the Columbia River. Although reducing loading to the Columbia River is not a direct objective of this action, it is an expected ancillary result of achieving the RAOs presented above.

### **9.1. Cleanup Levels**

Cleanup levels are the long-term contaminant concentrations that need to be achieved by the remedial alternatives to meet RAOs. They must comply with ARARs (or the basis for a waiver must be provided) and result in residual risk levels that fully satisfy the CERCLA requirements for the protection of human health and the environment. COCs for the Site are identified in Table 17 in Appendix II. Site-specific cleanup levels were developed for each RAO for the following media: sediment (including beaches), river bank soil, surface water, and groundwater.

### **9.1.1. Human Health Risk-Based Cleanup Levels**

Human health risk-based cleanup levels were calculated assuming an RME based on direct contact with beach and in-river sediment (RAO 1). Human health risk-based cleanup levels were calculated for sediment to be protective of indirect exposures through consumption of fish and shellfish (RAO 2). Risk-based sediment cleanup levels for cancer effects were calculated based on an excess cancer risk of  $1 \times 10^{-6}$  (1 individual out of 1 million) and risk-based cleanup levels for non-cancer effects were calculated as concentrations that would result in an HQ of 1. Sediment concentrations needed to meet protective fish and shellfish tissue concentrations were estimated using a food-web model calibrated to predict COC concentrations in fish based on the concentration in sediment and surface water. Risk-based sediment cleanup levels protective of fish/shellfish consumption were not developed for arsenic, hexachlorobenzene, mercury, BEHP, pentachlorophenol, and polybrominated diphenyl ether because a relationship between fish and/or shellfish tissue and sediment concentrations could not be determined. Risk associated with these contaminants will be addressed by meeting cleanup levels for the other COCs and through ICs. The risk-based cleanup levels for RAOs 1 and 2 represent the lowest value in each medium (beach or in-river sediment) to be protective of all potential receptors. Cleanup levels that are based on risk are indicated in Table 17 in Appendix II.

#### **9.1.1.1. Human Health-Based Fish Tissue Targets**

Human health risk-based targets were calculated for fish/shellfish tissue based on the food-web model described above. These levels of chemicals in fish/shellfish tissue are not cleanup levels but will be monitored throughout the cleanup and will, at a minimum, be used to inform fish advisories. PCB targets are risk based and are likely lower than background tissue levels. These targets are included in Table 17 in Appendix II.

### **9.1.2. Ecological Risk-Based Cleanup Levels**

Ecological risk-based cleanup levels were developed for sediment, surface water, and groundwater/pore water to meet the objectives associated with RAOs 5 through 8. Risk-based cleanup levels were developed from medium- and contaminant-specific TRVs protective of ecological receptors evaluated in the BERA. Risk-based cleanup levels in sediment were selected from protective TRVs presented in the BERA and address ingestion and direct contact of benthic organisms with sediment (RAO 5). Cleanup levels based on consumption of prey (RAO 6) were calculated using the food-web model to predict acceptable COC concentrations in prey based on sediment and surface water concentrations. The lowest value for each COC was selected as the risk-based cleanup level for RAOs 5 and 6 to be protective of all species. COC-specific water concentrations from the BERA that are protective of ecological receptors were selected as risk-based cleanup levels for RAOs 7 and 8, with the exception of the manganese cleanup level for RAO 8. The RAO 8 cleanup level for manganese was developed subsequent to the BERA, and the methodology is described in Windward 2014. Cleanup levels that are based on risk are indicated in Table 17 in Appendix II.

### **9.1.3. Cleanup Levels Based on Applicable or Relevant and Appropriate Requirements**

CERCLA requires remedial actions to comply with all applicable or relevant and appropriate federal environmental or promulgated state environmental or facility siting laws, unless such standards are waived. CERCLA stipulates that a remedy that does not attain an ARAR can be selected if the remedy assures protection of human health and the environment and meets one of six waiver criteria described in CERCLA. EPA has no information to justify waiving any of the identified ARARs at this Site.

The substantive portions of the following key ARARs and To Be Considered (TBCs) were used in developing cleanup levels:

#### *ARARs*

- Federal National Recommended Water Quality Criteria (NRWQC)
- Oregon numeric water quality standards (WQS)
- Maximum contaminant levels (MCLs) and non-zero maximum contaminant level goals (MCLGs) established under authority of the Safe Drinking Water Act (SDWA) since the river is a drinking water source
- Oregon Hazardous Substance Remedial Action (OHSRA) rules that set standards for the degree of cleanup required and establish acceptable residual risk levels for humans at  $1 \times 10^{-6}$  for individual carcinogens,  $1 \times 10^{-5}$  for multiple carcinogens, and an HI of 1 for noncarcinogens.

#### *TBCs*

- EPA regional screening levels (RSLs) for tap water (EPA 2014) established at a  $10^{-6}$  risk level.

The cleanup levels for RAOs 3 and 4 are based on the lower of the Federal NRWQC (organism + water) and Oregon WQSs (organism + water), MCLs, and non-zero MCLGs. EPA RSL values were only selected as cleanup levels when a value was not available based on NRWQCs, Oregon WQSs, or MCLs for a specific contaminant. Two RSL-based numbers were identified: manganese and MCP. The cleanup levels for RAO 7 are based on the lower of the NRWQC (chronic aquatic life) and Oregon WQS (chronic aquatic life) only when risk-based values are not available or are greater than ARARs. ARARs-based numbers are used for TBT (RAO 7) and arsenic, chromium, and DDx (RAO 8). Cleanup levels that are based on ARARs are indicated in Table 17 in Appendix II.

### **9.1.4. Background Concentrations**

EPA evaluated sediment contaminant concentrations in locations that were not influenced by releases from the Site and were either naturally occurring or anthropogenic. If background concentrations are higher than the cleanup level, EPA defaults to the background concentration as a matter of policy. Background concentrations in sediment for the Site are provided in Section

2 in the FS (EPA 2016b). Data were insufficient to compute defensible background concentrations for other media. Cleanup levels for sediment and river bank soils that are based on background are indicated in Table 17 in Appendix II.

#### **9.1.5. Summary of Selected Cleanup Levels and Fish Tissue Targets**

The NCP identifies a  $10^{-6}$  cancer risk level or a noncancer HQ of 1 as the goal of protection for determining remediation goals for alternatives when ARARs are not available or are not sufficiently protective. As summarized above, the FS provides the basis for each cleanup level, including Site-specific risk, chemical-specific ARARs, and consideration of sediment background concentrations of COCs entering the Site from upstream. The risk-based cleanup levels were compared to the chemical-specific ARARs, and the lower of the two values was then compared to background. Where both the risk-based cleanup level and chemical-specific ARAR were less than the background concentration, the background concentration was selected as the cleanup level. Cleanup levels for RAO 9 (river bank soil) were selected as the lowest sediment cleanup level for each COC to ensure that sediment would not be re-contaminated. Table 17 in Appendix II presents the cleanup levels or targets for the affected media and whether the selected value is risk based, ARARs based, or background based.

The remedial design will include development of points of compliance for all affected media at the Site, including sediment, surface water, river bank soils, pore water, and groundwater. Points of compliance measurements developed in the design will include both spacial and temporal performance standards. Fish tissue targets will be used to update fish advisories, assess whether the Selected Remedy will achieve RAOs, make adjustments to best management practices (BMPs), and their uses will be further defined in the monitoring plans.

### **10. DEVELOPMENT AND DESCRIPTION OF ALTERNATIVES**

#### **10.1. Summary of Remedial Alternatives**

EPA developed nine remedial alternatives for the Site that addressed the RAOs, considered the requirements of CERCLA and the NCP, and considered the large, complex nature of the Site. Detailed information about the remedial alternatives is provided in the FS Report (EPA 2016b). CERCLA mandates that remedial actions must be protective of human health and the environment, be cost-effective, and use permanent solutions and alternative treatment technologies or resource recovery alternatives to the maximum extent practicable. Section 121(b)(1) also establishes a preference for remedial actions which employ, as a principal element, treatment to permanently and significantly reduce the volume, toxicity, or mobility of the hazardous substances, pollutants, and contaminants at a site. CERCLA § 121(d), 42 U.S.C. § 9621(d), further specifies that a remedial action must require a level or standard of control of the hazardous substances, pollutants, and contaminants, which at least attains ARARs under federal and state laws, unless a waiver can be justified pursuant to CERCLA § 121(d)(4), 42 U.S.C. § 9621(d)(4).

There are limited technologies available for addressing contaminated sediment. The technologies available include ICs, MNR, ENR, containment, sediment/soil treatment (in-situ and ex-situ),

sediment/soil removal, and disposal. Using these technologies, nine remedial alternatives were developed in the FS and labeled A through I. Alternative A is a No-Action alternative, while Alternatives B through I all use a combination of these technologies to varying degrees. In addition, Alternatives E through I were evaluated with two disposed material management (DMM) scenarios described in Section 10.1.1.4.

In developing the different alternatives, sediment management areas (SMAs) were identified as areas where containment or removal technologies were considered to immediately reduce risks upon implementation. The SMAs represent areas with contaminant concentrations in surface sediment where natural recovery is not occurring or is not likely to be effective in reducing concentrations of COCs within a reasonable time frame. Additionally, the presence of PTW and in-situ treatment areas for PTW were used to delineate SMAs (see the PTW description in Section 6.5.1).

The COCs used to define the SMA boundaries encompassed the majority of the spatial extent of contaminants posing the majority of the risks as identified in the baseline risk assessments (see Section 8). However, since it is difficult to design a range of alternatives for 64 COCs that have different distributions in various media throughout the Site, the FS alternatives were developed using COCs that were the most widespread and posed the greatest risk, called focused COCs.

The focused COCs are:

- PCBs
- Total PAHs
- DDX
- Dioxin/furans (1,2,3,7,8-PeCDD; 2,3,4,7,8-PeCDF; and 2,3,7,8-TCDD)

The SMA footprints for each alternative are defined by exceedences of remedial action levels (RALs) and the presence of PTW. RALs are contaminant-specific sediment concentrations of focused COCs used to identify areas where capping and/or dredging will be conducted in order to reduce risks more effectively than ENR or MNR. Each alternative has a different set of sediment RALs, based on Site-wide average concentrations. The highest RALs are in Alternative B and the lowest RALs are in Alternative H. RALs are a tool commonly used at sediment sites to develop remedial alternatives, delineating areas greater than the defined concentration threshold, and to evaluate different alternatives and whether they achieve sediment cleanup levels within a reasonable time frame. The use and application of RALs does not affect or alter the requirement to achieve cleanup levels.

The evaluation and analysis used to develop the RALs is discussed in Appendix D of the FS. The RALs were developed by considering the volume or acreage of material that would be addressed in order to achieve reductions of contaminant concentrations (and therefore risk) throughout the Site. The relationships between RAL concentrations and resulting site-wide spatially-area weighted average concentrations (SWACs) or “RAL curves” were developed by plotting acres remediated against the post remediation surface weighted average surface sediment concentration. RAL curves for each focused COC are presented in Figures 10 through 16 in Appendix I. Each point on the RAL curve corresponds to RALs for a specific alternative.

The COC-specific RALs decrease from Alternatives B through H; therefore, the areas that are capped and/or dredged increase in acres from Alternatives B through H. A summary of RALs for the focused COCs used to develop Alternatives B through H are presented in Table 18 in Appendix II. Alternative I is a combination of different RAL values plus PTW applied in specific areas of the Site. The RALs for Alternative I are presented in Table 19 in Appendix II.

Alternatives B through D include containment and removal inside the SMA footprints (sediment concentrations greater than the RALs), in-situ treatment in depositional areas where PTW is present, and removal of PTW that is NAPL or not reliably contained. Where PTW that is NAPL or not reliably contained cannot be fully removed, a significantly augmented reactive cap would be placed over the remaining material. Since Alternatives E through I address all PTW through capping and dredging, it is not necessary to include in-situ treatment in areas beyond the RAL footprints, although in-situ treatment is used as a component of caps and post-dredge residual management layers in some parts of the Site where PTW is located below feasible depths of dredging. SMAs for Alternative I are the combination of PTW areas and the RALs presented in Tables 18 and 19 in Appendix II and are shown on Figure 17 in Appendix I.

#### **10.1.1. Common Elements of the Alternatives**

The following components are included in each alternative, except for Alternative A, No-Action.

##### **10.1.1.1. Containment**

Containment or caps are designed to reduce unacceptable risk through: (1) physical isolation of the contaminated sediment or river bank soil to reduce exposure due to direct contact and to reduce the ability of burrowing organisms to move contaminants to the surface; (2) stabilization and erosion/scour protection to reduce re-suspension or erosion/scour of contaminated sediment and transport to other areas; and/or (3) chemical isolation of contaminated sediment and groundwater flux to reduce exposure from contaminants in the biologically active zone (pore water area) and contaminants transported through sediment into the water column.

Caps require monitoring and maintenance in perpetuity to ensure that the cap is performing successfully. They are generally constructed of granular material, such as fine-grained sediment, sand, or gravel, but can also include other materials with more complex designs. Five types of caps were identified for use in areas suitable for capping:

- **Engineered Caps:** These involve placing layers of materials, including but not limited to sand, coarse gravel, or clay of different thickness to isolate and prevent movement of contamination. The type of material for the layers and their thickness is dependent on the type of contaminants, their concentrations, and flow dynamics of the river. For cost estimation purposes, the FS assumed a 3-ft thick engineered cap. Final cap thickness is dependent on area-specific considerations that will be addressed in remedial design.
- **Armored Caps:** Certain areas in the river may require armoring (for example, placement of large rocks) on caps to reduce erosion, particularly during large storm events. For cost estimation purposes, the FS assumed 2-ft of sand and 1-ft of armor stone. Re-deposition of fine-grained material in capped and armored areas is anticipated to occur over time,

making the armored areas similar in surface grain size to non-armored areas. Over time, the re-colonized benthic community will likely be similar to the benthic community currently in the lower Willamette River.

Armored caps are also necessary in the shallow regions of the Site where wind and wake waves would erode the surface of an engineered cap. However, this region is also located within an area of the river that provides important habitat and placing large armor stone in this region would degrade the habitat and attract predators, which would require a large amount of mitigation. Adverse impacts on overall habitat existence and functions are important considerations during cap design and implementation. Under the CWA, avoiding or minimizing impacts to the aquatic environment from the cleanup action is a requirement. Therefore, it has been assumed that an engineered beach mix layer should be applied to the uppermost layer of all caps in areas where the minimum water depth above the cap will be < 20 feet, approximately. This beach mix layer will provide a material similar to the natural existing river bottom to minimize habitat impacts from the cleanup actions and help to stabilize the cap. The specifications for armoring material will be determined during remedial design based on: a Site-specific analysis of erosion potential; analysis of minimizing impacts to the aquatic environment; and consultation with the appropriate resource agencies regarding effects on critical habitat, if relevant.

- **Reactive Caps:** Chemical isolation of contaminated sediment by capping may require an additional reactive layer of amendments such as activated carbon or organoclay when it is predicted that flow of groundwater or pore water will release contamination through the cap. In these instances, the ability of the cap material and amendments to contain contaminants will determine the ability to prevent contaminant movement through the cap. If sediment classified as containing highly toxic PTW is located in an area designated for capping, then a reactive cap was assumed for that area. All areas, including river banks, with known discharges of contaminated groundwater are assumed to require an in-river reactive cap to reduce the contaminant movement and limit potential exposures. The type and quantity of reactive material utilized in reactive caps will be determined during remedial design based on cap modeling and other information.
- **Armored Reactive Cap:** Within certain areas in the river where reactive caps are needed, armoring to reduce erosion, particularly during large storm events may also be necessary. The armored reactive cap design concept was assumed for both shallow and intermediate regions.
- **Significantly Augmented Reactive Cap:** In areas where NAPL or PTW that cannot be reliably contained remains in the river either due to the depth of contamination or the presence of structures that preclude removal, organoclay reactive layers in conjunction with low permeable materials are assumed in the cap design. Organoclay has recently been used as an amendment in the capping of NAPL at the McCormick and Baxter site in the Willamette River within the Site. The use of low permeability materials in combination with a reactive layer is expected to further retard contaminant migration.

#### 10.1.1.2. In-Situ Treatment

In-situ treatment of sediment refers to chemical, physical, or biological techniques for reducing contaminant concentrations, toxicity, bioavailability, or mobility while leaving the contaminated sediment in place. Given the NCP's expectation for treatment of PTW, in-situ treatment technologies are considered for the PTW areas. In-situ treatment is also considered in areas where groundwater plumes impact pore water.

Treatment options considered include in-situ solidification/stabilization and sequestration, which may be used to address PTW underneath and around pilings, docks, berthing or mooring dolphins, and other structures servicing active wharfs or shore-based facilities that remain intact. Amendments to caps or residual layers such as activated carbon or organoclay mats increases the ability to absorb certain types of organics and metals. The effectiveness of these amendments is dependent on the initial COC concentrations and the mixture of COCs present. Amendments can be engineered to facilitate placement in aquatic environments.

In the federally-authorized navigation channel and future maintenance dredge (FMD) areas, in-situ treatment alone is not compatible with current or future uses since future maintenance dredging would remove any material placed; thus, in-situ treatment is not generally considered to be effective over the long term or implementable in these areas unless these materials are placed below the authorized dredge depth with an overdredge allowance/buffer zone. In-situ treatment is used in residual layers after dredging where PTW is left in place or where groundwater plumes may impact pore water. In intermediate, shallow and river bank regions of the Site where PTW is left in place, either in-situ treatment or amendments to caps and post-dredging residual layers will be implemented.

#### 10.1.1.3. Removal

Removal of contaminated sediment can be accomplished while submerged (dredging) or during low water levels or after water has been diverted or drained (dry excavation). For purposes of FS cost estimates, mechanical dredging and excavation from off-shore rigs was assumed for sediment and river bank soil removal. The most appropriate and effective method to remove sediment and river bank soils will be determined during remedial design. Dredged or excavated sediment/soil will be placed on a barge and transported to a staging or handling area for dewatering and pretreatment, treatment, or final disposal. Several modes of transportation may be used to move dredged or excavated sediment depending on the dredge location(s), volume of sediment, whether it needs pretreatment, and the final disposal location.

If contamination at concentrations greater than the RALs extends below the maximum dredge depth, a cap will be placed over the remaining contamination. Otherwise, a residual sand layer will be placed over the dredged area and within the prism and surrounding area that may have been impacted by dredge residuals to cover the exposed surface and isolate any dredge residuals and remaining contaminated sediment.

Several major considerations drive the design concept, cost estimates, and feasibility evaluation for the dredging included in the remedial alternatives for the FS, such as the following:

- **Mechanical Removal Equipment:** Environmental/closed buckets were assumed in the FS to be used to lessen releases to the water column. Articulated fixed-arm dredges would be the preferred dredging option due to the greater bucket control that can be achieved versus cable-operated dredges. This greater bucket control has proven to limit contaminant resuspension and release at other sediment sites. Articulated fixed-arm dredges were assumed to have a maximum arm reach of 50 ft and bucket sizes range from approximately 2 cy to 6 cy.
- **Productivity:** The duration of the dredging season was assumed to be 122 days based on an in-river fish work window established for the Willamette River of July 1 through October 31. This in-river work window accounts for fish migration patterns of threatened or endangered species and may be refined following discussions with the relevant technical experts from the natural resource agencies. Dredging and excavation operations were assumed to occur 24 hours/6 days per week.
- **Volume Estimates:** Limited data exist on the depth of contamination at the Site. Actual dredge depths will be based on data collected during remedial design and the RALs. A maximum dredge depth of 15-19 ft<sup>9</sup> was assumed in the intermediate and Nav/FMD Regions and in the shallow regions where PTW that is NAPL or not reliably contained is present since deeper dredge depths would require special design and side slope stabilization considerations. A maximum dredge depth of 5 ft in the rest of the shallow regions was assumed because contaminant concentrations greater than RALs in this area of the Site are generally less than 5 ft.
- **Potential Contaminant Release during Construction:** Release is the mechanism by which dredging operations result in transfer of contaminants from sediment pore water and sediment particles into the water column or air. Dredging BMPs, such as silt curtains or sheet pile walls, will be used to minimize releases to the water column. Monitoring of water quality parameters will be conducted to measure the effectiveness of these controls and to determine whether additional control measures may be required. The monitoring program will include surface water and air (where necessary).
- **Dredge Residuals:** Residuals are contaminated sediment remaining in or next to the dredged footprint. Managing dredge residuals through the placement of clean material soon after dredging is an important BMP for minimizing releases of contaminants, including resuspension. If contamination above the RALs extends below the maximum dredge depth, a cap will be placed over the residual contamination. Otherwise, a 12-inch sand layer was assumed to be placed, as needed, over all dredge areas to cover the exposed surface and isolate any dredge residuals and remaining contaminated sediment inventory. The placement of 12 inches of sand would eliminate the need for additional dredge passes

---

<sup>9</sup> Based on available information, nine acres of the Site have contamination greater than cleanup levels at depths greater than 15 ft located in the navigation channel, FMD, and intermediate areas of the Site. Due to the very small volume that this creates and that an over-dredge of 3 to 5 feet would need to be made to place a cap in these areas due to current and future uses, these over-dredge depths were included in the dredge volume calculations.

and ensures that the leave surface is clean. In areas where PTW is present post dredging, 5% activated carbon was assumed to be mixed with the cap.

- **Buried Debris and Pilings:** Buried debris may impede removal of contaminated sediment and river bank materials at the Site, so they will be removed. Additionally, debris may impede appropriate application of caps. A standard clamshell bucket, grapple, or equivalent will be used for debris removal. Appropriate controls specifically designed for debris or structure removal will be used to minimize releases and dredge residuals.
- **Flood Rise Concerns:** A simple evaluation balancing the amount of sediment removed and the amount placed into the river was conducted in Appendix P of the FS. A Hydrologic Engineering Center River Analysis System (HEC-RAS) model will be run on the Selected Remedy to ensure that flood rise management complies with regulatory requirements throughout the Site. This model will be run on both smaller and larger scales in order to assess the flood-rise impacts of the cleanup.
- **Material Handling:** Dredged material was assumed to be loaded directly into barges and transported for dewatering, treatment, or further transport. River bank materials excavated from above the water line were assumed to be loaded directly into containers or barges for transport and treatment as needed.

#### 10.1.1.4. Disposed Material Management

Two options for disposal of dredged material were analyzed in the FS: (1) off-Site commercial landfills (RCRA Subtitle C and D) and (2) a CDF. Sediment dredged from the Site will require characterization to determine whether it should be classified as material containing hazardous waste under RCRA or state hazardous waste law.

- **Off-Site Commercial Landfills:** A RCRA Subtitle C facility that accepts hazardous waste was used in the FS evaluation and for costing purposes, such as Chemical Waste Management of the Northwest (Chem Waste) Landfill. A RCRA Subtitle D facility that accepts non-hazardous waste was used in the FS evaluation and for costing purposes, such as Roosevelt Regional Landfill.
- **On-Site CDF:** A CDF is an engineered structure, typically built on land adjacent to the water and extending into the waterbody (on the sediment bed) to store contaminated dredged material, isolating it from the surrounding environment. An in-river CDF may be constructed with sheet pile walls or other containment structures such as berms, either against the shore or as an island. Once an in-river CDF is filled, it would be capped, converting open water to dry land. CDFs have been proven to be a viable disposal option at other Superfund sediment sites. They can be a technically viable and cost effective means to dispose of contaminated sediment. In addition, a CDF is more efficiently integrated with dredging because transporting and offloading dredged material to a CDF causes fewer short-term impacts to the community and would be more cost-effective than transporting and offloading to an off-site landfill. The option to construct a CDF is dependent on the volume of dredged sediment. The CDF selected for FS evaluation and

costing purposes is the Terminal 4 CDF, with a capacity of approximately 670,000 cy of non-hazardous waste.

Using these two options, two disposal scenarios were developed that consider regulatory requirements governing disposal, sediment contaminant characteristics, and disposal capacity compared to volume of dredged sediment for each alternative. Under RCRA, dredged material that is handled consistent with the CWA Section 404 is exempt from hazardous waste characterization and management requirements, but if such dredged material is taken off-site for disposal, RCRA characterization would apply. The expected regulatory waste types that may be generated through dredging include waste that may contain RCRA characteristic hazardous wastes, RCRA- and state-listed hazardous wastes, and Toxic Substances Control Act (TSCA) waste. Additionally, dredged material that is not regulatory waste but has high concentrations or other characteristics requiring special disposal considerations will include “Waste or Media containing Waste that May Warrant Additional Management” and PTW. Information about each of these waste types and their special handling and disposal requirements are discussed in the FS.

- **DMM Scenario 1 - Confined Disposal Facility and Off-Site Disposal:** This scenario would allow the disposal of dredged material in a CDF and off site. This scenario was only applied to Alternatives E through I because the estimated dredged material volumes under these alternatives meet the minimum volume needed to justify construction of a CDF, which is approximately 670,000 cy. Waste meeting the CDF disposal requirements would be placed in the CDF. Waste that does not meet the CDF requirements would be disposed of at an off-site RCRA Subtitle C or D facility. Acceptance criteria for the sediment placed in the CDF include: no RCRA or state hazardous waste, no “Waste or Media containing Waste that May Warrant Additional Management”, no PTW that is highly mobile, no free oil, no debris or significant organic material, no contaminants that would leach out of the CDF, and other considerations such as the physical nature of the material, the nature of the chemical contaminants, and the quantity of material. More information on the CDF acceptance criteria is provided in the FS.
- **DMM Scenario 2 - Off-Site Disposal:** This scenario applies to all alternatives. All dredged material will be disposed of in an off-site landfill (RCRA Subtitle C or D facility). Non-hazardous dredged materials (as defined under RCRA) are eligible for direct landfill disposal at a RCRA Subtitle D facility if in compliance with the individual acceptance criteria of the receiving facility. Dredged material containing a hazardous waste is eligible for direct landfill disposal at a RCRA Subtitle C or D (if treated) facility, if the material is in compliance with the individual acceptance criteria of the receiving facility. The capacity of the Roosevelt Regional RCRA Subtitle D facility and the Chem Waste RCRA Subtitle C Landfill is essentially unlimited relative to the volume of sediment expected to be dredged from the Site.

For both DMM scenarios, land-based disposal typically requires dewatering, waste water treatment, and transport to the disposal site via land based or water based transportation. Material that may need to be treated is assumed to be treated at a nearshore upland facility that will be sited

and constructed in remedial design. To minimize the impact to surrounding communities, dredged material was assumed to be transported by barge to either the off-site facility or to the CDF. Currently, there is no existing transfer facility within the Site to facilitate off-site disposal.

#### 10.1.1.5. Ex-Situ Treatment

Ex-situ treatment would involve the application of chemical, physical or biological technologies to transform, destroy, or immobilize contaminants following removal of contaminated sediment. Depending on the contaminants, their concentrations, and the composition of the sediment, treatment of the sediment to reduce the toxicity, mobility, or volume of the contaminants before disposal may be warranted. Available disposal options and capacities may also affect the decision to treat some sediment. In general, treatment processes have the ability to reduce sediment contaminant concentrations, mobility, and/or toxicity by: (1) contaminant destruction or detoxification, (2) extraction of contaminants from sediment, (3) reduction of sediment volume, or (4) sediment solidification/stabilization. Regulatory requirements determine the need to treat some sediments (such as RCRA Land Disposal Restrictions [LDR]); therefore, treatment has been considered. Prior to disposal, an evaluation of dredged sediment containing any RCRA hazardous wastes, pesticide residue, or MGP waste subject to the 2004 dispute decision, will be conducted to determine the need for, and extent of, treatment appropriate for the off-site disposal requirements.

Low temperature thermal desorption and solidification/stabilization are ex-situ treatment options considered in the FS for the Site, although other treatment options were retained and may be considered during remedial design. Low temperature thermal desorption has been demonstrated at other sediment remediation sites, is effective for SVOCs and PAHs, but has limited effectiveness for PCBs. An acid scrubber was assumed to treat off-gas of thermally-treated material. Solidification/stabilization has been effectively used for Gasco wastes and effective at reducing the mobility of contaminants. Fine-grained sediment and high moisture content will increase treatment times and volumes. Commercial technologies are widely available for both on-site and off-site applications of these treatment options.

#### 10.1.1.6. Monitored Natural Recovery

Natural recovery uses ongoing, naturally occurring processes to contain, destroy, or reduce the bioavailability or toxicity of contaminants in sediment. These processes may include physical (sedimentation or dispersion), biological (biodegradation), and chemical (sorption and oxidation) mechanisms that act together to reduce the risks posed by contaminants. At this Site, it is expected that physical isolation through natural deposition of cleaner material coming in from upstream and dispersion and mixing are the primary mechanisms for natural recovery. Analysis of upstream suspended sediment data suggests incoming sediment COC concentrations are lower than sediment concentrations measured at the Site. Therefore, when the cleaner sediment is deposited on and mixed into the contaminated surface sediment within the Site, the overall contaminant concentration in the surface sediment is reduced, thus reducing the exposure to the contamination. The effectiveness of MNR will be dependent in large part on the surface sediment concentration and the concentration and rate of deposition and mixing of the cleaner

sediment. Several lines of evidence (LOE) were evaluated in Section 8 of Appendix D in the FS to determine the processes and areas where MNR would be effective. LOEs evaluated included deposition and erosion rates; consistency of depositional and erosional processes; sediment grain size; anthropogenic factors; the subsurface to surface sediment concentration ratio; and wind and wake-generated waves.

Natural recovery mechanisms (Magar et al 2009), including chemical transformation, reduction in contaminant mobility and bioavailability, physical isolation (or burial), and dispersion, will all be occurring to varying degrees throughout the Willamette River. Burial is a primary mechanism for natural recovery. Over time, cleaner sediment deposits on top of more contaminated sediment, lessening the contaminant exposures to organisms.

Deposition is well documented in areas of the Willamette River. A clear example of the depositional nature of areas of the harbor is the need for routine navigation dredging. Location-specific determinations of deposition can also be obtained from analyzing bathymetric surveys. A series of high resolution bathymetric surveys were conducted within the Site at five different times between 2002 and 2009 (Jan 2002, July/September 2002, May 2003, February 2004, and January 2009). These surveys were evaluated during the FS.

The draft FS also contained several other LOE for natural recovery, including grain size and modeling predictions. That analysis assessed natural recovery averaging over 1-mile long river reaches and indicated that natural recovery would be effective over most of the Site, except it was less certain in RMs 6-8, and may not occur in RM 11.8-11 and Swan Island Lagoon.

Fish tissue concentrations that were sampled over time were also evaluated to determine whether they can indicate MNR processes. An exact comparison between sample years is not possible because sampling and compositing schemes vary between years, but comparison of the 2012 data to the 2007 data (most similar in sampling protocol) is suggestive of declines in PCB concentrations in the system at some locations in the harbor. These declines likely resulted from natural recovery as well as source control efforts. The 2012 fish tissue data will serve as an excellent comparator in future evaluations of declines in PCB concentrations in fish tissue.

Combined, the information indicates that recovery is occurring in the system, likely through a combined effect of natural processes, source control efforts, and remedial actions to date.

MNR does not include active remedial measures. However, it does include monitoring to assess whether these natural processes continue to occur and the rate they may be reducing contaminant concentrations in surface sediment. Monitoring of the surface water, sediment, and fish tissue will be used to determine the progress of MNR to achieve RAOs and cleanup levels.

#### 10.1.1.7. Enhanced Natural Recovery

In areas where natural recovery is occurring, but not at a rate sufficient to reduce risks within an acceptable time frame, enhancement or acceleration of the recovery process by engineering means can be considered. ENR at this Site is accomplished by adding a thin-layer cover of clean sand over contaminated sediment to accelerate natural recovery. The acceleration can occur through several processes, including increased dilution of contaminant concentrations in

sediment from mixing, thereby decreasing the exposure of organisms to contaminants. Areas that are not erosional or are naturally recovering slowly are candidates for ENR. ENR with a thin-layer placement of sand is different than the caps used to isolate contaminants.

ENR will be accomplished through the placement of a sand layer, assumed in the FS to be 12 inches, which is expected to be sufficient to allow mixing with the underlying sediment bed, while also retaining a clean sand surface above the mixed layer. In areas where PTW is present, it is assumed that activated carbon will be added to the sand layer and would be monitored in perpetuity. This may be further defined during the remedial design if areas with PTW are addressed through ENR.

An analysis of data collected during the RI indicate that MNR may not be occurring in Swan Island Lagoon at a rate sufficient to reduce risks within an acceptable time frame. Water circulation is limited, which may limit the rate of sediment deposition and the entry of clean upriver sediment into this area. Since MNR is not considered a viable technology in this area, ENR was assumed for the area in Swan Island Lagoon that is outside the areas to be dredged or capped in order to meet the cleanup levels within an acceptable time frame. This limits the need to apply dredging and capping to larger areas of Swan Island Lagoon to meet cleanup levels in an acceptable time frame. Appendix D of the FS provides an analysis of the trade-offs between ENR and dredging/capping a larger area within Swan Island Lagoon.

#### 10.1.1.8. Institutional Controls

The objectives of ICs are to prevent exposure to contaminants on both a short-term and long-term basis until protective levels are achieved for all populations and to maintain the integrity of the engineered components of the remedy. ICs will include fish consumption advisories, educating the community by conducting an enhanced community outreach program, and limiting other river use activities during and after implementation of the remedy. ICs will also be used to protect caps in perpetuity by limiting one or more waterway and land use activities that may disturb or reduce the cap's ability to contain the contaminated sediment or groundwater. Other types of controls that likely will be used include coordinated permit reviews of in-river work (e.g., maintenance dredging, pile removal) and other government controls to minimize recontamination to the Site. More detail on the potential IC mechanisms is provided below.

- **Fish Advisories and Educational Outreach:** A fish advisory will be part of the CERCLA response. Once construction is completed, the advisory would be updated to allow an increased consumption rate based on fish tissue concentrations. The advisory may be periodically updated until RAOs and cleanup levels are reached. The outreach program may include: informational meetings, presentations, and workshops targeting affected community groups; development and distribution of informational materials such as brochures or maps; advisory notifications communicated through a variety of culturally appropriate outlets; installation and maintenance of advisory signs at known fishing locations; and coordination with sport or recreational fishing clubs and licensing locations.
- **Waterway Use Restrictions or Regulated Navigation Areas (RNAs):** Where caps will be utilized to contain contamination in navigable areas of the river, waterway use

restrictions will be necessary to ensure the integrity of the cap is maintained in perpetuity. These restrictions, depending on the Site-specific circumstances, may preclude boat anchoring and keel dragging, the use of spuds to stabilize vessels, structure and utility maintenance and repair, and future maintenance dredging in areas containing caps. Notifications such as signs and buoys may be used to warn vessels away from the area. RNAs have been successfully used in the past to protect remedial actions at the McCormick and Baxter cap and the Gasco interim action cap from vessel activities. Periodic inspections of waterway use restrictions will be needed to ensure they are functional and effective and will be evaluated in 5-year reviews.

- **Land Use/Access Restrictions:** Land use or access restrictions may also need to be implemented in nearshore areas and river banks to maintain the integrity of caps and/or mitigation areas from existing or future activities, such as construction and maintenance of structures. The Oregon DSL has control of state-owned submerged or submersible land that may be subjected to remedial action. Adjacent landowners also may control submerged land and river banks. Coordination with DSL and adjacent landowners would be needed to implement any land use or access restrictions. Monitoring, including inspections, will be needed to ensure that restrictions are functioning as intended and will be evaluated in statutory 5-year reviews.
- Additional IC mechanisms that can accomplish the IC objectives may be analyzed and implemented during remedial design and remedial action. IC mechanisms will be developed during remedial design.

#### 10.1.1.9. Monitoring

Monitoring is an integral component of all alternatives and will be conducted to evaluate short- and long-term effectiveness. The monitoring program will include analysis of sediment, river banks, surface water, pore water, fish tissue, and air (before, during, and after construction):

- New baseline sampling and monitoring will be conducted prior to implementation of remedial activities to establish current baseline conditions (pre-construction), to delineate construction areas, and to evaluate construction activities and the performance of the remedy. This will include a statistically valid collection (95% UCL) of data of both surface and subsurface sediment concentrations in and near where contamination was identified in the RI/FS and has come to be located for the purposes of applying ROD decision trees and proceeding with the design of active remediation throughout the harbor. Data will be collected consistent with EPA-approved RI/FS decision rules on data collection (e.g., treatment of a non-detect value) and will be evaluated on spatial and temporal scales appropriate for the RAOs.
- Short-term monitoring will be conducted during construction and post construction until remedial action performance goals and cleanup levels are met.
- Long-term monitoring will be conducted periodically after cleanup levels are met where waste is left in place to ensure the remedy is still protective of human health and the

environment. Statutory five-year reviews of the remedy will be conducted until unlimited use/unlimited exposure for the whole Site is achieved.

#### 10.1.1.10. ARARs

CERCLA requires remedial actions to comply with ARARs or waive them. The following are the key ARARs associated with the remedial alternatives presented below:

- Federal NRWQCs, if more stringent than a promulgated Oregon numeric water quality standard, are both cleanup levels for surface water and groundwater discharging to the river, and they are action-specific standards for minimizing discharges of contaminants during construction.
- Oregon WQs contain both promulgated numeric and narrative water quality standards that protect the designated uses of the river. Relevant numeric standards are cleanup levels for surface water and groundwater discharging to the river, and numeric and narrative water quality standards are action-specific standards for minimizing discharges of contaminants during construction.
- MCLs and non-zero MCLGs established under the authority of the SDWA as both cleanup levels for surface water and groundwater discharging to the river, and as action-specific standards for minimizing discharges of contaminants during construction.
- OHSRA set standards for the degree of cleanup required for hazardous substances by establishing acceptable risk levels for human health at  $1 \times 10^{-6}$  for individual carcinogens,  $1 \times 10^{-5}$  for multiple carcinogens, and an HI of 1 for noncarcinogens.
- Federal and state solid and hazardous waste regulations such as the RCRA, including LDRs, and TSCA set handling, characterizing, treating, and disposing of dredged sediment off-site.
- The ESA, because threatened or endangered species migrate through and use the Site and the Site contains designated critical habitat for such species, requires reasonable and prudent measures to minimize adverse effects on the species and critical habitat from implementation of the remedy, including the time of year and duration in-river work can be conducted.
- Section 404 of the CWA, because all of the action alternatives result in the discharge of dredged or fill material to waters of the US to some degree, requires the remedy to avoid or minimize impacts to the aquatic environment and to mitigate unavoidable impacts.
- Section 401 of the CWA, because each action alternative will result in the discharge of pollutants to waters of the US to some degree, requires reasonable assurances that the activity will be conducted in a manner which will not violate applicable water quality standards by the imposition of any effluent limitations, other limitations, and monitoring requirements.

- Section 10 of the Rivers and Harbors Act, because creation of any obstruction not affirmatively authorized by Congress to the navigable capacity of any waters of the United States is prohibited, requires that no obstruction to navigation can be created by any of the alternatives.
- Federal Emergency Management Agency (FEMA) floodplain regulations prohibit encroachments that would result in any increase in flood levels during occurrence of base flood discharge and require measures to reduce the risk of flood loss, minimize the impact of floods, and restore and preserve the natural and beneficial values of floodplains.

#### 10.1.1.11. Costs

Cost estimates were developed in the FS for each remedial action alternative based on the RI data to define the scope of each alternative. The types of costs estimated include the following: (1) capital costs, including both direct and indirect costs; (2) annual O&M costs; and (3) net present value of capital and O&M costs (40 Code of Federal Regulations (CFR) 300.430 (e)(9)(iii)(G)). A discount rate of 7% was used in the present value calculations, consistent with EPA guidance. Remedial action alternative cost estimates for the detailed analysis are intended to provide a measure of total resource costs over time (“life cycle costs”) associated with any given alternative. Cost estimates for detailed analysis of alternatives were developed with expected accuracy ranges of -30 to +50% of actual cost, as identified in the NCP. Detailed costs estimates are included in the FS.

#### 10.1.2. Application of Technologies by River Region

The majority of the alternatives developed combine all the technologies described above. Determining the appropriate technology to assign to a specific area of the river is dependent on a number of area-specific characteristics and environmental conditions. These factors include contaminant concentrations, current and reasonably anticipated future land and waterway use, areas of erosion/deposition, sediment bed slope, infrastructure such as docks and piers, and physical sediment characteristics. In areas to be dredged or capped, a technology assignment process (FS Figures 3.8-1-b and 3.8.1-c) identifies either capping or dredging for each area. After identifying appropriate cap or dredge technologies through this process, further modifications may be necessary during design to ensure the final constructed remedy is appropriate for the actual Site conditions. The technology assignment is also based on the river regions shown in Figure 18 in Appendix I and explained in more detail in FS Figures 3.8-1a-d decision trees. The primary difference between the alternatives is the size of the SMA footprints shown on Figures 19a-h in Appendix I. Based on the CSM, areas with levels of contamination greater than the RALs where MNR would not be effective in reducing contaminant levels and ultimately risks, were assigned dredging or capping. The summary of the areas of each assigned technology in the FS is presented in Table 20 in Appendix II. MNR will be applied to areas of low-level contamination.

## 10.2. Remedial Alternatives

EPA developed nine remedial alternatives for the Site that address the RAOs, consider the requirements of CERCLA and the NCP, and consider the large, complex nature of the Site. The remedial alternatives were assembled by combining the retained remedial technologies described above.

Remedial alternatives include the No Action alternative (designated as Alternative A), as required by the NCP, and eight remedial alternatives (designated as Alternatives B through I) that apply the same suite of remedial technologies to varying degrees based on Site-specific characteristics. A summary of the Alternatives is presented below. It should be noted that dredged areas increase in acreage from Alternatives B through H. A summary of RALs for the focused COCs used to develop Alternatives B through H are presented in Table 18 in Appendix II. Alternative I uses a combination of different RAL values and PTW applied in specific areas of the Site. The RALs for Alternative I are presented in Table 19 in Appendix II. Table 20 in Appendix II summarizes the number of acres assigned to each technology.

Alternatives A through G were the first set of Alternatives developed in drafting the FS. However, following Tribal consultations and meetings with the CAG, EPA developed Alternative H, which reaches cleanup levels at the end of construction by capping/dredging the entire Site. Additionally, as EPA was evaluating the alternatives, EPA determined that none of the Alternatives achieved a consistent level of risk reduction throughout the Site after construction. In order to achieve consistent risk reduction throughout the Site, EPA developed Alternative I which uses a different combination of the technologies used in Alternatives B through F while ensuring that all PTW is addressed. Alternative C was screened out because it was so similar to Alternative B. When constructed, the difference between Alternatives B and C was negligible. Alternative H was also screened out due to implementability and cost considerations.

Detailed information about the remedial alternatives is provided in the FS Report and in FS Table 4.3-1.

### 10.2.1. Alternative A: No Action

Capital Costs:	\$0
Periodic Costs:	\$0
Present Value:	\$0
Construction Duration:	0 years

The Superfund program requires that the No Action alternative be considered as a baseline for comparison with the other alternatives. The No Action alternative would not include any remedial measures beyond the early actions implemented at the Gasco and Terminal 4 sites in 2005 and 2008, respectively. OHA may continue to implement the fish consumption advisories already in place under state legal authorities, but it is not part of the CERCLA response. The No Action Alternative does not include implementation of any new ICs or monitoring as a part of a CERCLA action for the Site.

### 10.2.2. Alternative B

Capital Costs:	\$352,097,000
Periodic Costs <sup>10</sup> :	\$290,324,000
Present Value:	
With DMM Scenario 2:	\$451,460,000
Construction Duration:	4 years

Alternative B uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would only support DMM Scenario 2 – off-site disposal, since this alternative would not generate enough dredged material to justify constructing a CDF.

Alternative B would have a total constructed area of 201 acres of sediment and 9,633 lineal ft of river bank, would allow 1,966 acres of sediment to naturally recover, and would not address 20,416 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 95.0 acres of contaminated sediment, 99.8 acres of ENR and 6.7 acres of in-situ treatment. Additionally, 9,633 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

#### *Site Wide*

- Dredging (different depths): 72.2 acres - 494,000 to 659,000 cy of sediment
- Excavation: 51,000 cy of soil
- Capping area: 22.8 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 6.7 acres
- ENR: 99.8 acres
- MNR: 1,966 acres

The design concept for Alternative B is shown on Figure 20 in Appendix I.

Construction Duration: This alternative would take an estimated 4 years of construction, with no additional time required to complete dredged material processing (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

---

<sup>10</sup> Periodic costs include Operation and Maintenance (O&M) costs and 5-year review costs over 30 years.

- Year 0<sup>11</sup>: Establish initial conditions
- Year 0<sup>12</sup>: Construction of on-site material handling/treatment facility (if applicable)
- Year 0<sup>13</sup>: Start-up activities and mobilization, including pre-design investigations
- Years 1 and 2: In-river construction
- Year 3: Demobilization and mitigation

Disposal: Under Alternative B, an estimated volume of 494,000 to 659,000 cy of dredged material would be managed under DMM Scenario 2.

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also discussed in Common Elements of the Alternatives.

### **10.2.3. Alternative C**

Capital Costs:	\$400,933,000
Periodic Costs:	\$317,464,000
Present Value:	
With DMM Scenario 2:	\$496,760,000
Construction Duration:	5 years

This alternative was screened out since it was essentially the same constructed alternative as Alternative B.

Alternative C uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would only support DMM Scenario 2 – off-site disposal, since this alternative would not generate enough dredged material to justify constructing a CDF.

Alternative C would have a total constructed area of 219 acres of sediment and 11,047 lineal ft of river bank, would allow 1,948 acres of sediment to naturally recover, and would not address 19,002 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 116.8 acres of contaminated sediment, 97.4 acres of ENR and 5.0 acres of in-situ treatment. Additionally, 11,047 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

---

<sup>11</sup> Monitoring (sampling) of sediment, water, biota, groundwater, and pore water will need to be the first phase, and it will encompass the entire Site to establish a baseline and delineate the SMAs for construction. It is expected that this phase will take 3 to 5 years.

<sup>12</sup> If a location for an on-site material handling/treatment facility is determined, construction of the facility would occur prior to construction activities.

<sup>13</sup> Year 0 is the first year of construction.

*Site Wide*

- Dredging (different depths): 86.6 acres - 592,000 to 790,000 cy of sediment
- Excavation: 58,000 cy of soil
- Capping area: 30.2 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 5.0 acres
- ENR: 97.4 acres
- MNR: 1,948 acres

The design concept for Alternative C is shown on Figure 21 in Appendix I.

Construction Duration: This alternative would take an estimated 5 years of construction, with no additional time required to complete dredged material processing (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization including pre-design investigations
- Years 1 through 3: In-river construction
- Year 4: Demobilization and mitigation

Disposal: Under Alternative C, an estimated volume of 592,000 to 790,000 cy of dredged material would be managed under DMM Scenario 2.

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also discussed in Common Elements of the Alternatives.

**10.2.4. Alternative D**

Capital Costs:	\$556,004,000
Periodic Costs:	\$397,028,000
Present Value:	
With DMM Scenario 2:	\$653,700,000
Construction Duration:	6 years

Alternative D uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative only supports DMM Scenario 2 – off-site disposal, since this alternative would not generate enough dredged material to justify constructing a CDF.

Alternative D would have a total constructed area of 267 acres of sediment and 13,887 lineal ft of river bank, would allow 1,900 acres of sediment to naturally recover, and would not address 16,161 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 176.9 acres of contaminated sediment, 87.0 acres of ENR, and 3.2 acres of in-situ treatment. Additionally, 13,887 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

#### *Site Wide*

- Dredging (different depths): 132.1 acres - 950,000 to 1,266,000 cy of sediment
- Excavation: 73,000 cy of soil
- Capping: area: 44.8 acres
- Ex-situ treatment: 156,000-208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 3.2 acres
- ENR: 87.0 acres
- MNR: 1,900 acres

The design concept for Alternative D is shown on Figure 22 in Appendix I.

Construction Duration: Alternative D would take an estimated 6 years of construction, with no additional time required to complete dredged material processing (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization, including pre-design activities
- Years 1 through 4: In-river construction
- Year 5: Demobilization and mitigation

Disposal: Under Alternative D, an estimated volume of 950,000 to 1,266,000 cy of dredged material would be managed under DMM Scenario 2.

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also discussed in Common Elements of the Alternatives.

#### **10.2.5. Alternative E**

DMM Scenario 1:

Capital Costs: \$748,071,000

Periodic Costs:	\$412,332,000
Present Value:	\$804,120,000
DMM Scenario 2:	
Capital Costs:	\$827,465,000
Periodic Costs:	\$412,332,000
Present Value:	\$869,530,000
Construction Duration:	7 years

Alternative E uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would support DMM Scenario 1 – off-site disposal and CDF and DMM Scenario 2 – off-site disposal. This alternative would generate enough dredged material to justify constructing a CDF.

Alternative E would have a total constructed area of 329 acres of sediment and 18,231 lineal ft of river bank, would allow 1,838 acres of sediment to naturally recover, and would not address 11,817 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 269.3 acres of contaminated sediment and 59.8 acres of ENR. Additionally, 18,231 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

#### *Site Wide*

- Dredging (varying depths): 203.7 acres -1,653,000 to 2, 204,000 cy of sediment
- Excavation: 96,000 cy of soil
- Capping: area: 65.6 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 0 acres
- ENR: 59.8 acres
- MNR: 1,838 acres

The design concept for Alternative E is shown on Figure 23 in Appendix I.

Construction Duration: Alternative E would take an estimated 7 years of construction, with no additional time required to complete processing of dredged material (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization, including pre-design investigation
- Years 1 through 5: In-river construction

- Year 6: Demobilization and mitigation

Disposal: The material removed from the Site under Alternative E would be managed in one of two disposal scenarios:

- DMM Scenario 1:
  - 670,000 cy to the onsite CDF
  - 983,000 to 1,534,000 cy to off-site disposal facilities in compliance with the off-site rule
- DMM Scenario 2:
  - 1,653,000 to 2,204,000 cy to off-site disposal facilities in compliance with the off-site rule

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also discussed in Common Elements of the Alternatives.

**10.2.6. Alternative F**

DMM Scenario 1:

Capital Costs:	\$1,550,014,000
Periodic Costs:	\$549,512,000
Present Value:	\$1,316,560,000

DMM Scenario 2:

Capital Costs:	\$1,629,407,000
Periodic Costs:	\$549,512,000
Present Value:	\$1,371,170,000

Construction Duration: 13 years

Alternative F uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would support DMM Scenario 1 – off-site disposal and CDF and DMM Scenario 2 – off-site disposal. This alternative would generate enough dredged material to justify constructing a CDF.

Alternative F would have a total constructed area of 533 acres of sediment and 23,305 lineal ft of river bank, would allow 1,634 acres of sediment to naturally recover, and would not address 6,477 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 505.3 acres of contaminated sediment and 28.2 acres of ENR. Additionally, 23,305 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

### *Site Wide*

- Dredging (varying depths): 387.4 acres - 3,825,000 to 5,100,000 cy of sediment
- Excavation: 123,000 cy of soil
- Capping area: 117.8 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy soil of soil
- In-situ treatment: 0 acres
- ENR: 28.2 acres
- MNR: 1,634 acres

The design concept for Alternative F is shown on Figure 24 in Appendix I.

Construction Duration: Alternative F would take an estimated 13 years of construction, with no additional time required to complete processing of dredged material (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization, including pre-design investigations
- Years 1 through 11: In-river construction
- Year 12: Demobilization and mitigation

Disposal: The material removed from the Site under Alternative F would be managed in one of two disposal scenarios:

- DMM Scenario 1:
  - 670,000 cy to the onsite CDF
  - 3,155,000 to 4,430,000 cy to off-site disposal facilities in compliance with the off-site rule
- DMM Scenario 2:
  - 3,825,000 to 5,100,000 cy to off-site disposal facilities in compliance with the off-site rule

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also provided in Common Elements of the Alternatives.

### 10.2.7. Alternative G

#### DMM1 Scenario:

Capital Costs:	\$2,421,152,000
Periodic Costs:	\$708,114,000
Present Value:	\$1,731,110,000

#### DMM Scenario 2:

Capital Costs:	\$2,500,545,000
Periodic Costs:	\$708,114,000
Present Value:	\$1,777,320,000

Construction Duration: 19 years

Alternative G uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would support DMM Scenario 1 – off-site disposal and CDF and DMM Scenario 2 – off-site disposal. This alternative would generate enough dredged material to justify constructing a CDF.

Alternative G would have a total constructed area of 776 acres of sediment and 26,362 lineal ft of river bank, would allow 1,391 acres of sediment to naturally recover, and would not address 3,686 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 756.4 acres of contaminated sediment and 19.5 acres of ENR. Additionally, 26,362 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

#### *Site Wide*

- Dredging (various depths): 571.7 acres - 6,221,000 to 8,294,000 cy of sediment
- Excavating: 139,000 cy of soil
- Capping area: 184.7 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 0 acres
- ENR: 19.5 acres
- MNR: 1,391 acres

The design concept for Alternative G is shown on Figure 25 in Appendix I.

Construction Duration: Alternative G would take an estimated 19 years of construction, with no additional time required to complete processing of dredged material (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization, including pre-design investigation
- Years 1 through 17: In-river construction
- Year 18: Demobilization and mitigation

Disposal: The material removed from the Site under Alternative G would be managed in one of two disposal scenarios:

- DMM Scenario 1:
  - 670,000 cy to the onsite CDF
    - 5,551,000 to 7,624,000 cy to off-site disposal facilities in compliance with the off-site rule
- DMM Scenario 2:
  - 6,221,000 to 8,294,000 cy to off-site disposal facilities in compliance with the off-site rule

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also provided in Common Elements of the Alternatives.

**10.2.8. Alternative H**

DMM Scenario 1:

Capital Costs:	\$8,869,180,000
Periodic Costs:	\$1,284,174,000
Present Value:	\$9,445,540,000

DMM Scenario 2:

Capital Costs:	\$8,948,573,000
Periodic Costs:	\$1,284,174,000
Present Value:	\$9,524,940,000

Construction Duration: 62 years

Alternative H was screened out due to implementability and cost considerations. Given the extensive degree of capping and dredging associated with Alternative H, the volume of material to be handled, and the expected construction duration (62 years), which would include impacts to the community and disruption and potential releases to the environment for that period of time, Alternative H is considered less implementable than the other alternatives. Alternative H also would have a cost approximately 5 times higher than the next closest alternative (Alternative G).

Alternative H uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. The RALs for this alternative are based on the cleanup

levels for the focused COCs. It is the most aggressive of all the alternatives since it would remove the most volume of contaminated material from the Site and would not include/rely on MNR to achieve sediment cleanup levels. Sediment cleanup levels would be achieved at the end of construction. This alternative would support DMM Scenario 1 – off-site disposal and CDF and DMM Scenario 2 – off-site disposal because it would generate enough dredged material to justify constructing a CDF.

Alternative H would have a total constructed area of 2,167 acres of sediment and 30,048 lineal ft of river bank. All contaminated areas would be addressed through dredging and capping. MNR would not be a component of this alternative.

This alternative would include capping and dredging 2,167.2 acres of contaminated sediment. Additionally, 30,048 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

#### *Site Wide*

- Dredging (various depths): 1,631.9 acres - 25,115,000 to 33,487,000 cy of sediment
- Excavating: 158,000 cy of soil
- Capping area: 535.3 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 0 acres
- MNR: 0 acres
- ENR: 0 acres

The design concept for Alternative H is shown on Figure 26 in Appendix I.

Construction Duration: Alternative H would take an estimated 62 years of construction, with no additional time required to complete processing of dredged material (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization, including pre-design investigation
- Years 1 through 60: In-river construction
- Year 61: Demobilization and mitigation

Disposal: The material removed from the Site under Alternative H would be managed in one of two disposal scenarios:

- DMM Scenario 1:
  - 670,000 cy to the onsite CDF
  - 24,445,000 to 32,817,000 cy to off-site disposal facilities in compliance with the off-site rule
- DMM Scenario 2:
  - 25,115,000 to 33,487,000 cy to off-site disposal facilities in compliance with the off-site rule

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. However, ICs for fish consumption and monitoring of fish tissue may only be needed in the short-term given that cleanup levels in sediment would be met at the time of construction. ICs and monitoring in the long-term would still be needed for any areas capped, since that material would remain in place in perpetuity. The key ARARs associated with this alternative are also provided in Common Elements of the Alternatives.

### **10.2.9. Alternative I**

DMM Scenario 1:

Capital Costs:	\$671,966,000
Periodic Costs:	\$421,940,000
Present Value:	\$745,890,000

DMM Scenario 2:

Capital Costs:	\$751,359,000
Periodic Costs:	\$421,940,000
Present Value:	\$811,290,000

Construction Duration: 7 years

Alternative I was developed as a result of the FS evaluation process of Alternatives B through G in the drafting of the FS. Alternative I is a modification of Alternative E, which would allow a more consistent level of risk reduction in all areas of the Site. Alternative I uses the RALs presented in Table 19 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would support DMM Scenario 1 – off-site disposal and CDF and DMM Scenario 2 – off-site disposal. This alternative would generate enough dredged material to justify constructing a CDF.

Alternative I would have a total constructed area of 291 acres of sediment and 19,472 lineal ft of river bank, would allow 1,876 acres of sediment to naturally recover, and would not address 10,577 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 231.2 acres of contaminated sediment and 59.8 acres of ENR. Additionally, 19,472 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

### *Site Wide*

- Dredging: (various depths): 167.1 acres - 1,414,000 to 1,885,000 cy of sediment
- Excavating: 103,000 cy of soil
- Capping area: 64.1 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy of soil
- In-situ treatment: 0 acres
- ENR: 59.8 acres
- MNR: 1,876 acres

The design concept for Alternative I is shown on Figure 27 in Appendix I.

Construction Duration: Alternative I would take an estimated 7 years of construction, with no additional time required to complete processing of dredged material (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization
- Years 1 through 5: In-river construction
- Year 6: Demobilization and mitigation

Disposal: The material removed from the Site under Alternative I would be managed in one of two disposal scenarios:

- DMM Scenario 1:
  - 670,000 cy to the onsite CDF
  - 744,000 to 1,215,000 cy to off-site disposal facilities in compliance with the off-site rule
- DMM Scenario 2:
  - 1,414,000 to 1,885,000 cy to off-site disposal facilities in compliance with the off-site rule

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also provided in Common Elements of the Alternatives.

## 11. SIGNIFICANT CHANGES TO THE SELECTED REMEDY

During the public comment period on the Proposed Plan, EPA received extensive comments from community groups, neighborhood associations, environmental organizations, tribes, and individuals stating that the Preferred Alternative (Alternative I) in the Proposed Plan was not protective enough of human health and the environment and relied too heavily on MNR. There was also significant concern about, and objection to, the use of an on-site CDF for disposal. Additionally, the sponsor of a CDF in Terminal 4 withdrew its support for that project during the public comment period. Public comments also expressed a lack of support for using different RAL contamination concentrations for the same contaminant to trigger capping or dredging in different areas of the Site. Many commenters asked that more flexibility be included in the decision trees and sought more clarity about how the remedy would be implemented after gathering additional data to support design.

Consistent with EPA ROD guidance, EPA as the lead agency, "...has the discretion to make changes to the Preferred Alternative identified in the Proposed Plan based either on new information received from the public or support agency or on information generated by the lead agency itself during the remedial process."<sup>14</sup> Therefore, in response to the new information that EPA received during the public comment period, EPA has chosen Alternative F (Modified) (F Mod) including DMM Scenario 2, as the Selected Remedy. EPA has determined that Alternative F Mod will more closely address the concerns raised through public comment about disposal in an on-site CDF, the degree of contaminant reduction achieved by the Proposed Plan Alternative (Alternative I), the use of different RALs for the same contaminant in different locations of the Site with similar characteristics (shallow, intermediate depths), and the request for more flexibility in implementing the Selected Remedy. This section briefly describes the changes. A full description of the Selected Remedy is provided in Section 14, Selected Remedy, and full evaluation details and information for Alternative F Mod are included in Appendix IV. Responses to public comments are included in Part 3, Responsiveness Summary.

Alternative F Mod, now the Selected Remedy, includes using the RALs from Alternative F for all areas of the Site, including FMD areas, outside of the navigation channel to determine where dredging or capping should occur. Within the navigation channel, Alternative F Mod uses Alternative B RALs and all PTW is excavated or dredged 2-3 feet below the authorized dredge depth as an overdredge allowance/buffer zone. If RALs are not achieved or if PTW is found below the feasible depth of dredging or excavation, as determined by EPA, dredging to accommodate a cap and 2-3-foot overdredge allowance will occur. Disposal of dredged materials will be under DMM Scenario 2, or off-site disposal. A revised decision tree has been developed for the Selected Remedy that provides more clarity in how design data will influence design and construction (Figure 28 in Appendix I). The revised decision tree enables caps to be used in dredge areas if RALs are not achieved or if PTW remains based on area-specific analysis. More

---

<sup>14</sup> See A Guide to Preparing Superfund Proposed Plans, Records of Decision, and other Remedy Selection Decision Documents, July 1999.

detail of these changes is provided in Section 14, Selected Remedy. The Selected Remedy is expected to cost about \$1.05 billion and will achieve the following at the end of construction:

- Remove or contain more of the persistent contaminants from the food chain than Alternative I (3,017,000 cy compared to 1,750,000 cy of sediment) and will achieve greater risk reduction at the end of construction, allowing people (other than women who are or may breastfeed) to safely eat more fish, sooner.
- Reduce, relative to Alternative I, the potential for direct contact with contaminants by users of the river (fishers, divers, swimmers, boaters, homeless population, etc.).
- Reduce risks to the environment, including wildlife and aquatic receptors (both resident and migratory fish, birds, benthic organisms, and threatened and/or endangered species). The HQ at the end of construction is estimated to be below 1 except for BEHP, which is expected to be about 3, close to an acceptable risk level of 1.
- Reduce the contaminant load to the Columbia River and Multnomah Channel by removing or isolating 120 more acres of contaminated surface sediments than Alternative I, which is a 50% increase.
- Increase long-term permanence of the remedy through dredging or capping more of the contamination, which could otherwise pose recontamination potential.

Additional changes to the Selected Remedy are detailed below:

- The Selected Remedy will use consistent RALs to define areas for dredging or capping across the Site outside of the navigation channel, whereas Alternative I used different RALs for various areas of the Site (see Tables 19 and 21 in Appendix II). Using consistent RALs in all areas of the Site outside the navigation channel will eliminate any ambiguity or uncertainty regarding which RALs are applicable and will provide a consistent cleanup approach for all COCs in the river.
- In response to comments on the Proposed Plan, EPA has revised, simplified, and clarified the decision tree (Figure 28 in Appendix I) to show how design data will be incorporated into remedial design decisions. In addition, the decision tree is accompanied by specific design requirements, presented in Section 14.2.9.
- The Selected Remedy will address contamination in the navigation channel in the same way it is described in Alternative B in the FS. This is also the preferred alternative for the navigation channel that EPA identified in the Proposed Plan. This decision for the navigation channel is appropriate because the risk exposures and physical conditions in the channel are different from the rest of the Site. Current data indicate that contaminant concentrations in the navigation channel are lower than in shallow and intermediate areas of the river. In the area where dredging will occur within the navigation channel (RM6Nav SDU), there is little disturbance of the sediments by erosive forces. In addition, the potential for ecological exposure to contaminants in the channel is limited since the depth of the channel is greater than 30 ft and most fish species generally reside and feed

in the near shore areas of the Site. Further, the potential for direct human exposure to the contaminants in the navigation channel is limited due to the depth of the water.

- The Selected Remedy will address all PTW, including PTW present in the navigation channel.
- If NAPL or PTW that is not reliably contained is identified in any of the remediation areas under the Selected Remedy, it will be addressed as specified in Section 14.2. The specific technology to be applied will depend on the area of the river and application of the decision tree (Figure 28 in Appendix I).
- The Selected Remedy changes fish/shellfish tissue cleanup levels to fish/shellfish tissue targets only. EPA proposed tissue PRGs in the Proposed Plan because people consume fish and shellfish tissue; therefore, tissue concentrations are the best and most direct measure of risk to resident fish and shellfish consumers from those COCs. However, fish and shellfish derive their COC concentrations from both sediments and surface water in proportions that at this time can only be approximated and estimates of the degree to which this CERCLA action will reduce fish and shellfish tissue concentrations are highly uncertain. Therefore, EPA decided to identify target fish and shellfish tissue concentrations rather than cleanup levels. These targets will be used to assess remedy implementation, such as, to inform fish advisories and evaluate progress toward achieving RAOs. It's important to note that, for PCBs, the tissue targets are risk-based because there is not enough information to represent background fish tissue concentrations. During design and construction, fish tissue data will be gathered which may enable background fish tissue concentrations to be developed.

## **12. SUMMARY OF COMPARATIVE ANALYSIS OF ALTERNATIVES**

CERCLA § 121(b)(1), 42 U.S.C. § 9621(b)(1), mandates that remedial actions must be protective of human health and the environment, be cost-effective, and use permanent solutions and alternative treatment technologies or resource recovery alternatives to the maximum extent practicable. Section 121(b)(1) also establishes a preference for remedial actions that employ, as a principal element, treatment to permanently and significantly reduce the volume, toxicity, or mobility of the hazardous substances, pollutants, and contaminants at a site. CERCLA § 121(d), 42 U.S.C. § 9621(d), further specifies that a remedial action must require a level or standard of control of the hazardous substances, pollutants, and contaminants, which at least attains ARARs under federal and state laws, unless a waiver can be justified pursuant to CERCLA § 121(d)(4), 42 U.S.C. § 9621(d)(4).

In selecting a remedy, EPA considered the factors set out in CERCLA §121, 42 U.S.C. §9621, by conducting a detailed analysis of the viable remedial response measures pursuant to the NCP, 40 CFR §300.430(e)(9).

In this section, Alternatives A through I, including Alternative F Mod, were evaluated in individual and comparative analysis after alternative screening. Alternative C was not carried forward since it was so similar to Alternative B. Alternative H was also not carried forward since

the cost, duration, and impact of implementing this remedy were extremely high and not proportional to added risk reductions. Supporting details for Alternative F Mod are included in Appendix IV. It is important to note that specific values such as residual risk and surface water results updated in Appendix IV and presented in the ROD are not directly comparable with those found in the FS. This is the result of two revisions. First, the immediate time equals 0 ( $t=0$ ) pollutant removal effectiveness of ENR was assumed to be zero in the FS, but was increased to 97.5% in the ROD. The rationale for this revision is explained in Attachment A in Appendix IV. Second, SWACs were computed differently between the ROD and the FS. In the FS, the SWAC values were based on the 95% UCL of the mean, and the mean was the simple average SWACs of the 27 subareas delineated in the statistical analysis presented in Appendix I of the FS. In the ROD, the SWACs are based on the simple average concentrations of each pixel over the entire Site-wide area.

A detailed quantitative summary for each alternative is presented in Table 22 in Appendix II. A qualitative summary is presented in Table 23 in Appendix II where achievement of the threshold criteria is depicted graphically and relative performance of the balancing criteria is ranked from the least to the best.

The analysis includes an evaluation of each alternative, including attainment of the RAOs, using relevant exposure scales (Site-wide and smaller spatial scales) for receptors covered by each RAO consistent with the assumptions used in the baseline risk assessments. SDUs were developed as a tool to evaluate the expected effectiveness of the alternatives at a number of the most heavily contaminated areas throughout the Site. Fourteen individual regions of the river within the Site were designated as SDUs, generally identified as areas with the highest focused COC concentrations over one river mile segment where multiple contaminants and/or benthic risk were identified. One river mile is consistent with the assumed exposure area of a recreational fisher and corresponds with the home range of various ecological receptors evaluated at the Site. Locations of the SDUs and the predominant contaminants associated with each SDU are shown on Figure 29 in Appendix I and in Table 24 in Appendix II. The effectiveness of each remedial alternative is evaluated in part by comparing each alternative's post-construction SWAC to the cleanup levels for each RAO in the SDUs. This comparison provides an assessment of how the different alternatives reduce sediment contaminant concentrations, which can then be used to assess reductions in direct contact risk and to calculate reductions in contaminant concentrations in fish and shellfish tissue. Risks to people and wildlife from eating contaminated fish and shellfish can then be evaluated for each alternative at the end of construction. Consumption of contaminated fish and shellfish is a significant exposure pathway for people and wildlife; thus, it is important to understand the relative improvements that each alternative achieves at the end of construction.

This section provides the relative performance of each alternative against the nine criteria, noting how each compares to the other alternatives under consideration.

---

**Threshold Criteria** - *The first two criteria are known as "threshold criteria" because they are the minimum requirements that each response measure must meet to be eligible for selection as a remedy.*

---

### **12.1. Overall Protection of Human Health and the Environment**

*Overall protection of human health and the environment addresses whether each alternative provides adequate protection of human health and the environment and describes how risks posed through each exposure pathway are eliminated, reduced, or controlled, through treatment, engineering controls, and/or institutional controls.*

Alternative A would not be protective of human health and the environment and contaminated sediments in the Site would continue to impact surface sediments, surface water, and biota and would pose unacceptable risks to human health and the environment for the foreseeable future. Because no action would be taken, Alternative A would result in minimal reductions in COC concentrations and related residual risks. Natural recovery processes would result in reduction in the COC concentrations over time in some areas of the Site but would be unlikely to achieve all cleanup levels for COCs or meet all RAOs in a reasonable time frame. In areas of the Site with the highest contaminant concentrations, natural recovery would be ineffective in achieving cleanup levels in a reasonable time frame. Because Alternative A is not protective, it is not carried forward in the comparative analysis of the alternatives.

All remaining alternatives are expected to be protective of human health by eliminating, reducing, or controlling risks from direct contact or ingestion of contaminated media and fish/shellfish through dredging, capping, treatment of contaminated groundwater and PTW, ENR, MNR and ICs. The more contaminated sediment removed through dredging would be more permanent, thus more protective. Likewise, the more contamination (sediment and groundwater) that is contained by caps would be more protective than reliance on MNR and ICs; however, perpetual cap maintenance would be required to ensure total protectiveness. Thus, comparatively the most permanent alternatives in decreasing order are: G, F, F Mod, E, I, D, then B. Alternatives that included disposal in a CDF would also depend on perpetual CDF maintenance to ensure total protectiveness while disposal off-site in an engineered landfill would be more permanent.

As described in the NCP, ICs supplement engineering controls, as appropriate, to prevent or limit exposures and should not substitute for active response measures or be the sole remedy unless the active measures are determined not to be practicable. Generally, alternatives with greater long term effectiveness are less likely to rely on ICs to achieve protectiveness. Institutional controls are a necessary supplement when waste is left in place above levels that allow for unlimited use/unlimited exposures, as in the alternatives that were evaluated. As stated before, institutional controls, such as fish advisories or proprietary restrictions, should not substitute for more active response measures that reduce, minimize or eliminate contamination unless such

measures are not practicable. Institutional controls can supplement engineering measures to achieve protectiveness. Fish advisories have been shown to achieve less than 100% compliance, so the less a given alternative relies on fish advisories, the greater likelihood it is to achieve protectiveness. Reliance on fish advisories would be greatest with Alternative B and would decrease through Alternatives D, I, E, F Mod, F, and G. Additionally, Alternatives I, E, F Mod, F, and G, in order with less reliance on MNR, would be expected to be protective of the environment and ecological receptors by eliminating, reducing, or controlling risks from direct contact or ingestion of contaminated media and fish/shellfish through dredging, capping, treatment of contaminated groundwater and PTW, ENR, and MNR. Alternatives B and D may not be protective of the environment because of the increased time frame needed to achieve cleanup levels through MNR and the greater time for exposure to contamination. Additionally, although informational ICs can be used to protect people, these ICs would not provide protection for ecological receptors during this time period.

During the FS, the level of risk reduction at the end of construction was calculated based on the contaminant reductions achieved through capping and dredging areas only and did not include any benefit from areas that received ENR. This produced a conservative assessment of the benefits of each of the alternatives. After receiving public comments and performing additional analysis, the level of risk reduction was also calculated with the best possible outcome of ENR included. Results for both can be found in Table 22 in Appendix II and Table 4.3-1 in Appendix IV, respectively.

A summary of alternative performance relative to interim targets to determine overall protectiveness is presented in Table 22 in Appendix II. In general, alternatives that rely more on capping and dredging result in more risk reduction and are more likely to achieve or get closer to the interim targets than less aggressive actions.

## **12.2. Compliance with Applicable or Relevant and Appropriate Requirements**

*Section 121 (d) of CERCLA and NCP §300.430(f)(1)(ii)(B) require that remedial actions at CERCLA sites at least attain legally applicable or relevant and appropriate federal and state requirements, standards, criteria, and limitations which are collectively referred to as "ARARs," unless such ARARs are waived under CERCLA Section 121(d)(4).*

*Applicable requirements are those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. Only those state standards identified by a state in a timely manner and that are more stringent than Federal requirements may be applicable.*

*Relevant and appropriate requirements are those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that, while not "applicable" to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site address problems or situations sufficiently similar to those encountered at the*

*CERCLA site that their use is well-suited to the particular site. Only those state standards that are identified in a timely manner and are more stringent than Federal requirements may be relevant and appropriate.*

*Compliance with ARARs addresses whether a remedy will meet all of the applicable or relevant and appropriate requirements of other federal and state environmental statutes or provides a basis for invoking a waiver.*

Alternatives B through I, including Alternative F Mod, had common ARARs associated with the construction of the alternative since they all utilize essentially the same remedial technologies with varying degrees of area and scope. All alternatives would attain the action-specific and location-specific ARARs. Alternative B would not achieve chemical-specific numeric human health and aquatic life water quality criteria and drinking water ARARs in a reasonable time frame but would attain the action-specific and location-specific ARARs. Therefore, Alternative B, since it will not achieve human health or aquatic health water quality criteria, may not be protective of human health and the environment.

For all alternatives, the ability to meet surface water quality ARARs for some COCs will be limited to the extent that all sources of surface water contamination can be addressed. It is expected that MNR in conjunction with ICs and source control, including control of upland sources, would be necessary to achieve surface water RAOs.

A complete list of ARARs can be found in Tables 25a-c in Appendix II.

---

***Primary Balancing Criteria*** – *The next five criteria, criteria 3 through 7, are known as "primary balancing criteria". These criteria involve the assessment of factors between response measures so that the best option will be chosen, given site-specific data and conditions.*

---

### **12.3. Long-Term Effectiveness and Permanence**

*Long-term effectiveness and permanence refers to expected residual risk and the ability of a remedy to maintain reliable protection of human health and the environment over time, once clean-up levels have been met. This criterion includes the consideration of residual risk that will remain on-site following remediation and the adequacy and reliability of controls.*

The technologies used in Alternatives B through I, including Alternative F Mod, are the same but vary in degree of use. Alternatives that remove more contamination through dredging provide the most permanence, followed by those that effectively isolate it through engineered caps. Dredged contaminated sediment is permanently removed from the river, and capped sediment is securely segregated from contact with receptors. Off-site treatment and land-based disposal facilities are in operation and have proven to be reliable technologies. Dredging, excavating, capping, in-situ treatment, and thin layer covers are reliable and proven technologies as long as they are designed for the appropriate environmental and anthropogenic conditions.

Since the contamination within the SMAs (SMAs are areas of high contaminant concentration defined by the RAL and increase in size as the RAL number goes down) would be either capped or removed, the overall concentrations of contaminated sediment and soil left in place that could re-suspend into the surface water and move within the Site would be greatest with Alternative B and would decrease with the increasing SMA footprint of each alternative. Thus, as the size of the SMA footprint increases, there would be less reliance on MNR processes to achieve RAOs and less potential for recontamination of capped/dredged areas. The time needed to achieve the RAOs for each alternative is uncertain but would likely occur more quickly in areas of deposition and alternatives with more aggressive cleanup and less reliance on MNR. Alternatives that rely more on MNR will take longer to achieve RAOs.

All alternatives will require O&M activities, and long-term monitoring to ensure, among other things, that: cleanup levels were achieved and maintained; fish tissue concentrations were reduced; and reliability of caps were maintained. O&M activities, long-term monitoring, and five-year reviews would continue in perpetuity. Alternatives with a greater acreage of caps would require more monitoring and maintenance to ensure the contaminated sediment is adequately contained. Since Alternative B has the smallest acreage of caps, it would require the least amount of monitoring and maintenance of caps, whereas Alternative G would require the greatest amount. Alternatives E, F, G, and I also would present the option of an on-Site CDF. Should a CDF be constructed and used as a repository for contaminated sediment from the Site, additional monitoring and maintenance requirements would be needed in perpetuity to ensure the material is reliably contained.

Alternatives that rely more on removal of contamination from the waterway through dredging rely less on institutional controls. The amount of area requiring river and land use restrictions is directly proportional to the acreage capped, which would be the least for Alternative B and the greatest for Alternative G. Land use restrictions have been used at many sediment sites and can be effective as long as they are administered by entities that possess the legal authority, capability, and willingness to implement and monitor the control. However, these restrictions may be difficult to implement in the navigation channel and other areas of this heavily used river. Fish consumption advisories would be required under each alternative until RAOs for fish consumption are achieved.

#### **12.4. Reduction of Toxicity, Mobility, or Volume of Contaminants Through Treatment**

*Reduction of toxicity, mobility, or volume through treatment refers to the anticipated performance of the treatment technologies that may be included as part of a remedy.*

This criterion addresses the statutory preference for selecting remedial actions that employ treatment technologies that permanently and/or significantly reduce the toxicity, mobility, or volume of hazardous substances as their principal element.

All retained alternatives include in-situ and ex-situ treatment technologies. PTW and groundwater contamination is addressed through treatment to varying degrees in all alternatives and, as a result, the preference for treatment as a principal element of the remedial action is achieved to varying degrees for all alternatives. In-situ treatment, as discussed in more detail in

the Selected Remedy section, includes adding organoclay, carbon, or other amendments to caps, which will contain or mitigate migration of contaminants to the water column.

As the construction acreage increases, the reduction in toxicity, mobility, or volume of contaminants within the Site would increase. Reduction in the mobility or volume of contaminants in groundwater entering the river would be through the use of reactive caps where the reactive layer would isolate the contaminants as the groundwater fluxes through the cap. Likewise, reactive caps would be used to reduce the mobility of PTW contained in place. Ex-situ treatment of some sediment and soil removed from the Site would result in additional reduction of toxicity, mobility, and volume of contaminants in sediment and soil.

Since the reduction of toxicity, mobility, or volume would generally increase in direct proportion to the construction acreage, Alternative B would provide the least reduction and Alternative G would provide the most reduction. All PTW at the Site would be addressed through dredging or capping by Alternatives E, F Mod, F, G, and I. Reduction in the mobility of contamination would be through removal and containment in a permitted landfill or CDF or sequestration under in-situ caps; however, there would be no reduction of toxicity or volume through permanent or irreversible treatment.

The need for, and type of, ex-situ treatment of excavated river bank or sediment that meets the definition of listed or characteristic hazardous waste under RCRA or Oregon's hazardous waste and materials regulations would be determined by the action-specific ARARs, such as LDRs, if applicable. Some MGP waste at the Site is also subject to a formal 2004 dispute decision<sup>15</sup> and would require treatment in order to protect workers, ensure the waste is handled appropriately, and that proper equipment decontamination occurs.

### **12.5. Short-Term Effectiveness**

*Short-term effectiveness addresses the period of time needed to implement the remedy and any adverse impacts that may be posed to the community, workers, and the environment during construction and operation of the remedy until cleanup levels are achieved.*

Short-term effectiveness was evaluated on a semi-quantitative basis, taking into account the duration of the construction period for each alternative, the use of BMPs to reduce implementation risk, the risk levels anticipated post-construction, and uncertainty associated with MNR achieving cleanup levels.

During construction, impacts to the community, businesses, workers, and the environment would occur for at least 4 months per year (when threatened and endangered species are not migrating through the area) for the duration of the construction project for every retained alternative. Since Alternative B has the shortest estimated construction duration (4 years), implementation of Alternative B would have the least impact to the community, workers, and the environment. As the construction duration increases with the increasing SMA footprint of each alternative,

---

<sup>15</sup> In the Matter of Portland Harbor Superfund Site Gasco Facility, Portland, Oregon, Administrative Order on Consent for Removal Action, Opalski, December 17, 2004.

impacts would also increase. Alternative G would have the longest construction duration (19 years) and, thus, would have the most impact to the community, workers, and the environment.

Short-term impacts to Site workers would be controlled through use of construction BMPs and health and safety plans. Measures, such as air monitoring on-Site and at the Site boundary, and engineering controls would be implemented to control the potential for exposure. Workers would be required to wear appropriate levels of protection to avoid exposure during excavation and treatment activities. Appropriate precautions and controls would be used to prevent incidental and accidental discharges of toxic materials from entering the water column as a result of in-river work. The application of emissions reduction strategies during implementation can reduce short-term impacts posed to the environment and promote technologies and practices that are sustainable according to the EPA Region 10 Clean and Green Policy and the Superfund Green Remediation Strategy (EPA 2010). Elevated fish tissue concentrations from construction activities would also be dependent on the construction duration and would be shortest for Alternative B and longest for Alternative G. Fish consumption advisories would be required under CERCLA for each alternative but relaxed with progress towards achieving fish consumption targets.

Post-construction, environmental impacts would continue until RAOs are achieved. The time needed for MNR to achieve the RAOs for each alternative is uncertain but would likely occur more quickly as a result of alternatives with larger remedial footprints. Alternative B leaves the most contaminated sediment in-river. It relies more on MNR to achieve cleanup levels and it is unlikely that RAOs could be achieved. As the footprint of capping and dredging increases in each alternative, MNR is relied on less to achieve RAOs. Additionally, the less the alternative relies on MNR, the more certainty there is that cleanup levels will be achieved. Alternative G would achieve all environmental RAOs, so there would be no post-construction impacts to the environment. Human health impacts would include elevated contaminant concentrations in fish and shellfish until RAOs are achieved. Fish consumption advisories would be implemented to control human exposure during this time frame.

Each alternative was evaluated to compare the estimated risks remaining at the end of cleanup construction, as well as when cleanup levels are achieved. The risk remaining once the cleanup level is achieved is called residual risk. Table 22 in Appendix II provides the calculated risks at the end of construction for each alternative. Alternatives with smaller cap/dredge footprints have higher risks post construction to human health and the environment, address less groundwater contamination, and include fewer contaminated river banks. Alternatives that have smaller cap/dredge footprints and rely more on MNR have more uncertainty that cleanup levels would be met.

Consuming contaminated fish poses the greatest risk to people at the Site. The background cancer risk at the Site is  $1 \times 10^{-6}$ . At the end of construction, Alternative F Mod has a residual cancer risk for consuming fish/shellfish of  $1.5 \times 10^{-4}$  and non-cancer HI risk of 15 for all populations except women who are or may breastfeed. The residual cancer risk ranges from  $8.9 \times 10^{-5}$  (Alternative G) to  $2.3 \times 10^{-4}$  (Alternative B) for all except the most sensitive populations. The residual noncancer risk ranges from 9 (Alternative G) to 25 (Alternative B) for

all populations except women who are or may breastfeed. Alternative F has residual cancer risk of  $1.2 \times 10^{-4}$  and noncancer risk of 13.

Risks to benthic communities from exposure to contaminated sediment are 48% addressed with Alternative B, 64% with Alternative D, 73% with Alternative E, 87% with Alternative F, 72% with Alternative F Mod, 93% with Alternative G, and 64% with Alternative I. Additionally, only Alternatives F, F Mod, and G address all risks to wildlife from consuming prey contaminated with PCBs.

In the river bank areas, the magnitude of residual risk is uncertain because it is likely that not all contaminated river bank material would be addressed by any CERCLA alternative but could be addressed by the state source control work. Post-construction, the area of contaminated river bank would decrease with the increasing SMA footprint for each alternative in the following order: Alternative B, D, E, I, F Mod and F (same amount addressed), then G.

## **12.6. Implementability**

*Implementability addresses the technical and administrative feasibility of a remedy from design through construction and operation. Factors such as availability of services and materials, administrative feasibility, and coordination with other governmental entities are also considered.*

The construction activities required for the implementation of all retained alternatives would be technically feasible and have been implemented at many Superfund sites around the country. Materials, services, and equipment necessary for construction are readily commercially available. Disposal facilities are also readily available and have adequate capacity for the volumes of material to be removed.

In general, the potential for technical problems and schedule delays increases in direct proportion to the duration and amount of active remediation. As the construction acreage of the alternative increases, the construction period, required administrative coordination, and the potential for technical problems leading to schedule delays would increase. The implementation logistics also would increase in difficulty as more construction acreage is added in each alternative.

Conversely, alternatives with the smallest construction acreage would have a greater potential to need additional actions if monitoring data indicate inadequate performance in achieving all cleanup objectives. The risk of monitoring failing to detect a release of COCs to the environment in areas where waste has been left in place (caps, ENR, or MNR areas) increases as the footprint of capped areas increases.

Installation of an on-site treatment, storage, and transfer facility would require cooperation from the landowner and coordination with local authorities for the construction of utilities within existing rights-of-way.

## **12.7. Cost**

*Costs include estimated capital, long-term O&M, and present value costs.*

The cost of each alternative increases as the degree of construction increases. The estimated present value costs for the alternatives (under DMM Scenario 2) range from \$451 million for

Alternative B to \$1.77 billion for Alternative G. Cost summaries can be found in Table 26 in Appendix II.

---

***Modifying Criteria** – The final criteria 8 and 9 are known as "modifying criteria." Community and support agency acceptance are factors that are assessed by reviewing comments received during the public comment period.*

---

## **12.8. State and Tribal Acceptance**

*Indicates whether based on its review of the RI/FS reports and the Proposed Plan, the state and affected tribes support, oppose, and/or have identified any reservations with the selected response measure.*

DEQ, as the support agency, was actively involved in developing the FS and the remedial alternatives. The State of Oregon's concurrence letter is included as Appendix V.

The State of Oregon also provided comments to EPA on the Preferred Alternative. In addition to other issues, the state highlighted their concern that the remedy did not include enough flexibility for remedy implementation. They asked for more clarity about the river bank cleanup, that a broader area be cleaned up for benthic risks, and that EPA consider changes to the FS cost estimates.

EPA has extensively engaged with the six federally recognized tribes before the Site was listed on the NPL and throughout the development of the RI/FS.

The Columbia River is an important natural resource for the tribes and EPA has received comments from the tribes requesting that the effects of Portland Harbor contamination to the Columbia River be considered when evaluating cleanup alternatives at the Site. The primary objective of the ROD is to address the contaminated sediment in Portland Harbor, significantly reducing sediment concentrations and potential human health and ecological risks at the Site. Although reducing loading to the Columbia River is not a specific objective of the Selected Remedy, it is an expected outcome of achieving the RAOs presented in Section 9 of the ROD. During construction, monitoring will be conducted to determine, in part, whether additional BMPs are needed to minimize downstream transport of contamination.

Additionally, consultation was offered to all six tribes prior to and during the public comment period. In January and February 2016, consultations were held with the Confederated Tribes of the Umatilla, Warm Springs, Grand Ronde, Siletz, as well as the Nez Perce Tribe and the Confederated Tribes and Bands of the Yakama Nation. Consultation with the Warm Springs was cancelled by the Tribe due to scheduling conflicts. In July, another round of consultations was held with the Confederated Tribes of the Grand Ronde, Umatilla, and the Yakama Nation. The Yakama Nation consultation was held with the EPA Administrator in Washington D.C. In consultation and in written comments, the tribes all expressed concerns with the Proposed Plan Preferred Alternative. They expressed concerns about the extent that the Preferred Alternative

relied on MNR and expressed uncertainty that the cleanup would be protective of Tribal Treaty rights. The tribes stated that they did not believe the Proposed Plan Preferred Alternative was sufficient to address contamination at the Site and they specifically asked that EPA consider impacts to fish and plants of cultural and historical significance to the tribes, including the pacific lamprey.

## **12.9. Community Acceptance**

*Summarizes the public's general response to the response measures described in the Proposed Plan and the RI/FS reports. This assessment includes determining which of the response measures the community supports, opposes, and/or has reservations about.*

EPA has actively engaged with the community on a regular basis since the NPL listing of the Site in December of 2000. These efforts included producing and disseminating quality information such as community information cards, fact sheets, and videos; establishing information repositories at the Multnomah County Central Library, the St. Johns Library, and the Kenton Library where the public can review documents associated with the Site; maintaining current information on EPA's Portland Harbor website; providing valuable information via the EPA Portland Harbor listserv; sustaining strong partnerships with DEQ, OHA, and the City of Portland to maximize community outreach efforts; attending and presenting at public forums and meetings; engaging with many different groups, including groups that represent or are concerned about communities with environmental justice concerns; and organizing multiple community information sessions during January, February, and March of 2016. During the public comment period for the Proposed Plan, EPA went well beyond the typical rollout of a proposed plan by holding four public meetings in June and July of 2016 (June 24, June 29, July 11, and July 20), as detailed in Section 4 (Community Participation). A detailed list of specific community involvement activities is available in EPA's current Portland Harbor Community Involvement Plan (accessible on EPA's website).

Through the public comment period, EPA received letters from more than 5,300 different commenters. These comment letters were analyzed to extract specific comments and categorized by topic.

Of the general public comments received, approximately 88% expressed concern that the Preferred Alternative (Alternative I) did not go far enough to address contamination at the Site. Commenters were concerned that more than 85% of the area of the Site would receive no active remedy, but would rely on MNR to achieve cleanup goals. Commenters asked that EPA take more aggressive action to cleanup the Site and rely less on natural recovery. Additionally, there was substantial disapproval of building a CDF at the Site for waste disposal. Some public comments raised concerns about impacts on local businesses and jobs due to the cost of the cleanup and disruption of navigation. Public comments from businesses and commenters identified as PRPs were generally not in favor of the Preferred Alternative due to the extent of cleanup and cost and the perspective that MNR should be relied on more. PRP commenters in general did not agree that there is as much risk at the Site as the risk assessments determined. Such commenters also expressed a lack of support for using different RAL contamination

concentrations for the same contaminant to trigger capping or dredging. Many such commenters asked that more flexibility be included in the decision trees and sought more clarity about how the remedy would be implemented after gathering additional data to support design. Numerous comments were also received regarding environmental justice and public participation concerns. EPA has addressed these comments in Part 3, the Responsiveness Summary.

#### **12.10. Summary of Comparative Analysis**

A summary of the comparative analysis of the retained alternatives is presented below; the benefits and limitations of the alternatives relative to one another are described. Table 22 in Appendix II provides a summary of the comparative analysis of the alternatives and Table 23 in Appendix II is a simple graphic of comparative ratings of the alternatives.

All alternatives would rely equally on the adequacy of DEQ's source control to achieve cleanup levels and RAOs and to prevent recontamination of the Site. Addressing river banks would also help prevent recontamination of the Site after in-river response actions are completed.

Alternatives E, F Mod, F, G, and I would meet the threshold criteria of Overall Protection of Human Health and the Environment and Compliance with ARARs. Alternative D may meet the threshold criteria but there is more uncertainty with this alternative and its ability to achieve ARARs. Alternative A is not protective and Alternative B would not achieve all chemical-specific ARARs and may also not be protective. Therefore, since Alternatives A and B would not meet the threshold criteria, they will not be discussed further.

Alternatives E, F Mod, F, G, and I would address all PTW at the Site through capping or dredging and would achieve the preference for treatment when applicable. Alternative D would not address all PTW at the Site.

Alternatives F Mod, F, and G would achieve the greatest risk reduction and their estimated cancer risks at the end of construction are approximately one-quarter to half of those for Alternatives E and I. All remaining alternatives would control the major sources of sediment contamination by sequestering higher contaminant concentrations under engineered caps or by removing the material and containing it in a disposal facility, which would be maintained in perpetuity. The alternatives that have larger capping or dredging footprints provide more certainty that cleanup levels will be achieved and that no additional actions will be required but do result in more impacts to the community and workers implementing the remedy. Alternatives E and I, with a construction duration of 4 months per year (construction fish "windows") for 7 years, would have fewer impacts from construction to the community, workers implementing the remedy, and the environment compared to Alternative F (13 years), Alternative F Mod (13 years), and Alternative G (19 years). Although Alternative G has the largest cleanup footprint, it also has the longest construction time period and thus, increased impacts to the community and workers, and it is not certain that cleanup levels would be achieved more quickly with this alternative than Alternatives F or F Mod. Alternatives F Mod, F, and G would have greater impacts to the environment than Alternatives E and I due to the increased construction footprints and time needed for construction (2 to 3 times longer to implement). Alternatives F, F Mod, and G achieve most of the interim targets at the end of construction compared to other alternatives.

Alternatives F, F Mod, and G are more reliable in achieving cleanup levels and RAOs in a reasonable time frame because they rely less on natural processes.

Estimating the number of fish meals that can be safely eaten at the end of construction is not a precise calculation but rather is a prediction that has some degree of uncertainty. However, such calculations are useful to allow comparison of the outcomes of the different alternatives. Fish advisories will be required for all alternatives and will be needed under CERCLA until RAOs for fish consumption are met. For Alternative D, at the end of construction in 6 years, adults could safely consume about 11 fish meals per year. For Alternative E and after 7 years of construction, approximately 13 fish meals per year would be safe. Alternative F would allow 19 fish meals per year after 13 years of construction, Alternative F Mod allows 16 fish meals per year, and Alternative G would allow 26 fish meals per year after 19 years of construction. Alternative I, after 7 years of construction, would allow 13 fish meals per year. It is expected that RAOs for fish consumption would be reached more quickly with the more aggressive alternatives although the time for construction does need to be included in the total time to meet these goals. Since concentrations of contamination post-construction left to MNR would be greater for Alternative D, it is expected that a longer period of recovery would be necessary to meet cleanup levels and RAOs and thus fish advisories would be necessary for a longer period of time. After construction of Alternative F Mod, the number of fish meals per year that are safe to eat is almost 20% more than that of Alternatives E and I. Although Alternatives F and F Mod require an additional 6 years of construction than Alternatives E and I, it is expected that the aggressive actions of Alternatives F and F Mod would achieve fish consumption RAOs more quickly than Alternatives E and I. Alternative G provides about 40% and 37%, respectively, more fish meals per year than Alternatives F Mod and F, but would also require 6 more years of cleanup construction.

Fish advisories would be further informed by fish sampling conducted during and after construction. Alternatives that remove COCs from the system provide greater assurance that cleanup levels will be achieved and that more fish can be safely consumed. After cleanup levels are achieved at the Site, OHA may still impose an advisory based on broader watershed risks. Because the COC contaminants can pose risks even when the concentrations in the environment appear to be quite low, it is critically important to remove these persistent pollutants from the environment so they are no longer available to receptors and are removed from the food chain.

Engineered caps on river banks and sediment would be effective in limiting the long-term exposure to COCs in the Site sediment and soil, provided they are properly designed and the integrity of the caps is maintained. Therefore, monitoring and maintenance of the caps would be required in perpetuity. Caps also require river use restrictions and, where appropriate, armoring to prevent cap erosion, which may require mitigation. Steep slope angles for certain river bank caps may also require mitigation. Alternatives E and I have approximately the same RNA capped area (81 acres). Alternative D has less capped area (56 acres) but does not reliably contain all PTW remaining in the river. Compared to Alternatives E and I, Alternative F and F Mod have almost twice the capped area (150 acres), and Alternative G has more than 2.5 times the capped area (231 acres). As the area to be capped increases, more long-term monitoring, maintenance, and river use restrictions would be required.

All the alternatives would achieve reduction of toxicity, mobility, or volume through treatment by using in-situ and ex-situ treatment technologies that have been demonstrated to be effective at Superfund sites around the country. In all alternatives, it is estimated that approximately 191,000 cy of removed sediment and soil would be treated ex-situ at the off-Site disposal facility using low temperature thermal desorption or cement solidification/ stabilization. In-situ treatment would be applied to areas where PTW that cannot be reliably contained or NAPL is left in place or where residual groundwater plumes may discharge to the river. In-situ treatment would be applied to areas of the Site through the addition of reactive components to caps and residual layers, with increasing acres as follows: Alternatives D (108 acres), Alternative E (109 acres), Alternative I (113 acres), Alternative F Mod (133 acres), Alternative F (145 acres), and Alternative G (184 acres). Alternatives E, F Mod, F, G, and I would ensure that the preference for treatment is achieved for all PTW.

The majority of the currently identified groundwater plumes are expected to be controlled by DEQ's upland source control actions and the remedial alternatives will only need to address the portion of the plumes that extend into the river or that continue to discharge contaminants to the river. Since the extent that these plumes impact the biologically-active zone in sediment (pore water) or surface water is not currently known, these areas will need to be refined during remedial design and, at that point, it will be determined which residual groundwater plumes will need to be addressed in the river through engineered caps. The alternatives would address an increasing percentage of the contaminated groundwater area as currently delineated in the following order: Alternative D (23%), Alternative E (32%), Alternative I (33%), Alternative F Mod (39%), Alternative F (46%), and Alternative G (62%).

Informational ICs can be used to protect people but these ICs would not provide protection for ecological receptors. Therefore, it is ideal to address, to the maximum extent possible, all ecological risks at construction completion. While none of the alternatives would address all ecological risks, Alternative G would address the most ecological risks at the completion of construction, although it would impact their habitat for the longest period of time during construction (19 years) and would take the longest time for benthic populations to recover due to the large area of habitat impacted (776 acres). Alternatives D, E, F, F Mod, G, and I would address more than 50% of the benthic risk area, which would be sufficient to ensure risks would not occur to the benthic population as a whole. Although the benthic community will be disrupted by construction activities, past experience has shown rapid recolonization of disturbed areas after construction is completed. Alternative F would disrupt 533 acres, Alternative F Mod 394 acres, Alternative E 329 acres, Alternative I 291 acres, and Alternative D 267 acres.

Removing contaminated sediment and river bank soil from the river has long-term benefits for the Site, but there are also impacts to the environment and community associated with transporting the removed material to a disposal facility. By removing approximately 4,585,000 cy and 7,397,000 cy of contaminated material from the system, Alternatives F and G would present the greatest impact to the community but they would also achieve higher post-construction risk reduction compared with current risks of contaminated sediment. Alternative F Mod removes approximately 3,017,000 cy of contaminated sediment from the system and

achieves similar risk reduction to Alternative F. Alternatives E and I would have similar removed material volumes (approximately 2,024,000 cy and 1,752,000 cy, respectively) and only achieves half the cancer risk reduction as Alternatives F and F Mod. Implementing Alternative G would impose the greatest impacts to the environment and community and would have much greater costs (2 times more than Alternatives E and I). Depending on the form of transportation used for the removed material, these impacts would include increased barge traffic on the river, which would impact commercial and recreational use of the river, increased traffic on the roads in the community if trucking is used, and increased traffic on the rail lines if rail is used. There would also be increased environmental impacts, such as potential spills, benthic disruption, and sediment disturbance from wake waves and prop wash, associated with transporting such large volumes of material.

Treatment and disposal of approximately 206,300 cy of contaminated sediment and soil are assumed to be at a Subtitle C landfill for all alternatives and DMM scenarios. This material would be barged to an off-Site trans-loading facility and trucked to the landfill because it would not meet the criteria for disposal in a Subtitle D landfill or a CDF.

Alternatives F, F Mod, and G contaminant concentrations would be within 3 to 4 times the surface water cleanup levels; all other alternatives are higher. It is expected that MNR in conjunction with ICs and source control, including control of upriver sources, would be necessary to achieve surface water RAOs. The ability to meet surface water quality cleanup levels for ARARs for these COCs will be limited to the extent that all sources of surface water contamination can be addressed.

Natural recovery of contaminated sediment is expected to occur as cleaner upriver sediments deposit on surface sediment in the Site during low-flow periods and mix and disperse downstream during higher flow periods. The surface sediment concentrations need to be low enough and upland and in-river sources of contamination need to be reduced enough such that these natural processes would be able to reduce contaminant concentrations to the cleanup levels in a reasonable time frame. As the footprint for MNR decreases, the area of disturbance of the aquatic environment due to construction would increase, the longer these disturbances would occur, and alternative costs increase. Alternatives D, E, and I would have about the same MNR footprint (87%, 84%, and 86% of the Site, respectively) while Alternatives F, F Mod, and G have MNR footprints of 75%, 81%, and 64%, respectively, or approximately 10%, 5%, and 20% smaller MNR footprints, respectively. The Site-wide post-construction surface sediment PCB concentrations (the contaminant that poses the greatest risk) are reduced by 62% for Alternative D, 67% for Alternatives E and I, 77% for Alternative F, 72% for Alternative F Mod, and 83% with Alternative G relative to baseline (pre-cleanup) concentrations.

MNR is not currently considered to be effective within Swan Island Lagoon because water circulation is limited, and, as a result, it may not receive sufficient cleaner sediment from upstream to allow natural recovery to occur in areas with lower contaminant concentrations. For this reason, ENR, which involves placing a sand layer on the contaminated sediment, would be used to further reduce contaminant concentrations in these areas. For this process to be effective, a sufficient amount of capping/dredging in areas with higher contaminant concentrations would

be needed in Swan Island Lagoon. As the capping and dredging areas for each alternative increase, the certainty that ENR would achieve cleanup levels also increases. Alternative D has the largest ENR footprint (87 acres or 74% of the area within Swan Island Lagoon); Alternatives E and I have the same ENR footprint (59.8 acres or 51%) while Alternatives F, F Mod, and G have the smallest ENR footprints (28.2 acres [24%], 28.2 acres [24%], and 19.5 acres [16%], respectively).

The cost of the alternatives increases as the area requiring active cleanup increases. Therefore, the present value costs of the alternatives range from lowest to highest: Alternatives D (\$653,700,000), I (\$811,290,000), E (\$869,530,000), F Mod (\$1,054,200,000), F (\$1,371,170,000), and G (\$1,777,320,000).

### **13. PRINCIPAL THREAT WASTES**

The NCP establishes an expectation that EPA will use treatment to address the principal threats posed by a site wherever practicable (NCP §300.430(a)(1)(iii)(A)). PTWs are source materials that include or contain hazardous substances, pollutants or contaminants that act as a reservoir of contaminants that can migrate to groundwater, surface water, or air, or act as a source for direct exposure. Contaminated groundwater generally is not considered to be a source material; however, NAPLs in groundwater may be viewed as source material. Principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. Low-level threat wastes are those wastes that generally can be reliably contained and present only a low risk in the event of exposure. The identification of principal and low level threats is made on a site-specific basis to help streamline and focus waste management options by categorizing the suitability of the waste for treatment or containment.

PTW was identified at the Site based on one or more of the following considerations: a  $10^{-3}$  (1 in 1,000) cancer risk from concentrations in sediment, existence of source material such as NAPL within the sediment bed, or an evaluation of mobility of contaminants in the sediment.

Alternatives that considered treatment of PTW were developed in the FS and described in Section 10.2. Each alternative uses treatment (in-situ and/or ex-situ) to address PTW; however, not all of the alternatives address all of the PTW with treatment. Alternatives E, F Mod, F, G, and I would address all PTW, while Alternative D would address 57%.

PTW is also described in Sections 6.5.1 and 10.1.1 of the ROD.

### **14. SELECTED REMEDY**

Based on consideration of the requirements of CERCLA, the detailed analysis of the remedial alternatives, and public comments, EPA has selected Alternative F with Modifications (Alternative F Modified or F Mod) as the Selected Remedy with offsite disposal of all excavated waste materials. Alternative F Mod, now the Selected Remedy, includes using the RALs from Alternative F for all areas of the Site, including the FMD areas, outside of the navigation channel to determine where dredging or capping should occur. Within the navigation channel, Alternative F Mod uses Alternative B RALs and all PTW is excavated or dredged 2 to 3 feet below the

authorized dredge depth as an overdredge allowance/buffer zone. If RALs are not achieved or if PTW is found below the feasible depth of dredging or excavation, as determined by EPA, dredging to accommodate a cap and 2-3-foot overdredge allowance will occur. If RALs are not achieved or if PTW remains after dredging occurs in areas outside the navigation channel, a cap will be constructed according to approved designs to support river uses in those locations. Disposal of dredged materials will be under DMM Scenario 2, or off-site disposal. A revised decision tree has been developed for the Selected Remedy, which provides more information about how design data will influence design and construction and future maintenance dredging areas (Figure 28 in Appendix I). RALs for the Selected Remedy are shown in Table 21 in Appendix II and cleanup levels and fish tissue targets for the Selected Remedy are included in Table 17 in Appendix II. This section provides EPA's rationale for the Selected Remedy and a description of its anticipated scope, how the remedy will be implemented, and its expected outcomes. Details about the number of acres addressed through cleanup, volume of contaminated material dredged, and other information for Alternative F Mod are included in Appendix IV.

#### **14.1. Summary of Rationale for the Selected Remedy**

The Selected Remedy is protective of human health and the environment, complies with ARARs, and provides the best balance of tradeoffs among the balancing criteria, including addressing many of the Tribal community's concerns as well as community concerns raised through public comments. It reduces risks within a reasonable time frame, is practicable, provides for long-term reliability of the remedy, and minimizes reliance on institutional controls. It will achieve substantial risk reduction by dredging and capping areas with the most contaminated sediments, reduce remaining risks to the extent practicable through ENR and MNR, and manage remaining risks to human health through institutional controls. The Selected Remedy also relies less on MNR than most other alternatives, which will result in achieving cleanup levels more quickly.

The Selected Remedy is more permanent in the long term because it addresses more contamination in all areas of the river outside the navigation channel and relies less on MNR than Alternatives D, E, and I. The Selected Remedy presents greater short-term impacts to the community and habitat than Alternatives D, E, and I but achieves higher post-construction risk reduction for both humans and ecological receptors compared with current risks from contaminated media. The Selected Remedy ensures that the preference for treatment is achieved for all PTW and significantly protects the river from impacts from contaminated groundwater plumes discharging into the Site. The Selected Remedy addresses less contamination in the navigation channel than Alternative F from the FS and there is less dredging/excavation (approximately 1,568,000 fewer cy) compared to Alternative F and with less impacts to the river and local community. Although Alternative G relies the least on MNR, the additional cost for this alternative is not commensurate with the additional risk reduction and increased certainty.

The Selected Remedy addresses 79% of RAO 2 (fish/shellfish consumption) risk with active and more permanent cleanup components in relation to its cost. Construction time for the Selected Remedy is currently estimated to be 13 years, consistent with Alternative F, but may likely require less time since less material in the navigation channel will be dredged as compared to Alternative F. Disposal of all excavated or dredged material will occur off-site and not in an on-

site CDF. Reliance on existing, permitted facilities for disposal increases the implementability of the remedy and also may reduce estimated construction time.

After cleanup construction, the Selected Remedy provides full protection for recreational users of the river as well as all wildlife that live and consume prey within the Site. After cleanup construction, adults (other than women who are or may breastfeed) can safely consume approximately 16 resident fish per year, which is much more than is currently advised. The Selected Remedy uses consistent RALs to define the areas for dredging and capping across the Site, removing uncertainty over the application of different RALs for the same contaminants at different areas of the Site. The modifications to the RALs for the navigation channel are appropriate because the risk exposures and physical conditions in the channel are different from the rest of the Site. Exposure to contaminants in the channel is limited since the depth of the channel is greater than 30 ft and based on information gathered during the RI, the understanding is that most of the fish species feed in the near-shore areas of the Site.

#### **14.2. Description of the Selected Remedy**

The Selected Remedy addresses all areas where contaminant concentrations exceed the cleanup levels through a combination of dredging, capping, ENR, MNR, and ICs. Cleanup levels were selected after evaluating concentrations protective of human health or the environment from the risk assessment, ARARs, and background values. For each contaminant and in all media, the lowest number was selected unless the background value (where we have them) was higher, in which case the background value was selected. Table 17 in Appendix II provides the cleanup levels and tissue targets as well as the basis for the number. In general, sediment cleanup levels are based on levels protective of fish and shellfish consumption, which are also protective for benthic risks. The invertebrate community living in the sediments provides important food for fish and other species in the Site. The biologically active zone of the Site that supports benthic communities is in the “shallow” sediment (less than 38 cm deep) and is generally 10 to 20 cm deep, based on sediment profiling imaging data. Therefore, surface water and groundwater cleanup levels are primarily based on ARARs that are protective of designated uses of the river and groundwater. In addition, both groundwater and surface water are potential drinking water resources and discharges of contaminants to the river from groundwater and pore water represent one continuous pathway. Therefore, application of MCLs and RSLs (if a contaminant has no MCL) is relevant and appropriate as cleanup levels. Addressing areas with contaminated groundwater by dredging and capping will also reduce loading to surface water and reduce exposure to benthic and invertebrate organisms living in sediment. The cleanup levels for the Site are expected to reduce unacceptable risk within the river by setting standards for sediment, biota, surface water, groundwater, and river banks. Remediation of the sediment will reduce loading and resuspension of contamination to surface water, which collectively will reduce fish and shellfish exposure to the contamination.

SMA for the Selected Remedy are shown in Figure 30 in Appendix I. Areas to be capped or dredged will be defined by RALs for the Selected Remedy (Table 21 in Appendix II). RALs are contaminant-specific sediment concentrations of focused COCs used to define areas for more active cleanup and will reduce contaminant concentrations and risks more effectively than ENR

or MNR from current Site-wide average concentrations. Technology assignments and the approximate areas that will be remediated through dredging, capping, ENR, and areas where COC concentrations will be reduced through MNR are discussed below and shown on Figures 31a-e in Appendix I. The Selected Remedy will include a total constructed area of 394 acres of sediment and 23,305 lineal feet of river bank, and will allow 1,774 acres of sediment to naturally recover. Supporting analysis and information for the Selected Remedy are included in Appendix IV. River bank areas not remediated concurrent with adjacent sediment dredging/capping will remain under state purview for assessment and potential future action as needed to prevent recontamination of the remedy at this time. DEQ may also undertake action at some river banks that are the subject of this ROD to expedite source control of contaminated upland areas, as necessary. Those actions will be consistent with the Selected Remedy and meet CERCLA requirements.

The Selected Remedy includes 365.4 acres of capping and dredging contaminated sediment and 28.2 acres of ENR. Of that, approximately 215.2 acres of sediment will be dredged to varying depths. Additionally, 23,305 lineal feet of river bank are assumed to be excavated and covered with either an augmented reactive cap or an engineered cap using beach mix or vegetation after excavating approximately 123,000 cy of contaminated material from river banks. The dredged material removed from the Site will be managed under DMM scenario 2, with approximately 3,017,000 cy of contaminated sediment and 123,000 cy of soil sent to off-site disposal facilities. Material testing will be used to determine the appropriate disposal facility, Subtitle D or C. Ex-situ treatment is assumed for approximately 191,500 cy of sediment and river bank soil prior to disposal and is based on complying with federal and state regulations and the 2004 dispute decision on MGP waste. The need for, and extent of, ex-situ treatment will be based on the off-site disposal requirements and material testing during design and construction. It is assumed that all other dredged material will not require treatment prior to disposal. All material quantities that will be addressed by the Selected Remedy are summarized in Table 27 in Appendix II.

Under the Selected Remedy, 60 acres of compensatory mitigation is estimated, based on armored capping acreage, which includes 2 acres of armored caps to be placed on river banks and 58 acres of armored caps to be placed on sediment in the shallow area, defined as above -15 feet CRD per the NMFS' definition of shallow water. Where the remedial action adversely impacts habitat, the cap will be designed to minimize the impacts and restore the surface for habitat function, but if loss of habitat occurs, compensatory mitigation will be undertaken. The details of any necessary compensatory mitigation will be developed during remedial design. Compensatory mitigation likely will entail the restoration, establishment, enhancement, and/or preservation of wetlands, streams, or other aquatic resources conducted specifically for the purpose of offsetting authorized impacts on-Site wherever possible. If mitigation banks, as defined in the 404(b)(1) Guidelines, are permitted and approved by the USACE and State of Oregon within the Site or appropriate service area, buying credits in such a bank may be acceptable if approved by EPA.

The various river areas and their remedy components are discussed in detail below. The final technology assignment will be identified in the remedial design, after collection of additional

sampling data in all areas and segments of the river. The technology assignment will be identified as indicated in the decision tree in Figure 28 in Appendix I.

The Selected Remedy for the in-river portion of the Portland Harbor Site covers a large area and comments raised during the public comment period sought clarity about how the remedy would be implemented using the decision trees and how it would be phased for purposes of remedial design and/or construction. Further information is presented below on both of those issues.

#### *Post-ROD Data Gathering and Other Information Verification*

For purposes of the FS, several assumptions were made about what the Selected Remedy would look like in the river after applying the decision tree based on existing data. Post-ROD sampling will be conducted to support remedial design and to refine the CSM. This updated information will be used for design/construction. Post-ROD sampling will include, in addition to other relevant data, surface and subsurface sediment contaminant concentrations, surface water, sediment pore water and groundwater data, bathymetry, flood-rise modeling, fish/shellfish tissue, and NAPL delineation.

In addition, reasonably anticipated future navigation and land use information and other data will be collected at a much greater level of detail than information collected as part of the RI to support the Remedial Design. As part of the FS, observed current uses were assumed to continue in the river. During the public comment period, some parties identified that the potential future use(s) of a part of the river may be other than current uses or EPA's assumptions. To ensure that the correct reasonably anticipated future uses are used for the remedial design, these assumptions will be verified and will be altered, as appropriate. For example, eliminating the need for a more expensive dredge and armored cap remedy if a significant area will no longer to be used for marine terminal purposes.

This updated information will inform the implementation of the Selected Remedy decision tree. When applying the decision tree logic with newly gathered information, the design and constructed remedy will reflect the newer information. For example, areas exceeding the RALs will be identified for capping and dredging based on new data, which is likely to create different SMA footprints from what was assumed in the FS. In areas to be dredged or capped, a technology assignment process (FS Figures 3.8-1-b and 3.8.1-c) identifies either capping or dredging for each area. After identifying appropriate cap or dredge technologies through this process, further modifications may be necessary during design to ensure the final constructed remedy is appropriate for actual Site conditions.

It is EPA's expectation that the majority of the currently identified groundwater plumes will be addressed by DEQ's upland source control actions and the Selected Remedy will only need to address the portion of the plumes that extend into the river or that continue to discharge contaminants to the river above cleanup levels. Since the full extent that these plumes impact the biologically-active zone in sediment (pore water) or surface water is not currently known, these areas will need to be refined during remedial design and, at that point, it will be determined which residual groundwater plumes will need to be addressed in the river with engineered caps. It is further expected that design of in-river remedies (such as cap design) will consider how

effectively the upland source control measures are addressing the groundwater contaminant loading to the river.

For purposes of the FS, disposal locations and requirements were assumed and cost estimates were calculated based on those assumptions. If during design more proximate or cost-effective disposal facilities emerge, EPA would support use of these options to reduce the cost and environmental impact of the cleanup.

#### *Construction Time Frame*

The Selected Remedy components are shown on Figures 31a-e in Appendix I, including technology assignments. The in-river construction duration for this alternative is estimated to be 13 years. The following construction schedule time frames are estimated:

- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization
- Years 1 through 11: Construct alternative
- Year 12: Demobilization

The remedy may change somewhat as a result of the remedial design and construction processes. Changes to the Selected Remedy described in this ROD will be documented using a technical memorandum in the Administrative Record, an Explanation of Significant Differences (ESD), or ROD amendment.

#### **14.2.1. Navigation Channel**

The Selected Remedy in the federally-authorized navigation channel includes dredging to avoid constructing a remedy (cap or residual layer) within the authorized dredge depth. Contaminated sediment will be dredged to the depth of the Alternative B RAL concentrations or PTW concentrations shown in Table 21 in Appendix II, whichever is lower. Where RALs are achieved through dredging, placement of a residual layer will occur as soon as is practicable following dredging within the prism and surrounding area that may have been impacted by dredge residuals. If RALs are not achieved or PTW is present below the feasible depth limit of the excavation technology, as approved by EPA, a cap is assumed to be placed after dredging, as described in Section 14.2.9, Design Requirements, and per the decision tree in Figure 28 in Appendix I. Navigation and maintenance dredge depth requirements will need to be considered during design and implementation of the Selected Remedy such that the final constructed elevation is below the authorized depth of the navigation channel including an overdredge allowance/buffer zone. Implementing the Selected Remedy in the navigation channel will also need to consider and be coordinated with cleanup conducted in the rest of the Site to minimize recontamination. This cleanup may occur at the same time or later than the other cleanup actions.

#### **14.2.2. Future Maintenance Dredge (FMD) Areas**

FMD areas are those locations in the river that are periodically dredged to allow continued marine activity such as vessel activity, shipping, docking, etc. Contaminated sediment will be dredged to the depth of the Site-wide RAL concentrations shown in Table 21 in Appendix II or

to a depth required to allow placement of a cap or backfill sufficient to be effective over the long term. Where RALs are achieved through dredging, placement of a residual layer will occur as soon as is practicable following dredging within the prism and surrounding area that may have been impacted by dredge residuals. NAPL or PTW that cannot be reliably contained will be dredged unless it is present below the feasible depth limit of excavation technology, in which case it will be capped as described in Section 14.2.9, Design Requirements, and as approved by EPA. A reactive residual layer (sand plus activated carbon) is assumed after dredging if PTW that can be contained lies below the feasible limits of excavation, as described in Section 14.2.9, Design Requirements. Maintenance dredge depth requirements will need to be considered during design and implementation of the Selected Remedy such that the final constructed elevation is below the maintained depth, including an overdredge allowance or buffer zone.

### **14.2.3. Intermediate Region**

The intermediate region is defined as outside the horizontal limits of the navigation channel and FMD areas to the riverbed elevation of approximately -2 ft CRD. In this region, avoiding or minimizing impacts to the aquatic environment and floodway need to be considered and evaluated to meet CWA (Section 404) and federal floodway requirements as well as climate change impacts. In the intermediate region, contaminated sediment will be dredged to the depth required to achieve RALs (see Table 21 in Appendix II) and remove PTW, or to a depth required to allow placement of cap or backfill material sufficient to be effective over the long term as described in the Section 14.2.9, Design Requirements. The elevation of the top of the cap will be no higher than the pre-design elevation to avoid impacts to the floodway. EPA estimates the dredging depth required to accommodate a cap will generally be 5 feet. The final depth will be determined in remedial design. Where RAL concentrations are achieved through dredging, placement of a residual layer will occur as soon as is practicable following dredging within the prism and surrounding area that may have been impacted by dredge residuals. In the intermediate regions, residual layers will consist of sand (amended with activated carbon if determined to be appropriate) to prevent the transport and release of contaminants from dredge residuals. NAPL or PTW that cannot be reliably contained will be dredged unless it is present below the feasible depth limit of excavation technology, in which case it will be capped as described in Section 14.2.9, Design Requirements, and as approved by EPA. During design and construction, the final elevation of capped and dredged areas will be considered such that the leave surface of the constructed remedy is appropriate for the post-construction use of each specific area. Under any scenario, the elevation of the top of the cap or residual layer will be no higher than the pre-design elevation to avoid loss of submerged aquatic habitat, preserve slope stability, and negate adverse impacts to the floodway. If appropriate to protect sensitive species, a habitat layer will be incorporated into the constructed remedy.

### **14.2.4. Shallow Region**

The shallow region is defined as shoreward of the riverbed elevation of approximately -2 ft CRD. In this region, avoiding or minimizing impacts to the aquatic environment and floodway need to be considered and evaluated to meet CWA (Section 404) and federal floodway requirements as well as climate change impacts. Contaminated sediment in this area will be

dredged to the depth required to remove all NAPL or PTW that cannot be reliably contained (see Table 21 in Appendix II), unless it is present below the feasible depth limit of excavation technology, in which case it will be capped as described in Section 14.2.9, Design Requirements, and as approved by EPA in accordance with the decision tree shown in Figure 28 in Appendix I. Where PTW is not present but the depth of excavation to achieve RAL concentrations is greater than 5 feet, the area will be dredged to 5 feet with placement of a cap and backfilled to grade (capped per design requirements in Section 14.2.9, Design Requirements). Under any scenario, the elevation of the top of the cap or residual layer will be no higher than the pre-design elevation to avoid loss of submerged aquatic habitat, preserve slope stability, and negate adverse impacts to the floodway. In the shallow regions, a habitat layer such as beach mix will be used for the final layer of clean cover in both residual management areas and capped areas to bring the surface back to the original (pre-dredge) elevation and in order to maintain the natural habitat.

#### **14.2.5. River Bank Region**

River banks are defined as areas from top of bank down to the river that may be contaminated along the shoreline next to contaminated in-river shallow areas. Remediation of contaminated river banks is included in the Selected Remedy where it is determined that it should be conducted in conjunction with the in-river actions and to protect the remedy (Figure 9 in Appendix I and Table 21 in Appendix II). Other river banks may be included in the remedial action if contamination contiguous with contaminated river sediment is found during remedial design sampling. Engineered caps or vegetation with beach mix will be placed as the final cover based on area-specific designs, which will account for appropriate slope according to the programmatic or site specific Biological Opinion, as appropriate. NAPL or PTW that cannot be reliably contained, if present, will be fully excavated and not capped unless it is present below the depth limit of excavation technology, as approved by EPA. In those locations, a significantly augmented cap will be constructed below the habitat layer, as described in Section 14.2.9, Design Requirements. The State may also undertake actions at some river banks that are the subject of this ROD, to expedite source control of contaminated upland areas, as necessary. Those actions will be consistent with the Selected Remedy and meet CERCLA requirements.

#### **14.2.6. Institutional Controls**

The ICs used at the Site must: (1) prevent or minimize exposure by humans, wildlife, and aquatic receptors to contaminated sediment and groundwater contained by an engineered cap or other cover at the Site or left in the subsurface; (2) prevent or minimize human, wildlife, and aquatic exposure to contaminated fish and shellfish and to contaminated sediment and groundwater during construction of the Selected Remedy; and (3) maintain the integrity of the engineered components of the Selected Remedy. The ICs implemented to reduce human exposure to contaminated fish will include, but may not be limited to, fish consumption advisories and educating the community by conducting an enhanced community outreach program on a short-term and long-term basis until RAOs are achieved. The ICs used to prevent or minimize human exposure to contaminated fish, groundwater, sediment, and surface water may also include limiting land and waterway uses or activities on a short-term basis during implementation of the remedy and on a long-term basis after implementation of the remedy until RAOs are achieved.

The ICs used to protect caps or other covers and otherwise prevent recontamination in perpetuity include, but may not be limited to, limiting waterway and land use activities that may disturb or reduce the cap's or cover's ability to contain the contaminated sediment or groundwater. Other types of controls that likely will be used for caps or areas with known subsurface contamination include coordinated permit reviews of in-river work (e.g., maintenance dredging, pile removal) and other government controls to minimize recontamination to the Site. An ICIAP will be developed during remedial design which will, at a minimum, set out the specifics of the ICs and measures that will be implemented and who is responsible for implementing, enforcing, and monitoring each IC. Among others, three types of ICs that will be used are described further below:

- **Fish Advisories and Educational Outreach:** Fish advisories and educational outreach will be necessary at the Site since unlimited fish consumption is not possible. Once construction is completed, the CERCLA cleanup-related advisory may be updated to adjust consumption rates based on fish tissue concentrations. Fish advisories will distinguish between anadromous species (e.g., spring Chinook, steelhead, coho, shad, and lamprey) and resident species (e.g., smallmouth bass, brown bullhead, black crappie, and carp). Anadromous species likely have lower contaminant levels and are targeted by a wider and more diverse group of anglers. Resident fish generally have higher levels of contamination because their range is within Portland Harbor, and these types of fish are more targeted by, and more likely to be eaten by, local residents. The advisory is expected to be periodically updated until RAOs and cleanup levels are reached. The outreach program may include: informational meetings, presentations, and workshops targeting affected community groups; development and distribution of informational materials such as brochures or maps; advisory notifications communicated through a variety of culturally appropriate outlets; installation and maintenance of advisory signs at known fishing locations; and coordination with sport or recreational fishing clubs and licensing locations.
- **Waterway Use Restrictions or Regulated Navigation Areas:** Where caps will be utilized to contain contamination in navigable areas of the river, waterway use restrictions or RNAs will be necessary to ensure that the integrity of the cap is maintained in perpetuity. These restrictions may preclude boat anchoring and keel dragging, the use of spuds to stabilize vessels, structure and utility maintenance and repair, and future maintenance activities in areas containing caps. Notifications such as signs and buoys coordinated with the appropriate federal and/or state authorities (e.g., Oregon Marine Board and U.S. Coast Guard) may be used to warn vessels away from the area. Periodic inspections of RNA notifications will be needed to ensure they are functional and effective and will be evaluated in five-year reviews.
- **Land Use/Access Restrictions:** Land use or access restrictions will be needed in nearshore areas and river banks to maintain the integrity of caps from existing or future activities, such as construction and maintenance of structures and also to protect habitat areas, including compensatory mitigation projects, put in place as a part of the cleanup.

Temporary access restrictions may also be needed in river bank, beach, and in-river areas accessible by people to accomplish the cleanup. DSL has control of state-owned submerged or submersible land that may be subjected to remedial action. Adjacent landowners also may control submerged land and river banks. Coordination with DSL and adjacent landowners will be needed to implement land use or access restrictions. Monitoring, including inspections, will be needed to ensure that restrictions are functioning as intended and will be evaluated in statutory five-year reviews.

Additional IC mechanisms may be developed during remedial design and remedial action to assure all IC objectives are met and the remedy is protective. Other types of controls that likely will be used include coordinated permit reviews of in-river work (e.g., maintenance dredging, pile removal) that will be necessary to minimize recontamination to the Site. It is also possible other ICs may be developed and implemented post-construction completion.

#### **14.2.7. Monitoring Requirements**

Monitoring is a crucial part of EPA's cleanup plan. Monitoring will be conducted to evaluate short- and long-term effectiveness of the remedy and compliance with ARARs before, during, and after construction. Monitoring requirements during construction and post construction (e.g., number and location of samples and analytical parameters) will be fully developed in the remedial design. Analytical parameters will include the Site COCs for all media and other parameters deemed necessary for each phase of the project in order to comply with ARARs and determine when cleanup levels are achieved. Long-term monitoring of the remedy will be defined in future long-term monitoring plans to assess the ability of the remedy to achieve RAOs, cleanup levels, and reduce the contaminant load to the Columbia River and Multnomah Channel, and to provide information for O&M activities, and for use in five-year reviews.

##### *Baseline and Remedial Design Data Collection*

Significant remedial design sampling to determine existing baseline levels of contamination and to design the cleanup will be conducted before construction begins. Baseline sampling will be done to identify existing conditions at the Site and will include a statistically valid data set for sediment, river banks, surface water, groundwater, pore water, and fish tissue samples. This will include a statistically valid number of samples and use of the 95% UCL for both surface and subsurface sediment concentrations in and near where contamination was identified in the RI/FS to determine SWAC(s) and for the purposes of applying the decision tree, as well as in proceeding with the design of active remediation throughout the Site. Data will be collected consistent with EPA-approved RI/FS decision rules on data collection (e.g., treatment of a non-detect value) and will be evaluated on spatial and temporal scales appropriate for the RAOs. Baseline sampling will also be conducted in areas upstream and downstream of the Site. The RAO 8 cleanup levels are focused on reducing the migration of COCs in groundwater to sediment and surface water. As a result, the groundwater source control measures should be designed to prevent all surface water and groundwater COCs from discharging in exceedance of the cleanup levels, and carbon (C) 10–C12 aliphatic hydrocarbons from discharging to the Willamette River at concentrations exceeding 2.6 µg/L. Pre-design characterization activities

should, therefore, include characterization of C10–C12 aliphatic hydrocarbons using the best available detection limits possible.

#### *Monitoring During Construction*

During active remediation activities (e.g., dredging, capping, placement of clean sediment for ENR), monitoring will be conducted in the construction area, as appropriate. The cleanup activities performed in the river will need to comply with water quality standards near where the activity is taking place. Air samples may be collected to ensure contaminants do not exceed worker health-based concentration levels in air. If contaminant levels exceed water or air quality standards, the work will be modified and/or additional controls will be taken, as needed. In addition, collection of sediment, surface water, pore water, and fish tissue samples will be conducted regularly during the construction period to evaluate construction impacts and to update BMPs and ICs as needed.

#### *Long-term Monitoring*

Following construction, long-term monitoring will be conducted. The long-term monitoring program will include sediment, river banks, surface water, groundwater, pore water, and fish tissue samples from upstream, within, and downstream of the Site. Fish tagging may be conducted to better understand home ranges of particular resident species, such as small mouth bass, to appropriately assess the progress of cleanup by SMA. Passive samplers may also be used to supplement fish tissue data as a surrogate for fish tissue. Data on contaminant levels will be used for multiple purposes, to determine if natural recovery is occurring as expected or if any additional actions are required to achieve the cleanup goals within the planned timeline; track if fish tissue concentrations are decreasing; and monitor if the caps are effectively containing the contaminated sediment and/or groundwater. Data on contaminant levels in fish tissue will also help inform when and how the fish consumption advisory or other restrictions could be relaxed.

Long-term monitoring will also include regular inspections of the entire remedy, including sediment caps, to ensure they: are effectively containing migration of COCs from reaching the biologically active area of sediment, including pore water, and the water column in the river; are in the proper place; have the required thickness and type of capping material; are achieving cleanup levels; and are otherwise functioning as intended. Benthic toxicity testing may be utilized where all other cleanup levels are met, should benthic cleanup levels not be achieved in a reasonable time frame. Long-term monitoring of compensatory mitigation projects will be necessary to ensure they are providing the habitat functions and services they are designed to provide. Inspections may also be required after natural events such as earthquakes or floods, and manmade events such as boat collisions or violations of land use restrictions (e.g., vessel grounding, anchoring in an RNA area). Long-term monitoring and maintenance of the caps will be required in perpetuity.

#### **14.2.8. Five-Year Reviews**

Since the Selected Remedy will leave contamination in place above levels that allow unlimited use and unrestricted exposure, as required by CERCLA, a statutory review will be conducted

within five years after initiation of the remedial action to ensure that the remedy is, or will be, protective of human health and the environment. Five-year reviews are expected to be conducted in perpetuity.

#### **14.2.9. Design Requirements**

##### **14.2.9.1. Capping**

**General Capping Requirements:** All caps will be of sufficient thickness to prevent exposure and will be constructed of materials adequate to contain contamination remaining beneath the cap. Additionally, all caps will be constructed with sufficient armor material to remain in place when subject to erosive forces resulting from wind and vessel generated waves, current, or propeller wash while minimizing adverse effects on the in-river and riparian habitat, including the loss of shallow water habitat.

In habitat areas, currently defined by NMFS as those areas above -15 ft CRD, post-remedy surfaces will be maintained at their current depth and backfilled or capped with suitable habitat materials. As part of the remedial design, EPA, in coordination with natural resource agencies and tribes, will determine what areas are considered in-river habitat areas and on the river bank for the purpose of complying with ESA and Section 404 of the CWA. EPA will also determine what elevations and what substrate materials will be required for caps, ENR, or placement of backfill materials in any identified habitat area to minimize adverse impacts to the aquatic environment while also ensuring that the material will remain in place.

Cap construction will consider the ability of the sediment bed to support the cap during placement. Caps will also be designed to withstand more frequent floods with higher peak flows more common with climate change. Caps will also factor in appropriate earthquake design elements for contingency level events. If caps are required within the navigation channel and future maintenance dredge areas, work will be coordinated with USACE to ensure that the cap is compatible with current and anticipated waterway use. Any proposed capping in the navigation channel and future maintenance dredge areas will consider the current and authorized channel depth, the potential for an increase to the currently authorized channel depth, future navigation and maintenance dredging, and an appropriate buffer depth to ensure the integrity of the cap.

Cap design will also consider the following design elements:

- **PTW (NAPL/Not Reliably Contained) – Significantly Augmented Cap:** Cap design will include organoclay, other reactive material, and/or low permeability material, as necessary, to provide a sufficient chemical isolation layer to reliably contain underlying contamination (i.e., to pore water cleanup values).
- **PTW (Highly Toxic) – Reactive Cap:** Cap design may require the use of activated carbon and/or other reactive material, as necessary, to meet RAOs.
- **Areas of Groundwater Contamination and/or Pore Water Exceedance - Reactive Cap:** Cap design will require the use of activated carbon, other reactive material, and/or

low permeability materials, as necessary, to prevent contaminant migration through the cap, accounting for the degrees of upland source control.

- **Structures:** Caps placed below or adjacent to structures will consider the logistics of placing capping material below structures and any physical constraints adjacent to the structure including sediment bed slope, current and future navigation uses, and propeller wash. Minor structures, such as outfalls, will be moved to accommodate dredging and capping when necessary.
- **Debris:** Cap design will consider the presence or absence of debris. Any debris that hinders expected cap performance will be removed prior to cap placement unless it can be demonstrated that the debris is infeasible to remove.
- **Slope:** Cap design will consider the slope of the sediment bed. Sediment caps will be designed to remain in place. This may require removal of material to lessen the slope angle or incorporation of buttresses at the base of the slope to maintain stability and promote establishing habitats.
- **Flood Rise and Navigation:** Caps will be designed to avoid adverse impacts to the floodway, consistent with the Executive Orders for Floodplain Management (Executive Orders 11988 and 13690) and FEMA regulations. Additionally, caps will be designed to avoid adverse impacts to current and future navigation based on expected cap thickness, authorized channel depth, and appropriate buffer. This may limit cap construction in some locations or require removal of contaminated sediment prior to cap placement.
- **Land and In-River Use:** Caps will need to be designed consistent with anticipated uses so that the cap is not destroyed or damaged by those uses.
- Additional requirements may be determined during remedial design and in coordination with NMFS and U.S. Fish and Wildlife Service (USFWS) to comply with ARARs.

#### 14.2.9.2. Dredging

**General Dredging Requirements:** Dredging designs will consider the lateral and vertical extent of contamination. The lateral extent of contamination will be based on the SMAs (RALs and PTW; see Section 14.2.7, Monitoring Requirements). The vertical extent of contamination will be based on the decision tree in Figure 28 in Appendix I. Dredging design will also consider the following elements:

- **Residual Management:** Residual management layers will be placed as soon as is practicable following dredging within the prism and surrounding area and are assumed to be 12 inches in thickness. In the navigation channel and FMD and intermediate regions, residual layers will consist of sand (amended with activated carbon, as necessary) to prevent exposure to residuals above cleanup levels. In the shallow region, residual management will consist of capping or backfilling to grade to prevent exposure above cleanup levels and to minimize adverse effects on in-river and riparian habitat, including the loss of shallow water habitat.

- **Structures:** Structures may be removed to access contaminated media unless it can be demonstrated that the structure is permanent (e.g., not floating or movable), functional (e.g. not beyond its design life and/or in disrepair), or needed for current or future property and waterway use. Minor structures, such as outfalls, will be moved to accommodate dredging and capping when necessary.
- **Debris:** Dredging design will consider the presence or absence of debris. Any debris that limits access to contaminated media or reduces short-term effectiveness during dredging must be removed prior to dredging unless it can be demonstrated that the debris is technically infeasible to remove.
- **Water Quality Controls:** Water quality controls, including silt curtains and/or rigid containment (e.g., sheet pile wall enclosures) may be required to minimize releases to the water column associated with the presence of contaminated sediments, NAPL, debris, and other chemical or physical conditions to comply with water quality standards. Additional requirements may be determined during remedial design and in coordination with NMFS and USFWS to comply with ARARs.
- **Disposal:** All dredged or excavated materials will be tested to determine whether treatment is necessary prior to disposal and to determine appropriate disposal locations. Treatment will be required per regulations, requirements of the disposal facility, or whether the waste material is subject to the 2004 MGP dispute decision. Appropriate disposal locations will be based on waste characterization and ARARs.
- Where dredging has been completed in accordance with the RALs, additional dredging may be necessary to accommodate reactive caps, which would be required to meet cleanup goals in pore water.

#### 14.2.9.3. In-Situ Treatment

**In-Situ Treatment Requirements:** In-situ treatment will be accomplished through the placement of a reactive layer of activated carbon in powdered or granular form. Placement may be through broadcast placement of sand mixed with activated carbon or use of a commercial product such as AquaGate +PAC (or equivalent). The concentration of the placed activated carbon will be determined during remedial design but must limit bioavailability sufficiently to meet the RAOs and cleanup levels for the Site and minimize the potential for adverse impacts to the benthic community and other aquatic organisms.

#### 14.2.9.4. Enhanced Natural Recovery

**Enhanced Natural Recovery Requirements:** Enhanced natural recovery will be accomplished through the placement of sufficient material, assumed to be 12 inches of sand or other appropriate benthic substrate, to meet the RAOs and cleanup levels established for the Site over time. Timing of the placement of ENR materials may be adjusted or sequenced to avoid undue acute impacts to the benthic environment. Where empirical data indicates that MNR may be sufficient to meet clean up goals in a reasonable time frame, MNR will be considered in lieu of an ENR technology assignment, such as in Swan Island lagoon.

#### 14.2.9.5. River Banks

**General River Bank Requirements:** In an SMA, contaminated river banks will be remediated through this cleanup where they are contiguous with in-river contamination or where they pose a risk of recontamination to the Selected Remedy. These cleanups will be conducted in a manner that is compatible with the Selected Remedy and minimizes adverse impacts to riparian habitat including minimizing slope angle and the use of hardened banks to prevent erosion. The state may also undertake some response action for river banks that are the subject of this ROD, to expedite source control of contaminated upland areas, as necessary. Those actions will be consistent with the Selected Remedy and meet CERCLA requirements.

#### 14.2.10. Performance Standards

Performance standards related to implementation of the Selected Remedy will be fully developed during the remedial design and will be based on environmental media (e.g. sediment, groundwater, surface water, etc.) and scientific criteria. The performance standards will be incorporated into all relevant remedial design documents. The standards will promote accountability and ensure that the remedy meets the RAOs, Site-specific ARARs, and cleanup levels. Fish and shellfish tissue values will be used as a qualitative performance standard metric, as well as to update CERCLA related advisories. Likewise, contaminant loading to the Multnomah Channel and Columbia River will be evaluated generally to ensure decreasing trends over time and that any elevated levels during construction are mitigated to the extent practicable. Compensatory mitigation projects, should they be needed, will include performance standards such as native plant coverage, invasive species limits, and target species presence (vs. absence).

#### 14.2.11. Remedy Implementation

Due to the size of the Site and the breadth of contamination, implementation of the Selected Remedy may need to be conducted in phases and/or work sequenced. To implement the remedy, EPA will consider, at a minimum, source control actions, recontamination potential, scope (size) of the actions across the Site, impacts to the river users and the community, seasonal weather impacts, fish windows, and implementation approaches the parties that agree to perform the cleanup may suggest.

While such decisions have not yet been made, EPA may manage the Portland Harbor cleanup by dividing the Site into smaller work areas for purposes of design and construction activities based on factors such as prioritization of significant source areas, logistics, efficiency, or other factors. Sequencing of cleanup may consider factors such as potential impacts of upstream work on downstream areas, including but not limited to, the potential for resuspension of contaminants during construction, nature and extent of contamination, and integration of the cleanup actions into the overall Site remedy.

#### 14.2.12. Use of Green Remediation Practices

To the extent practicable, the remedial action should be carried out consistent with EPA Region 10's Clean and Green policy (EPA 2009) and the Superfund Green Remediation Strategy (EPA 2010), including the following practices:

- Use renewable energy and energy conservation and efficiency approaches, including Energy Star equipment.
- Use cleaner fuels such as low-sulfur fuel or biodiesel, diesel emissions controls and retrofits, and emission reduction strategies.
- Use water conservation and efficiency approaches including Water Sense products.
- Use reused or recycled materials within regulatory requirements.
- Minimize transportation of materials and use rail rather than truck transport to the extent practicable.

### **14.3. Summary of Estimated Selected Remedy Costs**

Total present value costs estimated for the Selected Remedy are \$1,054,200,000. The total capital cost is \$1,184,607,000 and the total periodic costs are \$524,028,000. Detailed costs associated with implementing the Selected Remedy are presented in Table 28 in Appendix II. The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the Selected Remedy. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the Selected Remedy. Major changes may be documented in the form of a memorandum in the Administrative Record file, an ESD, or a ROD amendment. The cost estimate is an order-of-magnitude engineering estimate that is expected to be within +50 to -30% of the actual project cost.

### **14.4. Expected Outcomes of Selected Remedy**

The intent of the Selected Remedy is to be protective of human health and the environment by reducing risks from the following: fish and shellfish consumption, direct contact with sediment and surface water, ingestion of sediment and surface water, groundwater, prey, and resuspension of contaminated sediment that act as an ongoing source of contamination. The Selected Remedy will actively address contaminated sediment and groundwater within the Site, thereby reducing exposure to contaminant concentrations in other media such as surface water and fish tissue, which will significantly reduce human health and ecological risks at the Site to acceptable levels. Remediation of the sediment in the Site will also reduce migration of contaminants to Multnomah Channel and the Columbia River. Addressing areas with contaminated groundwater by dredging and capping will also reduce loading to surface water and reduce exposure to benthic invertebrate organisms living in sediment. Remediation of contaminated river banks is included in the Selected Remedy where it is determined that it should be conducted in conjunction with the in-river actions, thereby eliminating additional sources of contamination that impact river sediment and water quality.

The Selected Remedy includes response actions to address contamination within the in-river portion of the Site and associated river banks. There are known sources of contamination in the upland areas of the Site and known sources in locations in the downtown reach of the river (approximately RM 12 to RM 16.6). EPA is relying on the Oregon DEQ to use its authorities to address these sources. It is expected that controlling these sources will reduce or eliminate contamination in soil, groundwater, storm water, and surface water that migrates to the

Willamette River. Since the achievement of cleanup levels identified in the Selected Remedy relies in part upon timely and successful completion of these upland and upstream source area actions, EPA retains the discretion to use its federal authorities to complete those actions.

Implementation of the Selected Remedy will result in improvements in the overall river habitat, with positive impacts on all species that use the river, including freshwater rearing sites and migration corridors that are essential to the conservation of the listed salmonid species and species that have a role in Tribal lifestyles.

The goal of this CERCLA cleanup action is to reduce in-river contamination, including river banks, to levels needed to achieve all cleanup levels (Table 17 in Appendix II) and ARARs Tables 25a-c in Appendix II. The Selected Remedy will attain ARARs, although some ARARs may not be achieved for a longer period of time. The Selected Remedy is consistent with current and reasonably anticipated future uses of the river. Institutional controls that limit resident fish and shellfish consumption will have to remain in effect to ensure protectiveness for the foreseeable future but will be relaxed over time as cleanup is completed. ICs that protect engineered components of the remedy that contain contamination in place will be required in perpetuity.

A final CERCLA remedial action was completed at the McCormick and Baxter Site (RM 7 east) in 2005 and, therefore, the area within the river addressed by that ROD is not included in the Selected Remedy.

The Selected Remedy will also be consistent with the reasonably anticipated future river uses by recreationalists, Tribal users, subsistence fishers, and industry. Additionally, the Selected Remedy is consistent with the federally-authorized navigation channel, by limiting cap placement within the navigation channel and areas where maintenance dredging may occur and considering the presence of permanent structures.

The Selected Remedy will include an estimated total constructed area of 394 acres of sediment and approximately 23,300 lineal feet (or 20% of river banks) and will allow 1,774 acres of sediment to naturally recover. The sediment removed from the Site, 3,017,000 cy, will be sent to off-site disposal facilities after testing to determine the appropriate disposal facility.

Approximately 123,000 cy of contaminated material from river banks will be excavated for off-site disposal.

The active remedy components of the Selected Remedy are expected to take approximately 13 years to implement after completion of the remedial designs. As in-river work will be limited to about 4 months a year due to restrictions to protect migratory species, construction work will proceed incrementally and may take approximately 13 years to complete once it begins unless construction is allowed to occur outside this construction window, as approved by the resource agencies, which could shorten the timeframe. It is expected that certain areas of the in-river work will be completed prior to other areas and will be sequenced based on a number of factors mentioned in Section 14.2.11. During and after remediation, current and anticipated future land and waterway uses, including industrial, residential, commercial and recreational uses, are

expected to be able to continue, subject to the institutional controls and so long as sources of contamination are controlled or eliminated.

Long-term monitoring of the Selected Remedy will be conducted to ensure MNR occurs and cleanup levels and RAOs are achieved. Long-term monitoring will also be conducted to evaluate the integrity of caps and overall protectiveness of the remedy. Any identified deficiencies in the caps will be addressed in an expeditious fashion in accordance with an O&M plan, to be developed during remedial design to ensure the continued protectiveness of the Selected Remedy.

EPA expects that, once the Selected Remedy (dredging, capping, ICs, ENR, and MNR) has been implemented and long-term monitoring shows COC concentrations have reached a steady state, COC concentrations will either be at cleanup levels for sediment, surface water, and groundwater, or will represent practicable limitations in implementation of source control and active remediation. Data collection and analysis during long-term monitoring, compiled and analyzed in five-year reviews, is intended to test this expectation.

However, if EPA determines that additional remedial action is appropriate for the in-river portion of the Site, EPA will select such action in a ROD Amendment or ESD. If EPA determines that further upland or upriver source control is appropriate, EPA or DEQ will address such sources with source control response action decisions separate from this ROD. If EPA determines that no additional practicable actions can be implemented under CERCLA to meet ARARs or cleanup levels, EPA may issue a ROD Amendment or ESD providing the basis for a technical impracticability waiver for specified sediment and/or surface water quality- or groundwater-based ARARs under CERCLA.

Implementation of the Selected Remedy will substantially improve the quality of sediments and surface water in Portland Harbor, reduce COC concentrations in waterway organisms, reduce contaminant loading to the Columbia River and Multnomah Channel, and result in a reduction in fish consumption risk.

The Portland Harbor Superfund cleanup addresses the lowest 10 miles of the Willamette River, which drains about 408 square miles of land in Portland, Oregon. This is a small part of the 187-mile long river which in its entirety drains 11,460 square miles or 12% of the State of Oregon. Although sediment cleanup and related source control efforts will greatly improve water quality in the Site and downstream areas, other efforts in addition to, or coordinated with, Superfund authorities can improve the overall environment of the watershed. By coordinating work between multiple programs, these other efforts will complement the work conducted within the Site.

Generally, under CERCLA, cleanup levels are not set at concentrations below natural background levels. Similarly, for anthropogenic contaminant concentrations, EPA generally does not establish cleanup levels at Superfund sites below anthropogenic background concentrations. As background contaminant concentrations contributing to Portland Harbor exceed risk-based numbers, the Selected Remedy uses these background concentrations to establish cleanup levels. Because the larger watershed contamination is beyond the scope of the Selected Remedy, EPA and the state will coordinate actions under other authorities within the larger watershed that focus

on reducing contaminant loading to the watershed as well as improving overall environmental conditions.

One component of this strategy includes an effort to identify sources of contamination within the broader watershed. EPA and the state are committed to compiling existing watershed contamination data, identifying data gaps, evaluating the efficacy of existing efforts, and identifying new strategies to reduce contaminant loading in the watershed. These efforts will use all appropriate regulatory authorities, including the CWA and federal and state authorities, and will be conducted in collaboration between EPA, the state, local government, the tribes, and other interested entities, and will build on other current and planned efforts throughout the Willamette and Columbia River watersheds. Current efforts led by the state, municipal agencies, local organizations, and other federal entities include, but are not limited to, infrastructure improvements, habitat restoration, recent promulgation of human health water quality criteria based on an increased fish consumption rate, total maximum daily load (TMDL) development and implementation, geographical NPDES permit requirements, toxics reduction strategies, monitoring, CSO abatement, pesticides education and collection, and comprehensive upland source control efforts. In addition, Superfund site assessment and sampling efforts to review additional areas beyond the boundaries of the existing Site may be used to identify additional actions to be taken under Superfund or state law.

## **15. STATUTORY DETERMINATIONS**

CERCLA §121(b)(1) and (d) require selection of a remedy or remedies that are protective of human health and the environment, comply with ARARs (unless a statutory waiver is justified), are cost-effective, and use permanent solutions and alternative treatment technologies to the maximum extent practicable. In addition, CERCLA includes a preference for remedies that employ treatment that permanently and significantly reduces the volume, toxicity, or mobility of hazardous substances, pollutants, or contaminants as a principal element.

EPA has determined that the Selected Remedy meets these statutory requirements. As required by the NCP §300.430(f)(5)(ii), below is a description of how these statutory requirements are met.

### **15.1. Protection of Human Health and the Environment**

The Selected Remedy will address the unacceptable risks to human health and the environment through capping, dredging, and ENR of an estimated 394 acres of contaminated sediments and approximately 23,300 lineal feet of contaminated river banks. An additional 1,774 acres will be addressed with MNR to further reduce post-construction risks. ICs will also be required as part of the remedy. While areas of the river will take less time to construct, it is expected that the overall construction duration for the Selected Remedy is estimated to be 13 years, with no additional time required to complete dredged material processing. Resuspension/release during construction activities will be addressed through operational BMPs and engineered control measures, where necessary. Institutional controls to restrict land uses, such as Waterway Use Restrictions, RNAs, or environmental easements and equitable servitudes, will be implemented to protect the integrity of the caps and ensure residual risks are contained within the capped

areas. Additionally, coordination with federal and state regulatory authorities on future permitting actions in the river that may affect caps or other covers, or releases of subsurface contamination will likely be needed.

The Selected Remedy is expected to be protective of human health and the environment once cleanup levels are achieved. Cleanup levels will be achieved through implementation of a combination of dredging, capping, ENR, and MNR. Although a period of time is required to achieve all cleanup levels, significant risk reduction will be achieved the end of construction. At the end of construction, cleanup levels protective of wildlife that consume prey will be achieved, and people will be protected from risks associated with playing on beaches and swimming in the river. Short-term and long-term protection of human health from eating contaminated fish will be achieved through a combination of sediment remediation, fish consumption advisories, and other ICs. After active cleanup, MNR is projected to achieve cleanup levels within a reasonable time frame. Since a model was not capable of predicting accurately how long MNR would take, monitoring will be necessary to determine whether natural recovery is occurring at a rate sufficient to meet cleanup levels in a reasonable time frame. Based on criteria developed in the MNR monitoring plan, additional actions may be necessary if it is determined that MNR will not achieve cleanup levels. Those additional actions will be documented in a future decision document.

After the remedy has been constructed, adults will be able to eat 16 fish meals per year after cleanup. When cleanup levels are achieved, adults will be able to eat 27 fish meals per year (based on a  $1 \times 10^{-5}$  risk) and children (based on HI of 1) will be able to eat 30 fish meals per year. Current fish advisories instruct people to avoid or limit eating bass, carp, and catfish. For some contaminants like PCBs, background anthropogenic levels exceed levels that would be protective of unlimited consumption of resident fish. Therefore, people will need to restrict their consumption of resident fish even after the Superfund cleanup levels have been achieved since Superfund, as a matter of policy, does not address contamination below these background levels. A discussion of how the Selected Remedy performs is presented below by RAO.

During implementation of the Selected Remedy, construction is not expected to pose unacceptable short-term risks or cross-media impacts. As mentioned previously, monitoring during construction will be conducted to assess these impacts and make adjustments as needed.

#### **15.1.1. Human Health RAOs**

Post-construction risk numbers are provided in Table 22 in Appendix II and are summarized below:

##### *RAO 1: Sediment*

Immediately after construction of the Selected Remedy, people will be safe when coming into contact with sediments because the carcinogenic risks are estimated to be no higher than  $1.0 \times 10^{-5}$ , which is within EPA's range of acceptable risk. Additional risk reduction will be achieved over time through MNR, with a long-term objective of achieving  $1 \times 10^{-6}$  risk or background.

### *RAO 2: Biota*

Within a few years after construction of the remedy, carcinogenic risks from eating contaminated fish (on a Site-wide scale) will be  $1.5 \times 10^{-4}$ , which is within EPA's acceptable risk range but is not in compliance with Oregon law (cited in Section 15.2.1 below) regarding risk reduction to be no greater than  $1 \times 10^{-5}$  cancer risk. Non-cancer risk after cleanup is expected to be 15 for the child receptor. In addition, within a few years of construction, it is estimated that adults (other than women who are or plan to breastfeed) will be able to eat about 16 fish meals per year based on a Site-wide scale. Prior to cleanup, current fish advisories suggest people should avoid eating bass, carp, and catfish. Once cleanup levels are achieved, adults will be able to safely eat about 27 fish meals per year (other than the sensitive population cited earlier), which is based on anthropogenic background risk for PCBs.

Under the Selected Remedy, fish consumption advisories will be required as part of the Superfund action until such time as RAO 2 is achieved. Outreach more fully described in Section 14.2.6 will be conducted to educate the public about the fish consumption advisories. Informational materials will be needed and evaluated to determine advisory effectiveness. Due to the presence of contaminants upstream of the Site and within the Willamette River watershed, it is unlikely that fish advisories would ever be removed.

### *RAO 3: Surface Water*

After construction of the Selected Remedy, it is estimated that all surface water COC concentrations will be reduced to 10 times the cleanup levels. Over time, it is expected that cleanup levels (both risk-based and ARAR-based surface water levels) will be achieved through a combination of in-river cleanup combined with source control actions within the site as well as actions taken to address toxics within the watershed.

### *RAO 4: Groundwater*

The Selected Remedy will address 39% of the river bottom impacted by groundwater plumes through construction; the remainder of the contaminated groundwater will be dependent on the adequacy of source control actions.

## **15.1.2. Ecological RAOs**

### *RAO 5: Sediment*

At the end of cleanup construction, the Selected Remedy will address 72% of the area based on 10 times unacceptable benthic risks. The remainder of the benthic risk areas will be left to MNR and evaluated in five-year reviews.

### *RAO 6: Biota*

Immediately after construction of the Selected Remedy, it is estimated that wildlife will be able to safely consume prey from within the Site since all non-cancer risks on a Site-wide scale will be addressed. It is estimated that BEHP will be at an HQ of 5 on an RM scale and 3 on an SDU scale, very close to the target of 1 and well within potential calculation variances.

### *RAO 7: Surface Water*

All surface water cleanup levels for this RAO will be achieved through cleanup construction, other than BEHP, cPAHs, and TBT because there is insufficient surface water data to evaluate the effectiveness of the Selected Remedy for these contaminants. It is expected that MNR in conjunction with ICs and source control, including control of upriver sources, would be necessary to achieve these surface water cleanup levels over time. Ethylbenzene is expected to be addressed through RAO 8 and implementation of source control measures.

### *RAO 8: Groundwater*

The Selected Remedy will address 39% of the river bottom impacted by groundwater plumes through construction; the remainder of the contaminated groundwater discharging to the river will be dependent on the adequacy of the source control and will be evaluated in five-year reviews.

## **15.1.3. Human Health and Ecological RAO**

### *RAO 9: River Banks*

The Selected Remedy will address direct contact risks, contaminant loading, as well as risk of re-contaminating sediments in 78% of the contaminated river bank through construction. The remaining areas are expected to be addressed through other cleanup actions because natural recovery will not work for upland river bank areas.

## **15.2. Compliance with ARARs**

CERCLA §121(d) and NCP §300.430(f)(1)(ii)(B) require that remedial actions at CERCLA sites at least attain legally applicable or relevant and appropriate Federal and State requirements, standards, criteria, and limitations which are collectively referred to as "ARARs," unless such ARARs are waived under CERCLA §121(d)(4). Applicable requirements are those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal environmental or State environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. Relevant and appropriate requirements are those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal environmental or State environmental or facility siting laws that, while not "applicable" to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well-suited to the particular site.

ARARs for the Selected Remedy are shown in Tables 25a-c in Appendix II. The objective of the Selected Remedy is to meet ARARs throughout the Site.

Chemical-specific ARARs will be achieved over time through implementation of a combination of dredging, capping, ENR, and MNR. Because the Selected Remedy relies less on MNR than most other alternatives, it is expected to achieve standards more quickly. Location-specific and

action-specific ARARs will be achieved by meeting all of the substantive requirements during design, construction, implementation, and monitoring of the Selected Remedy.

#### **15.2.1. Compliance with Chemical-Specific ARARs**

For COCs identified in surface water and groundwater, Oregon's numeric toxics water quality standards (Tables 30 and 40) are applicable requirements as cleanup standards if more stringent than Clean Water Act 304(a) recommended criterion, otherwise the relevant and appropriate 304(a) criteria are the cleanup standard. Additionally, non-zero MCLGs or MCLs associated with COCs identified for surface water and groundwater are relevant and appropriate cleanup standards. Because there are no MCLs for manganese and MCPP, EPA RSLs for groundwater for those COCs are the cleanup levels shown in Table 17 in Appendix II.

Under the Selected Remedy, exceedances of water quality criteria for protection of human health will continue for PCBs, cPAHs, and 2,3,7,8-TCDD eq at the completion of construction. There is insufficient surface water data to evaluate the effectiveness of the Selected Remedy to meet the aquatic life water quality criteria for BEHP, cPAHs, and TBT at this time. It is expected that cleanup levels will be achieved for these chemicals after a period of time and after sources are reduced. The ethylbenzene standard for contaminated groundwater is expected to be achieved through implementation of source control measures and river bank work.

Implementation of the sediment remediation in combination with upland and upriver source control remedies under State-lead authority will improve surface water quality to an unknown degree. If appropriate, a waiver of surface water quality ARARs will be considered only after the improvement from these combined actions is assessed based on long-term water quality monitoring. Long-term monitoring and maintenance of engineering controls, monitoring of pore water, and surface water will assist in confirming the ability of the Selected Remedy to achieve chemical-specific ARARs. If long-term monitoring indicates that surface water quality ARARs cannot be met, EPA will review the data and consider whether additional technically practicable response action would further reduce contaminant concentrations in surface water. If EPA determines that additional remedial action is appropriate for the in-river portion of the Site, EPA will select such action in a ROD Amendment or ESD. If EPA or the State determine that further source control is appropriate, EPA or the State will address such sources with source control response action decisions separate from this ROD. If EPA determines that no additional response actions can be implemented to meet ARARs, EPA may issue a ROD Amendment or ESD providing the basis for a technical impracticability waiver for water-quality based ARARs under §121(d)(4)(C) of CERCLA.

Contaminated groundwater will be addressed through the use of on-site treatment. During design, the areas requiring reactive caps will be identified and after cleanup construction, it is expected that contaminated groundwater that enters the Site will be addressed through upland source control and the actions identified in this ROD.

Oregon's carcinogen and noncarcinogen risk standards for degree of cleanup for hazardous substances [OAR 340-122 -0040(2)(a) and (c), 0115(2-4)] are applicable standards for the final Selected Remedy to achieve. Under the Selected Remedy, Oregon's risk standards will not be

achieved at the completion of construction, but are projected to be achieved, over time through MNR, ICs, and monitoring.

During implementation of the Selected Remedy potential short-term exceedances of some water quality criteria are possible. Under state law, OAR 340-041-004, short-term degradation is allowable if the benefits of the lowered water quality outweigh the environmental costs of the reduced water quality as determined through an analysis of the specific water quality impacts and the development of a water quality monitoring plan during design. The water quality monitoring plan will specify the BMPs and other conditions and restrictions on the dredging and capping activity necessary to ensure that the activity will be conducted in a manner which will comply with state water quality standards and meet other ARAR-based surface water cleanup standards (also see CWA in Section 14.2.3, Action-Specific ARARs).

### **15.2.2. Compliance with Location-Specific ARARs**

Location-specific ARARs for the Selected Remedy will be evaluated and addressed during design and implementation of the remedy. Key location-specific ARARs are highlighted below.

#### *Endangered Species Act and Essential Fish Habitat*

ESA requires that the remedial action may not jeopardize the continued existence of endangered or threatened species or result in the adverse modification of species' critical habitat. Agencies are to avoid jeopardy or take appropriate mitigation measures to avoid jeopardy. The Magnuson-Stevens Fishery Conservation and Management Act provides for the designation of Essential Fish Habitat (EFH) for waters and substrate necessary for commercially fished species to spawn, breed, feed, or grow to maturity. Actions that may adversely affect EFH need to be coordinated with NMFS. The Selected Remedy will meet the substantive requirements of these ARARs during design, construction, and long-term monitoring. Listed species are found at the Site, and critical habitat for listed salmonids and EFH has been designated within the Site.

For the Selected Remedy, compliance with ESA and EFH requirements will be met through preparation of a programmatic and Site-specific Biological Assessment (BA). Some locations along the river, such as at Gasco and Arkema, may be evaluated separately, but most of the work within the river will fall under the programmatic assessment. The BAs will evaluate the effects to species found at the Site listed as threatened or endangered under ESA and impacts to those species' designated critical habitat and EFH from the proposed remedial activities. Such impacts will be mitigated and reduced as more remedial design information is obtained. The BA will determine whether the proposed combination of technologies and ancillary activities used to clean up the contaminated sediment and river banks may adversely affect listed species. The BA will also contain the BMPs and other mitigation measures to minimize the impacts to the species and critical habitat and EFH during construction of the remedy as well as mitigation that may be necessary to compensate for impacts to critical habitat. Long-term monitoring of the compensatory mitigation to assure it is functioning as designed will be required. A preliminary programmatic BA was developed as part of the FS and Proposed Plan, and coordination with NMFS and USFWS has begun. As remedial design progresses the BA will be supplemented to address specific issues unique to remedy implementation at a particular area within the Site. If

remedial activities may result in any take, a take permit will be requested from the Services. Additionally, all in-river construction will be coordinated with Services around fish windows where necessary.

Survival Guidelines found at OAR 635-100-0135 are rules regarding actions that affect species listed under Oregon's Threatened or Endangered Wildlife Species law. The substantive survival guidelines will be incorporated into the remedial design and implementation of the Selected Remedy.

#### *Federal Emergency Management Act*

Although not legislated law, federally approved projects need to comply with Executive Orders 11988 (Management of Floodplain), as amended by Executive Orders (E.O.) 13690 and 11990 (Protection of Wetlands). The FEMA regulations in 44 CFR Part 9 set forth the responsibilities to implement and enforce E.O. 11988, as amended by 13690 and 11990. Likewise, FEMA regulations found at 44 CFR 60.3(d)(2) and (3) prohibit encroachments that would result in any increase in flood levels during occurrence of base flood discharge. A simple analysis was conducted during the FS (see FS Appendix P) to provide a cursory assessment of the potential for the remedy on a Site-wide and smaller SDU scale to affect flood rise. A HEC-RAS hydrodynamic model will be run to support the Selected Remedy on an SMA-scale and Site-wide scale during remedial design to verify that the remedy will not result in adverse impacts to the floodway. The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy.

A more detailed evaluation of floodway impacts will be conducted, which will include consideration of the following:

- Minimize the use of remedial process options that result in a net increase of fill material placed within the river and adjoining flood plain.
- Perform detailed modeling to demonstrate that the Selected Remedy does not result in unacceptable flood rise.
- The use of natural features and nature-based approaches in the implementation of the Selected Remedy.
- Placement of structures (such as an on-site transload facility) at a higher vertical elevation to address current and future flood risks.
- The floodplain and corresponding elevations will be determined using these approaches:
  - Flood Rise: The Site-wide and SMA specific evaluations of flood rise will need to consider 500-year flood elevation and freeboard and be based on the best-available, actionable hydrologic and hydraulic data and methods that integrate current and future changes in flooding based on climate science.
  - Channel Depth: The Willamette River currently has an authorized channel depth of -40 ft CRD. Prior to listing of the Portland Harbor Superfund Site on the NPL, the

USACE proposed deepening the federally maintained navigation channel to -43 ft CRD. Deepening the navigation channel may mitigate the effects of cap and thick layer sand cover placement on flood rise associated with the sediment cleanup near the channel.

- **Climate Change:** In general, climate change is expected to result in increased winter flow, decreased summer flow, lower snow packs and earlier peak within the Willamette River. In addition, because of a lower snow pack and more frequent fall and winter rain events, more high flow events are expected but of less magnitude than the large flood events observed in the 1900s. Uncertainties associated with potential climate change will be incorporated into the flood rise evaluation and cap design elements.

#### *Native American Protected Objects and Graves Protection Preparation*

During the RI, a cultural resource analysis concluded that there are possible Native American archeological artifacts at the Site, but no gravesites were noted. The Selected Remedy will meet the substantive requirements of this ARAR during implementation of the remedy in coordination and consultation with the relevant tribes. If Native American cultural items or gravesites are present on a property, an inventory of such items will be compiled and items will be returned to the tribes.

If removal of cairn, burial, human remains, funerary objects, or other sacred objects takes place, re-interment will occur under the supervision of the appropriate Indian tribe. Any proposed excavation by a professional archaeologist of a Native American cairn or burial will require written notification to the State Historic Preservation Officer and consultation with the appropriate Indian tribe.

#### *National Historic Preservation Act (NHPA) and Archaeological Objects and Sites*

There are no known historic properties, structures, or objects included in or eligible for the National Register of Historic Places within the Site where action will be taken under the Selected Remedy. The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy if NHPA eligible properties or structures are discovered. Given that NHPA includes artifacts, records, and material remains related to a property also, if cultural resources or other archeological objects on, or eligible for, the national register or under state law are present, it will be necessary to determine, in consultation with the appropriate State Historic Preservation Office, if NHPA requirements may apply along with other requirements of the Oregon Archaeological Objects and Sites laws.

### **15.2.3 Compliance with Action-Specific ARARs**

Action-specific ARARs for the Selected Remedy will be addressed during design, implementation, and, if relevant, long-term monitoring.

## *CWA and Oregon WQS*

CWA § 404's implementing regulations known as the §404(b)(1) Guidelines, restrict the discharge of dredged or fill material if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic environment, so long as the alternative does not have other significant adverse environmental consequences (40 CFR 230.10(a)). The 404(b)(1) Guidelines include the factual determinations that need to be made on short-term and long-term effects of a proposed discharge of dredged or fill material on the physical, chemical, and biological components of the aquatic environment (40 CFR 230.11) in light of Subparts C through F of the guidelines and the findings of compliance on the restrictions (40 CFR 230.12). At this Site, compliance with the Guidelines and the analysis of the physical, chemical, and biological impacts to the aquatic environment is documented in a 404(b)(1) evaluation (FS Appendix L). Based on the 404(b)(1) evaluation, public comments, and in consideration of all of the design and operational requirements specified in this ROD, EPA finds that the Selected Remedy complies with the requirements of the 404(b)(1) Guidelines and is the least environmentally damaging practicable alternative that meets the project purpose and need. There are no practicable alternatives that avoid waters of the United States due to the location of the contaminated sediments. The Selected Remedy results in significantly less adverse impacts than the Preferred Alternative in the Proposed Plan because an on-site CDF will not be used to dispose of dredged material, therefore, 14 acres of aquatic environment will not be filled.

In many areas, remediated shallow areas would be backfilled to existing elevations and/or beach mix would be used to provide appropriate substrate. This would minimize impacts on aquatic resources and reduce or eliminate mitigation requirements. It was determined that only armored caps within shallow water areas and on river banks as well as river bank slopes will likely result in unavoidable impacts that will require compensatory mitigation resulting from implementation of the Selected Remedy. However, coordination with NMFS and USFWS will be done during remedy design and implementation to identify any further loss and mitigation requirements.

Avoidance and minimization measures and BMPs will be implemented throughout the remedial activities. In addition, avoidance and minimization measures would be implemented on Site to restore substrate, slope, and natural cover to the extent possible to maintain habitats and functions that would be altered during implementation. Compensatory mitigation would be required to replace lost habitats and functions such that there would be "no net loss" of aquatic resource functions.

The Selected Remedy will meet all of the substantive requirements of this ARAR during design, construction, and long-term monitoring. Controls required for construction activities to minimize the impacts include, but are not limited to:

- Water quality monitoring and substantive requirements of a contingency response plan to provide the necessary ARAR compliance documentation
- Changes in production rates
- Modification of work schedules
- Perform work during low river flows

- Use of surface booms or oil absorbent pads
- Decontamination of construction equipment prior to in-river use
- Prevent barge grounding
- Prevent incidental release of dredged or capping and residual management material during transloading
- Use of appropriate BMPs during transloading activities
- Storm water management at transloading facilities
- Appropriate location of staging of demolition and construction materials
- Meet substantive requirements of a Spill Prevention, Containment and Countermeasure (SPCC) Plan to provide the necessary ARAR compliance documentation
- Fish capture and removal inside work isolation areas
- Control and monitoring of dewatering activities and material
- Residual layer placement as soon as possible
- Use of physical barriers
- Placement of material from lower to higher elevations
- Monitoring for accurate placement of material
- Use of clean capping and residual management material
- Beach mix includes materials less than 2.5 inches
- Incorporation of vegetation on river bank caps, where possible

The Selected Remedy will be designed to avoid or minimize adverse impacts to aquatic resources and waters of the United States. Compensatory mitigation is considered only after other appropriate and practical options have been considered to avoid, minimize, or otherwise rectify unavoidable, adverse impacts on the aquatic environment, including impacts on aquatic species. It is assumed that 60 acres would require mitigation under the Selected Remedy. This compensatory mitigation entails the restoration, establishment, enhancement, and/or preservation of wetlands, streams, or other aquatic resources conducted specifically for the purpose of offsetting authorized impacts to these resources, on-Site wherever possible. A compensatory mitigation framework will be developed in coordination with NMFS and USFWS, which may use a Habitat Equivalency Analysis (HEA) method, Relative Habitat Value (RHV) scoring approach, or other approach to determine final compensatory mitigation acreages.

Additionally, ORS 196.825(5) and applicable substantive mitigation rules at OAR 141-085-510, 141-085-680, 141-085-0685, 141-085-0690, 141-085-0710, 141-085-715 require mitigation for expected adverse effects of removal and fill activities, thus substantive compliance with those requirements will be incorporated into the compensatory mitigation framework.

The substantive requirements of the CWA §401 and Oregon's Water Quality Law are also triggered due to the discharges of pollutants to surface water from dredging, capping, pulling pilings or other structure or debris removal activities required to implement the Selected Remedy. Both CWA §401 and Oregon's Water Quality Law require that any activity during the implementation of the remedial action that may result in a discharge to waters of the State requires reasonable assurance that water quality standards will be complied with and requires conditions and other requirements deemed necessary to be placed on the discharge.

During dredging, capping, pulling pilings, removal of structures or debris, and/or residual management material, potential short-term exceedances of some water quality criteria are likely. However, through the application of BMPs and engineering control measures water quality criteria are expected to be met in accordance with §401 and Oregon's Water Quality Law. Pertinent water quality-specific information will be considered during design and a water quality monitoring plan will be developed to document requirements to comply with these ARARs. Monitoring will be used to set conditions for the following activities (but not limited to) dredging speeds and techniques, establishing a point of compliance for water quality criteria, type and frequency of monitoring samples, and engineering controls. Monitoring will primarily seek to minimize sediment resuspension and dissolved chemical dispersion during dredging and capping activities, storm water management and treatment, and identify relevant, erosion control measures.

Additionally, §301 of the CWA prohibits a discharge of pollutants from a point source to waters of the U.S. unless such discharge is in compliance with §302, 306, 307, 318, 402, and/or 404 of the CWA, 33 U.S.C. §1311. Section 402 of the CWA, 33 U.S.C. §1342, provides substantive regulations regarding permitting point source discharges in compliance with the Act. CWA §301(b) requires all point sources to meet technology-based requirements. In addition, point sources must meet any water quality based effluent limit that is more stringent than the technology-based requirements, 33 U.S.C. § 1311(b). Where a waterbody is impaired for a specific pollutant and a TMDL has not been developed by the State and approved by EPA, a point source must meet water quality standards at the point of the discharge. §404 applies to return flows from all activities covered by that authority, such as return flow from barges or a transloading facility storing or transporting dredged material; however, excavation of river banks, if occurring from the uplands and not as a dredging activity and if more than one acre is disturbed cumulatively during any construction season, may invoke the need to, at a minimum, comply the substantive BMPs and other erosion control requirements of Oregon's construction stormwater NPDES general permit to control discharges of pollutants from such excavation and remediation activities. Likewise, an on-site transloading facility will need to apply relevant industrial stormwater controls. No other point source discharge is anticipated to be created by the Selected Remedy.

### *Rivers and Harbors Act*

The Rivers and Harbors Act is an applicable requirement and will guide development of institutional controls as well as construction of remedial actions in the navigation channel, to include placement of pilings or discharge of dredged material that may impair the flow or circulation of waters or reach of such waters. In general remedial actions taken or constructed in the navigation channel cannot interfere permanently with navigational capacity of the river. Contaminated sediments located in the navigation channel are assumed to be dredged and then a residuals management layer will be placed in the dredged area. The Willamette River currently has an authorized channel depth of -40 ft CRD. Prior to listing of the Portland Harbor Superfund Site on the NPL, the USACE proposed deepening the federally maintained navigation channel to -43 ft CRD.

Contamination at depths greater than the authorized depth of the navigation channel may be capped and those caps will be constructed below the authorized depth of dredging so as not to interfere with future dredging as well as to provide an overdredge allowance or buffer zone, as necessary, to protect the remedy from future dredge activities.

### *RCRA*

The substantive requirements of the RCRA ARAR will be met during design and implementation of the Selected Remedy. Analytical testing results of dredged material will be used for waste characterization and determinations of appropriate disposal. Data collected during remedial design will initially be used to inform the appropriate disposal site. A Materials Management Plan will provide the necessary ARAR compliance documentation. The Materials Management Plan will define record keeping requirements to document that RCRA substantive requirements are met, container requirements, storage requirements consistent with RCRA to be implemented during construction and operation of the waste handling facilities.

All dredged materials and contaminated river bank materials removed from the Site under the Selected Remedy will be managed under DMM Scenario 2 (off-site disposal facilities), with approximately 3,017,000 cy of contaminated sediment and 123,000 cy of soil sent to off-site disposal facilities. Ex-situ treatment is assumed for approximately 191,500 cy sediment and river bank soil. Treatment is assumed to be either low temperature thermal desorption or solidification/stabilization prior to disposal in a Subtitle C landfill. Dredged/excavated material will be tested to determine the appropriate disposal option and/or the need for treatment prior to disposal.

### *Oregon Hazardous Waste and Hazardous Materials*

OAR 340-093-0210 and 0220, State of Oregon solid waste general provisions regarding storage and collection of solid waste and transportation related requirements for trucks servicing a solid waste collection facility. Applicable requirements to operation of an on-site transloading facility for dredged materials slated for off-site disposal. The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy. State-listed hazardous waste has been identified offshore within SDU 7W. Hazardous waste generated during remedial actions may be treated and temporarily stored at transload facilities pending final transport and disposition. A Materials Management Plan will be developed as part of the design addressing how State treatment and storage regulations will be complied with during the construction and operation of the transload facilities. Under the Selected Remedy, it is assumed that 901,000 cy of dredged sediment (excluding sediment dredged from SDU 6W) may be managed as state-listed waste for disposal in a Subtitle D landfill without treatment.

### *Toxic Substances Control Act*

The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy. There are currently no sediment sample results that exceeded the TSCA threshold, so it is anticipated that very little, if any, waste will be generated that will require compliance with this ARAR. Any TSCA waste containing greater than 50 mg/kg of PCBs

generated as a result of remedial actions in the Site will meet requirements during transport and off-site disposal. The Chemical Waste Management Facility in Arlington, Oregon, is permitted to accept TSCA waste (RCRA and TSCA EPA ID Permit ORD089452353). The preparation of a Materials Management Plan during design and utilized during implementation will address proper handling and disposition of any TSCA waste generated during remedial actions.

#### *General Emissions Standards and Fugitive Emission Requirements*

The substantive requirements of these ARARs will be met during design and implementation of the Selected Remedy. Reasonable precaution to control fugitive emission of air contaminants will be taken in accordance with OAR 340-226. Emission of airborne particulate matter will be controlled to address OAR 340-208. Dust suppression will be maintained to eliminate air contaminant migration during remedial action in compliance with these ARARs. Air monitoring will be required to ensure that contaminants that volatilize will not exceed acceptable health based concentrations and adversely affect local communities and workers.

#### *Marine Mammal Protection Act*

The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy. The selected remedial actions will be carried out in a manner to avoid adversely affecting marine mammals (such as the Steller sea lion).

#### *Migratory Bird Treaty Act (MBTA)*

The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy. The selected remedial actions will be carried out in a manner to avoid adversely affecting migratory bird species, including individual birds or their nests (such as the Bald Eagle).

#### *Fish and Wildlife Coordination Act*

The substantive requirements of this ARAR will be met during design and implementation of the Selected Remedy. This statute and implementing regulations require coordination with federal and state agencies to ensure that any modification of any stream or other water body affected by any action authorized or funded by the federal agency provides adequate protection of fish and wildlife resources. Compliance with this ARAR will be met through the coordination with NMFS, USFWS, and ODFW on ESA, §404, and EFH compliance described above.

### **15.3. Cost Effectiveness**

The Selected Remedy represents a reasonable value in reducing risks at the Site and providing certainty that cleanup levels will be achieved for the costs to be incurred. In making this determination, the following definition was used: “A remedy shall be cost-effective if its costs are proportional to its overall effectiveness.” (40 CFR 300.430(f)(1)(ii)(D)). This determination was made evaluating three of the five balancing criteria in combination (long-term effectiveness and permanence; reduction in toxicity, mobility, and volume through treatment; and short-term effectiveness). Overall effectiveness is then compared to determine cost-effectiveness. The relationship of the overall effectiveness of the Selected Remedy was determined to be

proportional to its costs and hence the Selected Remedy represents a reasonable value for the money to be spent.)<sup>16</sup> The cost effectiveness summary of the remedy alternatives is presented in Table 29 in Appendix II.

It is important to note that more than one cleanup alternative can be cost-effective and the Superfund statute and implementing regulations do not mandate the selection of the most cost-effective cleanup alternative. In selecting among alternatives, EPA compared cost to overall effectiveness of each alternative individually and in relation to one another. Cost-effectiveness is concerned with the reasonableness of the relationship between the effectiveness afforded by each alternative and its costs compared to other available options.

As Alternative A (No Action) is not protective, it was not considered in the cost effectiveness evaluation. It is, however, included in Table 29 for reference. Alternative B is unable to achieve all chemical-specific ARARs, which is a threshold criterion. Although Alternatives B and D cost less and take less time to construct than the Selected Remedy, they do not address (treat or reliably contain) significant volumes of PTW and, therefore, are not considered cost effective relative to the other alternatives. All the other alternatives address the PTW either through treatment or containment and the remaining alternatives (I, E, F Mod, F, and G) progressively remove more contamination from the environment. However, Alternatives F and G, due to their larger footprints/volumes for capping, dredging, and ENR, will be, from a short-term effectiveness perspective, more disruptive to the habitat and the community with only relatively minor gains in risk reduction at significantly greater costs relative to Alternatives I, E, and F Mod. Therefore, EPA does not consider Alternatives F or G to be cost effective. EPA finds that Alternatives I, E, and F Mod to be cost-effective and reasonable given the relationship between the effectiveness afforded by each alternative and their costs compared to other options.

#### **15.4. Use of Permanent Solutions and Alternative Treatment Technologies**

EPA has determined that the Selected Remedy represents the maximum extent to which permanent solutions and treatment technologies can be utilized in a practicable manner at the Site. Of those alternatives that are protective of human health and the environment and comply with ARARs, EPA has determined that the Selected Remedy provides the best balance of trade-offs in terms of the five balancing criteria, while also considering the statutory preference for treatment as a principal element and State, tribe, and community acceptance.

The Selected Remedy permanently removes approximately 3,017,000 cy of contaminated sediment and 123,000 cy of contaminated river bank soil from the river system. Approximately 394 acres of river bottom and 23,300 lineal feet of river bank will be addressed through dredging or excavating contamination. Residuals from dredging and contaminated areas subject to ENR (approximately 28.2 acres) will be managed with a thin layer sand cover. Different caps

---

<sup>16</sup> It is important to note that cost effectiveness is not determined merely by plotting estimated costs of remedy alternatives against expected risk reduction. Rather as shown in Table 29 in Appendix II, a more robust assessment of three elements of overall effectiveness compared to overall costs is required. EPA has seen variations of such “knee of the curve” presentations and does not find these appropriate to evaluate cost effectiveness as they are not consistent with the NCP or EPA guidance.

(designed and constructed for appropriate contaminant containment) will be placed over approximately 176 acres of the Site.

The Selected Remedy will utilize a variety of cap configurations to contain contamination that remains in place. Where necessary, caps will be augmented with reactive and/or low permeability materials such as organoclay or activated carbon to provide a chemical isolation layer to reliably contain or treat wastes in place. In addition, routine monitoring of the caps (e.g., pore water and cleanup level monitoring) will be required to ensure their designed structure and function are maintained. After construction, and in combination with fish advisories and ICs, the remediated areas will no longer pose unacceptable risks to humans and the environment. Over time, cleanup levels will be achieved through MNR and there will be less reliance on ICs. Therefore, the Selected Remedy will provide adequate long-term control of risks to human health and the environment through eliminating and/or preventing exposure to the contaminated sediment and preventing movement of contaminated sediment.

The Selected Remedy is protective with respect to short-term risks. During construction, BMPs will be implemented to mitigate releases during cleanup and monitoring will be done in part to determine whether the BMPs are adequate or whether additional actions need to be taken.

Contaminated sediment that is to be dredged will be tested to determine the appropriate disposal location. If necessary, sediment will be dewatered and treated prior to disposal to ensure that contaminants are stabilized. Disposal in a regulated facility will ensure protection of human health and the environment since the wastes will be managed according to appropriate controls and regulations. Disposal in an off-Site facility is expected to be preferable to the community since most of the comments received during public comment rejected the on-Site CDF, as proposed in the Proposed Plan.

The Selected Remedy utilizes construction technologies (dredging, capping, ENR, MNR and ICs) that have been used at other sediment cleanup Sites across the country, as well as within Region 10, and it is, therefore, implementable. It is expected that the cleanup will occur over 13 years and although there will be impacts during construction in locations adjacent to the cleanup, these impacts are not expected to disrupt activities in a significant way. Based on experience from doing similar cleanup at other sites, arrangements can be made so that business, recreation, and other uses can continue during cleanup.

During tribal consultations, EPA learned that the tribes did not support the Proposed Plan alternative. Comments and input received during Tribal consultations reflected their concern about how much the Preferred Alternative in the Proposed Plan relied on MNR and they asked for more aggressive action to reduce risks at the Site with more permanent remedies. A significant number of comments received from the public during the public comment period mirrored the tribe's concerns. Since the Selected Remedy relies much less on MNR, it is expected that the tribes and public will be more supportive of this action.

### **15.5. Preference for Treatment as a Principal Element**

Although CERCLA §121(b) expresses a preference for selection of remedial actions that use permanent solutions and treatment technologies to the maximum extent practicable, there are situations that may limit the use of treatment, including when treatment technologies are not technically feasible or when the extraordinary size or complexity of a site makes implementation of treatment technologies impracticable. The Selected Remedy satisfies the statutory preference for treatment as a principal element of the remedy because treatment layers will be used in caps where necessary to adequately contain PTW. Additionally, excavated materials will be tested and treated prior to disposal as discussed in Section 14.2.9.2. Not all materials within the in-river portion of the Site will be treated because there is no cost-effective means of treating the large quantity of contamination present and it would not add any additional risk reduction for the Site. The NCP establishes the expectation that treatment will be used to address the principal threats posed by a site whenever practicable (40 CFR 300.430[a] [1] [iii] [A]). In general, principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be contained in a reliable manner, or will present a significant risk to human health or the environment should exposure occur. As discussed in Section 14, EPA has selected a remedy that will address all of the PTW through dredging and/or capping including the application of in-situ treatment amendments such as activated carbon where appropriate. In locations where NAPL or PTW that cannot be reliably contained will not be removed, significantly augmented caps will be placed. These caps will be designed to treat or sequester the NAPL or PTW, thereby reducing human health and ecological risk exposures to these source materials to acceptable levels.

### **15.6. Five-Year Review Requirements**

Since the Selected Remedy will leave contamination in place above levels that allow unlimited use and unrestricted exposure, as required by CERCLA, a statutory review will be conducted within five years after initiation of the remedial action to ensure that the remedy is, or will be, protective of human health and the environment. Five-year reviews are expected to be required as long as waste is left in place at the Site.

## 17. GLOSSARY

**Administrative Settlement and Order On Consent:** Legal vehicle to assure cleanup moves forward at a contaminated site. It typically contains stipulated penalties for non-performance by the liable entity and cannot be terminated unilaterally.

**Advection:** The transfer of heat or matter by the flow of a fluid, especially horizontally in the atmosphere or the sea.

**Anadromous fish:** Born in fresh water, spends most of its life in the sea and returns to fresh water to spawn. Salmon, smelt, shad, striped bass, and sturgeon are common examples.

**Anaerobic:** Relating to, involving, or requiring an absence of free oxygen.

**Applicable or Relevant and Appropriate Requirements (ARARs):** Applicable requirements are those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal environmental or State environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. Only those State standards that are identified by a state in a timely manner and that are more stringent than Federal requirements may be applicable. Relevant and appropriate requirements are those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal environmental or State environmental or facility siting laws that, while not "applicable" to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site. Only those State standards that are identified in a timely manner and are more stringent than Federal requirements may be relevant and appropriate.

**Aquablok™:** AquaBlok® is a patented, composite-aggregate technology resembling small stones and typically comprised of a dense aggregate (sand/gravel) core, clay or clay-sized materials, and polymers and commonly used in capping sediments.

**Armoring:** The practice of using material such as gravel or rocks to protect riverbanks or caps from erosion.

**Atmospheric deposition:** Gases and particulates released to the atmosphere from combustion sources such as motor vehicle emissions, slash burning (cutting and burning of plants), and industrial sources, contain nitrogen, sulphur, and metal compounds, which eventually settle to the ground as dust or fall to the earth in rain and snow.

**Background concentration:** The concentration of a substance in an environmental media (air, water or soil) that occurs naturally or is not the result of human activities.

**Bathymetry/bathymetric:** Study of underwater depth of lake or ocean floors. In other words, bathymetry is the underwater equivalent to topography.

**Beach mix:** A mix of sand, gravel and inorganic material used for anchoring caps to prevent erosion. This material mimicks previous habitat material.

**Bedload transport:** The particles in a flowing fluid (usually water) that are transported along the river bed.

**Benthic organisms/invertebrates:** Organisms that live in and on the bottom of the river floor. These organisms are known as benthos. Benthos include worms, clams, crabs, lobsters, sponges, and other tiny organisms that live in the bottom sediments.

**Best Management Practices (BMPs):** Methods determined to be the most effective, practical means of preventing or reducing pollution from nonpoint sources.

**Bioaccumulation:** The process through which the concentration of a chemical in an organism is greater than the concentration of the chemical in an ambient medium (usually water).

**Biological uptake:** The transfer of substances from the environment to plants, animals, and humans.

**Bioavailability:** A subcategory of absorption (one substance taken up by another) and is the fraction of an administered dose that reaches the blood circulation system, one of the principal pharmacokinetic properties of drugs. By definition, when a medication is administered intravenously, its bioavailability is 100%.

**Biodegradation:** The process by which organic substances are decomposed by micro-organisms (mainly aerobic bacteria) into simpler substances such as carbon dioxide, water and ammonia.

**Biota:** The animal and plant life of a particular region, habitat, or geological period.

**Bioturbation:** The disturbance of sedimentary deposits by living organisms.

**Cap amendments:** Material such as organoclay or activated carbon, added to caps to enhance performance in isolating and containing contaminants.

**Capital costs:** Expenditures required to construct each alternative, include all labor, equipment, and material costs associated with activities such as mobilization/demobilization; monitoring; site work; installation of dredging, containment, or treatment systems; and disposal.

**Carcinogens:** Any substance that can cause cancer.

**Cleanup:** Actions taken to address a release or threatened release of hazardous substances or pollutants and contaminants that may affect public health or the environment. Agencies often use the term broadly to describe various response actions or phases of remedial activities, such as an RI/FS. "Cleanup" is sometimes used interchangeably with the terms "remedial action," "remediation," "removal action," "response action" or "corrective action."

**Cleanup Level:** Residual concentration of a hazardous substance determined to be protective of public health, safety and welfare, and the environment under specified exposure conditions.

**Community Advisory Group (CAG):** A committee, task force or board of stakeholders affected by a Superfund or other hazardous waste site. A CAG provides a way for representatives of diverse community interests to present and discuss needs and concerns related to the site and the site cleanup process. CAGs are a community initiative and responsibility. They function independently of EPA.

**Community Involvement Plan (CIP):** A formal plan of communication and public participation activities developed by the EPA to ensure opportunities for community members to learn more about Superfund site activities and provide input to inform site decision-making. The plan is the result of information collected through community meetings and interviews and a review of site-related documents.

**Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA):** This law, enacted by Congress on December 11, 1980, created the Superfund program. Specifically, CERCLA: (1) established prohibitions and requirements concerning the assessment, investigation, and remediation of hazardous waste sites; (2) provided for liability of persons responsible for releases of hazardous waste at these sites; and (3) established a trust fund to provide for cleanup when no responsible party could be identified. CERCLA was amended by the Superfund Amendments and Reauthorization Act of 1986.

**Conceptual Site Model:** A written description and illustration of predicted relationships between receptors (both human and ecological) and the hazardous substances they may be exposed to.

**Contaminant of concern (COC):** Contaminants that pose an unacceptable risks to human health and the environment, as identified in the risk assessments.

**Contaminant of potential concern (COPC):** Contaminants identified in risk assessments that could cause risk.

**Desorption:** A phenomenon whereby a substance is released from or through a surface.

**Diffusion:** The process by which molecules intermingle as a result of their kinetic energy of random motion.

**Dioxin/furan:** By-products of chemical manufacturing, combustion (either in natural or industrial settings), metal processing and paper manufacturing that are highly persistent in the environment and toxic.

**Dredge residual:** Material that is left behind from dredging activities. This can occur from resuspension or from remaining contamination.

**Dynamic Equilibrium:** When contaminant concentrations in the sediment reach a steady state after remediation is conducted.

**Ecological Risk Assessment:** The process for evaluating how likely it is that the environment may be impacted because of exposure to one or more environmental stressors such as contaminants and hazardous substances.

**Ebullition:** The action of bubbling or boiling.

**Endangered Species Act (ESA):** Federal statute enacted in 1973 to conserve species and ecosystems. Species facing possible extinction are listed as “threatened” or “endangered” or as “candidate” species for such listings. Following such a listing, recovery and conservation plans are put in place to protect the species and its habitat.

**Enhanced Natural Recovery (ENR):** Accelerating the natural recovery process by adding a thin-layer cover of clean sand over contaminated sediment.

**Environment:** The sum of all external conditions affecting the life, development and survival of an organism.

**Environmental Protection Agency (EPA):** Federal agency whose mission is to protect human health and safeguard the environment.

**Environmental media:** Sediment, groundwater, surface water, and river banks.

**Erosion:** The action of surface processes (such as water flow or wind) that remove soil, rock, or dissolved material from one location on the Earth's crust, then transport it away to another location.

**Exposure pathway/route:** Means by which hazardous substances move through the environment from a source to a point of contact with people or animals.

**Ex-situ treatment:** The chemical, physical, biological, thermal, or electrical processes that remove, degrade, chemically modify, or stabilize contaminants after being removed from environmental media.

**Fate and Transport:** Natural transport of chemicals in ground water, surface water, soil, and atmosphere.

**Feasibility Study (FS):** An assessment of cleanup alternatives. A feasibility study, or FS, is conducted if the risk assessment performed during a remedial investigation establishes the presence of unacceptable risks. During an FS, EPA screens and evaluates alternatives to clean up a site based on nine evaluative criteria, including effectiveness, cost and community acceptance.

**Five-year review:** Pursuant to CERCLA a five-year review is required if the remedial action results in hazardous substances, pollutants or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure. This review evaluates whether such a remedy is protective of human health and the environment and is required no less often than every five years after the start of the cleanup.

**Focused COC:** A subset of the Site COCs with concentrations of the most widespread contaminants and those that pose the greatest risks. The focused COCs are used only for the development of SMAs and to develop RALs.

**Future Maintenance Dredge (FMD):** Areas near and around docks based on information regarding vessel activity, dock configuration, and future site uses where maintenance dredging is likely to occur. FMD locations were developed from estimates of likely future navigation depth requirements and potential future maintenance dredging depths near and around docks.

**Hazard Index (HI):** An estimate of the potential total non-cancer effects, derived by summing the HQ values.

**Hazard Quotient (HQ):** The ratio of the potential exposure to a substance and the level at which no adverse effects are expected. If the Hazard Quotient is calculated to be less than 1, then no adverse health effects are expected as a result of exposure.

**Hazardous Waste:** Solid wastes that possess at least one of four characteristics (ignitability, corrosivity, reactivity or toxicity), appear on special EPA lists, or are defined as hazardous by Oregon rules and statutes.

**Human Health Risk Assessment:** The process to estimate the nature and probability of adverse health effects in humans who may be exposed to chemicals in contaminated environmental media, now or in the future.

**In-situ treatment:** The chemical, physical, biological, thermal or electrical processes that remove, degrade, chemically modify or stabilize contaminants in place without any removal from environmental media.

**Institutional Control (IC):** Non-engineered instruments, such as administrative and legal controls, that help minimize the potential for human exposure to contamination and/or protect the integrity of the remedy. Although it is EPA's expectation that treatment or engineering controls will be used to address principal threat wastes and that groundwater will be returned to its beneficial use whenever practicable, ICs play an important role in site remedies because they reduce exposure to contamination by limiting land or resource use and guide human behavior at a site.

**In-river:** The proposed action will address contaminated sediment, river banks, groundwater, and surface water in a portion of the Portland Harbor Superfund Site. The upland portion will be addressed by DEQ.

**Migratory fish:** Fish that move from one part of a water body to another on a regular basis. Examples include spring Chinook salmon, lamprey, shad, and steelhead trout.

**Monitored Natural Recovery (MNR):** A risk reduction approach for contaminated sediment that uses ongoing, naturally occurring processes to contain, destroy, or reduce the bioavailability or toxicity of contaminants in sediment.

**Multnomah Channel:** The Multnomah Channel is a 21.5-mile (34.6 km) distributary of the Willamette River. It diverges from the main stem a few miles upstream of the main stem's confluence (RM 2.8) with the Columbia River in Multnomah County.

**Navigational Channel (NAV):** The area within the Site that is federally authorized. The US Army Corps of Engineers maintains the channel.

**National Contingency Plan (NCP):** The National Oil and Hazardous Substances Pollution Contingency Plan, commonly known as the National Contingency Plan, is the federal government's blueprint for responding to both oil spills and hazardous substance releases.

**National Priorities List (NPL):** EPA's list of the most serious uncontrolled or abandoned hazardous waste sites identified for possible long-term cleanup under Superfund. The list is

based primarily on the score a site receives from the Hazard Ranking System. EPA is required to update the NPL at least once a year.

**Nearshore:** Relating to or denoting the region of the river or riverbed relatively close to the shoreline

**Non aqueous phase liquid (NAPL):** Material that is not soluble in water.

**Non-carcinogen:** Hazardous substances with adverse health effects other than cancer on humans.

**Oregon Department of Environmental Quality (DEQ):** State agency whose job is to protect the quality of Oregon's Environment. DEQ is responsible for protecting and enhancing Oregon's water and air quality, for cleaning up spills and releases of hazardous materials, and for managing the proper disposal of hazardous and solid wastes.

**Organic contaminants:** Carbon-based chemicals, such as solvents and pesticides, which can get into water through runoff from facility discharge.

**Oxidation:** The loss of electrons or an increase in oxidation state by a molecule, atom, or ion.

**PCDD/F:** Polychlorinated dibenzodioxins and furans.

**Porewater:** The water occupying the spaces between sediment particles.

**Potentially Responsible Party (PRP):** An individual, company, government agency or other entity (such as owners, operators, transporters or generators of hazardous waste) potentially responsible for, or contributing to, contamination at a Superfund site. Whenever possible, the EPA requires a PRP, through administrative and legal actions, to clean up hazardous waste sites it has contaminated.

**Preliminary Assessment (PA):** An assessment of information about a site and its surrounding area. A preliminary assessment determines whether a site poses little or no threat to human health and the environment or if it does pose a threat, whether the threat requires further investigation.

**Preliminary Remediation Goal (PRG):** Used to develop the long-term contaminant concentration levels needed to be achieved to meet remedial action objectives by the remedial alternatives.

**Proposed Plan:** A plan for a site's cleanup that is available to the public for review and comment.

**Periodic costs:** These costs include activities that occur only once every few years (such as five-year reviews and equipment replacement) and site maintenance and monitoring.

**Present value costs:** The present value cost represents the amount of money that, if invested in the initial year of the remedial action at a given discount rate, would provide the funds required to make future payments to cover all costs associated with the remedial action over its planned life. The present value was calculated based on a 7% real discount rate as recommended in A

*Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 2000). Per guidance, inflation and depreciation are not considered in preparing the present value costs.

**Propwash:** The disturbed mass of air or water pushed aft by the propeller of an aircraft or propeller-driven watercraft.

**Public comment period:** A formal opportunity for community members and the public to review and contribute written comments on various EPA documents or actions.

**Public meeting:** Formal public sessions characterized by a presentation followed by a question-and-answer session. Formal public meetings may involve the use of a court reporter and the issuance of transcripts. Formal public meetings are required only for the Proposed Plan and ROD amendments at a site.

**Remedial Action Level (RAL):** RALs are a range of contaminant concentrations that are less than the current site-wide surface weighted average concentrations (SWACs) and greater than the PRGs or cleanup levels. At this Site, RALs are contaminant-specific sediment concentrations used to identify areas where capping and/or dredging will be assigned, and thus are the basis of the SMA boundaries or footprints.

**Remedial Action Objective (RAO):** Media-specific goals that remedial alternatives/remedy need to achieve for protecting human health and the environment.

**Resource Conservation and Recovery Act (RCRA):** Enacted in 1976, is the principal federal law in the United States governing the disposal of solid waste and hazardous waste.

*Subtitle C facility:* Landfills which are authorized under RCRA to accept hazardous waste for disposal.

*Subtitle D facility:* Municipal solid waste landfills and other solid waste disposal facilities.

**Record of Decision (ROD):** The document issued by EPA that documents site investigations, evaluation of human health and ecological risks, and evaluation of remedial alternatives. It describes the Selected Remedy to clean up a Superfund site.

**Release:** Any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping or disposing into the environment, including the abandonment or discarding of barrels, containers and other closed receptacles containing any hazardous substance, or any threat thereof, but excluding exposures within a workplace, emissions from the engine exhaust, nuclear material and the normal application of fertilizer.

**Remedial Alternative:** An action considered in the FS intended to reduce or eliminate unacceptable risks to human health and the environment at a site. The FS considers a range of remedial alternatives.

**Remedial Action:** The long term cleanup that can involve removal, containment or treatment of hazardous substances, pollutants or contaminants from land, water and air to protect human health and the environment. These actions are selected in RODs. Also see cleanup.

**Remedial Investigation (RI):** The first of the two-part site study known as a remedial investigation/feasibility study (RI/FS). The RI involves collecting and analyzing information about a site to determine the nature and extent of contamination.

**Removal Action:** Short-term immediate or emergency action that addresses releases of hazardous substances that require expedited responses. It may take place at any point in the site response process, and may include source control measures, removal of highly contaminated material, and/or posting warning signs or constructing fences around a contaminated site. These actions are identified in Removal Action Memos.

**Resident fish:** Fish species that complete their entire life cycle in the Site. Examples include small mouth bass, sculpin, and catfish.

**Residual layer:** Layer of material, generally sand, used to cover sediments disturbed by dredging or contaminated sediments left behind.

**Responsiveness Summary:** A component of the ROD that summarizes information about the comments and views of the public and support agency regarding both the remedial alternatives and general concerns about the site submitted during the public comment period. It also documents in the record how public comments were integrated into the decision-making process.

**Resuspension:** The renewed suspension of sediment, such as stirring up settled mud at the bottom of a body of water.

**Risk:** Probability that a hazardous substance, when released into the environment, will cause adverse effects in exposed humans or ecological receptors.

**Risk Assessment:** The process of evaluating whether a hazardous substance poses a potential threat to human health and the environment, either now or in the future.

**Scour:** The removal of bottom sediment by surface water movement/forces.

**Sediment:** Soils, sand, organic matter or minerals that accumulate on the bottom of a water body or an at some point in time are submerged.

*Surface sediment:* The top 30 cm of sediment.

*Subsurface sediment:* Sediment below surface sediment.

**Suspended Sediment:** Solid particles transported in a fluid media.

**Sediment Management Areas (SMAs):** Areas delineated by RALs where containment or removal technologies will be considered to immediately reduce risks upon implementation.

**Sediment Decision Units (SDUs):** A tool to evaluate the expected effectiveness of the alternatives throughout the site. Generally identified as areas with the highest focused COC concentrations over one river mile segment.

**Site Assessment:** Process to evaluate potential or confirmed releases of hazardous substances that may pose a threat to human health or the environment. Criteria established under the Hazard

Ranking System guide the process, which EPA, state, tribal or other federal agency environmental programs carry out.

**Solidification/stabilization:** To make into a solid, or to immobilize in a stable hard mass.

**Sorption:** A physical and chemical process by which one substance becomes attached to another.

**Source control:** Actions that prevent or reduce migration of contamination to environmental media, through removal, containment or treatment.

**Source material:** Material that includes or contains hazardous substances, pollutants, or contaminants that acts as a reservoir for migration of contamination to groundwater, surface water, sediment, or air or that acts as a source for direct exposure.

**Subsistence Fishers:** People who obtain a significant portion of their dietary protein from eating self-caught fish of various species.

**Superfund:** The program operated under the legislative authority of CERCLA that funds and carries out EPA solid waste emergency and long-term removal and remedial activities. These activities include establishing the National Priorities List, investigating sites for inclusion on the list, determining their priority, and conducting and/or supervising cleanup and other remedial actions. Superfund is the common name for CERCLA. People often use the term as an adjective for hazardous waste sites and the investigation and cleanup process directed by the EPA.

**Surface Weighted Average Concentrations (SWACs):** The concentration of a contaminant in sediment calculated as an average over a specified surface area.

**Thermal desorption:** An environmental remediation technology that utilizes heat to increase the volatility of contaminants such that they can be removed (separated) from the solid matrix (typically soil, sludge, or filter cake). Thermal desorption is not incineration.

**Transload Facility:** The facility where contaminated sediment is transferred from a barge to a land based transportation method, such as trucks or rail.

**Transition Zone Water (TZW):** The zone where surface water and groundwater mix.

**Uplands:** The portion of the Portland Harbor Superfund Site that includes the sources of contamination to the river, such as upland facilities. The upland portion is being addressed by DEQ.

**Volatilization:** Process where a liquid or solid is converted to a vapor.

**Willamette River:** The 187-mile long waterway in northwest Oregon that flows northward between the coast and the Cascade Mountains.

Focused contaminants of concern are shown in **bold**.

Abbreviations:

BEHP - bis(2-ethylhexyl)phthalate

BaP eq - benzo(a)pyrene equivalent

cPAH - carcinogenic polycyclic aromatic hydrocarbon

DDD - dichlorodiphenyldichloroethane

DDE - dichlorodiphenyldichloroethene

DDT - dichlorodiphenyltrichloroethane

DDx - DDD + DDE + DDT

HxCDF - 1,2,3,7,8,9-hexachlorodibenzofuran

max - maximum

mg/kg - milligram per kilogram

min - minimum

PAH - polycyclic aromatic hydrocarbon

PCB - polychlorinated biphenyl

PeCDD - pentachlorodibenzo-p-dioxin

PeCDF - pentachlorodibenzofuran

TCDD - 2,3,7,8-tetrachlorodibenzo-p-dioxin

TCDF - tetrachlorodibenzofurans

µg/kg - microgram per kilogram

**Table 2. Summary of Contaminants of Concern in Surface Water**

Contaminant	Units	Frequency of Detection	Minimum	Maximum	Mean	Median

Focused contaminants of concern are shown in **bold**.

Abbreviations:

- BaP eq - benzo(a)pyrene equivalent
- cPAH - carcinogenic polycyclic aromatic hydrocarbon
- DCE - dichloroethene
- DDD - dichlorodiphenyldichloroethane
- DDE - dichlorodiphenyldichloroethene
- DDT - dichlorodiphenyltrichloroethane
- DDx - DDD + DDE + DDT
- PAH - polycyclic aromatic hydrocarbon
- PCB - polychlorinated biphenyl
- PCE - tetrachloroethene
- PeCDD - pentachlorodibenzo-p-dioxin
- PeCDF - pentachlorodibenzofuran
- TCDD - 2,3,7,8-tetrachlorodibenzo-p-dioxin
- TPH - total petroleum hydrocarbon
- µg/L - microgram per liter

Table 4. Summary of Contaminants of Concern in Fish Tissue

Contaminant	Units	Fillet						Whole Body			
		Frequency of Detection	Minimum	Maximum	Min - Max	Mean	Median	Frequency of Detection	Min - Max	Mean	Median
Aldrin	µg/kg	15/53	0.005	0.119	0.005 - 0.119	0.05335	0.0541	47/141	0.00532 - 0.163	2.19	0.5

<b>PCBs</b>	µg/kg	7/13	9.8 - 154	46	25	27/35	6 - 1,020	336	156
<b>2,3,7,8-TCDD</b>	µg/kg	4/4	0.0006 - 0.0022	0.00148	0.00156	No results			
Tributyltin	µg/kg	13/38	3 - 240	40.00	10.5	8/20	0.97 - 16	6.0	2.9
Zinc	mg/kg	72/72	42 - 9,470	1,057	111	162/162	15 - 9,000	329	83

Focused contaminants of concern are shown in **bold**.

Abbreviations:

BEHP - bis(2-ethylhexyl)phthalate

DDD - dichlorodiphenyldichloroethane

DDE - dichlorodiphenyldichloroethene

DDT - dichlorodiphenyltrichloroethane

DDx - DDD + DDE + DDT

max - maximum

mg/kg - milligram per kilogram

min - minimum

PAH - polycyclic aromatic hydrocarbon

PCB - polychlorinated biphenyl

TCDD - 2,3,7,8-tetrachlorodibenzo-p-dioxin

µg/kg - microgram per kilogram

**Table 6. Concentrations of PTW Defined as “Highly Toxic”**

<b>Contaminant</b>	<b>Highly Toxic PTW Threshold (µg/kg) (10<sup>-3</sup> risk)</b>
PCBs	200
2,3,7,8-TCDD	0.01
2,3,7,8-TCDF	0.6
1,2,3,7,8-PeCDD	0.01
2,3,4,7,8-PeCDF	0.2
1,2,3,4,6,7,8-HxCDF	0.04
DDx	7,050
cPAHs (BaP eq)	106,000

Abbreviations:

cPAH (BaP eq) – carcinogenic PAHs (benzo(a)pyrene equivalent)

DDx – dichlorodiphenyldichloroethane + dichlorodiphenyldichloroethene +  
dichlorodiphenyltrichloroethane

HxCDF – hexachlorodibenzofuran

PAH – polycyclic aromatic hydrocarbon

PCB – polychlorinated biphenyl

PeCDD – pentachlorodibenzo-p-dioxin

PeCDF – pentachlorodibenzofuran

PTW – principal threat waste

TCDD – tetrachlorodibenzo-p-dioxin

TCDF – tetrachlorodibenzofuran

µg/kg – microgram per kilogram

**Table 7. Concentrations of PTW Defined as “Reliably Contained”**

<b>Contaminant</b>	<b>PTW Contaminants Reliably Contained</b>
Dioxins/furans	At all concentrations measured at the Site
PAHs	At all concentrations measured at the Site
Chlorobenzene	At concentrations <320 µg/kg
DDx	At all concentrations measured at the Site
Naphthalene	At concentrations <140,000 µg/kg
PCBs	At all concentrations measured at the Site

Abbreviations:

DDx – dichlorodiphenyldichloroethane + dichlorodiphenyldichloroethene +  
dichlorodiphenyltrichloroethane

PAH – polycyclic aromatic hydrocarbon

PCB – polychlorinated biphenyl

PTW – principal threat waste

µg/kg – microgram per kilogram

< – less than

**Table 8. Selected PCB and DDx Results for Fish Tissue**

<b>Fish Type</b>	<b>Number / Type of Sample</b>	<b>PCB Range (µg/kg)</b>	<b>DDx Range (µg/kg)</b>	<b>RM</b>
Smallmouth Bass	55 / Body without fillet	264 J to 8,160 J	43.1 J to 1,840	PCB: RM 11 to 12 DDx: RM 6 to 7
Brown Bullhead	6 / Whole body	83.3 J to 1,950 J	37.5 J to 141 J	RM 6 and 9
Black Crappie	4 / Whole body	103 J to 301 J	59.2 J to 99.6 J	RM 6 and 9
Carp	15 / Whole body	343 J to 25,100 J	73.3 J to 615 J	RM 4 to 8
Chinook Salmon	15 / Whole body	30 J to 277 J	16.9 J to 284	PCB: RM 3 and 4 DDx: RM 6 and 7
Sturgeon	5 / Skin-off fillets	84.7 to 964	38 J to 125 J	RM 6 and 7

Abbreviations:

DDx – total of dichlorodiphenyldichloroethane (DDD) + dichlorodiphenyldichloroethene (DDE) + dichlorodiphenyltrichloroethane (DDT)

J – estimated value

PCB – polychlorinated biphenyl

RM – river mile

µg/kg – microgram per kilogram

**Table 9. Fish Consumption Rates – Subsistence and Recreational Fishers**

<b>Receptor/Consumption</b>	<b>Subsistence Fisher RME</b>	<b>Recreational Fisher RME</b>	<b>Recreational Fisher CTE</b>
Adult	142 g/day	49 g/day	17.5 g/day
Child	60 g/day	20 g/day	7 g/day
Meals: Adult (8 ounces) Child (3 ounces)	19 meals/month	6.5 meals/month	2 meals/month

Abbreviations:

CTE – central tendency exposure

g – gram

RME – reasonable maximum exposure

**Table 10. Percentage of Types of Fish for Tribal Fishers Consumption**

<b>Species</b>	<b>Grams per day<sup>1</sup></b>	<b>Percent of diet</b>
Salmon	67	38.4
Lamprey	12.3	7.0
Sturgeon	8.6	4.9
Smelt	12.5	7.2
Whitefish	23.2	13.3
Trout	25.1	14.3
Walleye	9.9	5.7
Northern Pikeminnow	3.7	2.1
Sucker	7.3	4.2
Shad	5.2	3.0
<b>Total Consumption Rate</b>	<b>175</b>	<b>100</b>

(1) Rates are based on the weighted mean data in Table 18 of CRITFC 1994.

**Table 11a. BHHRA Results – Recreational and Subsistence Fishers**

Non-Cancer Hazard				Cancer Risk	
Recreational Fishers		Subsistence Fishers		Recreational Fishers	Subsistence Fishers
Child	Nursing Infant	Child	Nursing Infant	All Ages	All Ages
300	4,000	1,000	10,000	$4 \times 10^{-3}$	$1 \times 10^{-2}$

**Table 11b. BHHRA Results – Tribal Fishers (Fillet and Whole Body)**

Non-Cancer Hazard				Cancer Risk	
Fillet Only		Whole Body		Fillet Only	Whole Body
Child	Nursing Infant	Child	Nursing Infant	All Ages	All Ages
600	8,000	800	9,000	$2 \times 10^{-2}$	$1 \times 10^{-2}$

Abbreviations:

BHHRA – Baseline Human Health Risk Assessment

**Table 12. Number of COPCs Evaluated in the BERA**

<b>Medium or Diet</b>	<b>No. of COPCs</b>	<b>No. of Chemicals without Screening-Level TRVs</b>
Sediment	67	106
Invertebrate tissue	18	23
Fish tissue	16	8
Fish dietary dose	9	11
Bird dietary dose	23	19
Mammal dietary dose	12	11
Bird egg tissue	5	0
Surface water	14	19
TZW	58	14

**Notes:**

- BERA - baseline ecological risk assessment
- COPC - contaminant of potential concern
- TRV - toxicity reference value
- TZW - transition zone water

**Table 13. COPCs Forwarded to the BERA after Screening**

<b>Receptor Group</b>	<b>Media Evaluated</b>	<b>Number of COPCs</b>	<b>COPCs</b>
Benthic invertebrates, bivalves, decapods	Surface water, TZW, sediment, tissue	104	20 metals, 2 butyltins, 21 individual PAHs or PAH sums, 4 phthalates, 12 SVOCs, 6 phenols, 16 pesticide or pesticide sums, total PCBs, 2,3,7,8-TCDD (dioxin), 16 VOCs, 3 total TPH fractions, cyanide, perchlorate
Fish	Surface water, TZW, sediment, diet, tissue	74	19 metals, 4 butyltins, 17 individual PAHs or PAH sums, BEHP, 3 SVOCs, total PCBs, dioxin TEQ, total TEQ, 7 pesticide or pesticide sums, 18 VOCs, cyanide, perchlorate
Birds and mammals	Diet (birds and mammals), bird eggs	23 (birds) 12 (mammals)	11 metals, 3 individual PAHs or PAH sums, 2 phthalates, total PCBs, dioxin TEQ, PCB TEQ, total TEQ, 3 pesticide or pesticide sums
Aquatic plants, amphibians	Surface water, TZW	64	15 metals, monobutyltin, 16 individual PAHs, BEHP, 3 SVOCs, total PCBs, 6 pesticide or pesticide sums, 18 VOCs, gasoline-range hydrocarbons, cyanide, perchlorate

**Notes:**

- BEHP - bis(2-ethylhexyl) phthalate
- BERA - baseline ecological risk assessment
- COPC - contaminant of potential concern
- PAH - polycyclic aromatic hydrocarbon
- PCB - polychlorinated biphenyl
- SVOC - semivolatile organic compound
- TCDD - tetrachlorodibenzo-p-dioxin
- TEQ - toxic equivalent
- TPH - total petroleum hydrocarbons
- TZW - transition zone water
- VOC - volatile organic compound

**Table 14. COPCs with HQ  $\geq$  1.0 Organized by Assessment Endpoint and Line of Evidence for the Portland Harbor BERA**

Line of Evidence	COPCs with HQ $\geq$ 1.0
<b>Assessment Endpoint:<sup>a</sup> Benthic Invertebrate Survival, Growth, and Reproduction</b>	
<b>Macroinvertebrates (e.g., amphipods, isopods, bivalves, gastropods, oligochaetes, insects, decapods)</b>	
Survival and biomass of <i>Chironomus dilutus</i> and <i>Hyalella azteca</i> exposed to site sediments compared with reference area sediments	Responses based on chemical mixtures; no individual COPCs identified
Concentrations in site sediment compared with effect levels derived from FPM and LRM models (i.e., SQVs) predicting reduced survival or biomass based on Portland Harbor surface sediment concentrations and toxicity reported for both <i>Hyalella</i> and <i>Chironomus</i> endpoints	6 metals, TBT, 19 individual PAHs or group sums, dibutyl phthalate, 3 SVOCs, 2 phenolic compounds, PCBs, 15 individual pesticides or group sums, diesel-range hydrocarbons
Concentrations in site sediment compared with national consensus-based SQGs (PECs and related quotients), and effects-based SQGs (PELs, and related quotients)	8 metals, 14 individual PAHs or group sums, 2 PCBs, 9 individual pesticides or group sums
Concentrations in site sediment compared with TPH SQGs	Diesel-, gasoline-, residual-range hydrocarbons
Concentrations in surface water compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of benthic macroinvertebrate survival, growth, and reproduction	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP, total DDx, <sup>b</sup> ethylbenzene, trichlorethene
Concentrations in shallow TZW compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of benthic macroinvertebrate survival, growth, and reproduction	14 metals, 16 individual PAHs, 3 SVOCs, the pesticides 4,4'-DDT <sup>b</sup> and total DDx, <sup>b</sup> 16 VOCs, gasoline-range hydrocarbons, cyanide and perchlorate
Empirical (field-collected) whole-body concentrations of epibenthic organisms compared with tissue TRVs	None
Steady-state estimates of laboratory-exposed whole-body concentrations in <i>Lumbriculus</i> compared with tissue TRVs	Arsenic, copper, zinc, TBT, PCBs, total DDx
Predicted (BSAF) whole-body concentrations of <i>Lumbriculus</i> compared with tissue TRVs	TBT, PCBs, total DDX

**Table 14. COPCs with HQ ≥ 1.0 Organized by Assessment Endpoint and Line of Evidence for the Portland Harbor BERA**

Line of Evidence	COPCs with HQ ≥ 1.0
<b>Bivalves (clams, mussels)</b>	
Empirical (field-collected) whole-body concentrations in <i>Corbicula fluminea</i> and freshwater mussels compared with tissue TRVs	Copper, zinc, TBT, PCBs
Steady-state estimates of laboratory-exposed whole-body concentrations in <i>Corbicula fluminea</i> compared with tissue TRVs	TBT, BEHP, total DDx
Predicted (BSAF) whole-body concentrations in <i>Corbicula fluminea</i> compared with tissue TRVs	Total PCBs, total DDx
<i>Corbicula fluminea</i> survival compared with control data from bioaccumulation tests	Responses based on chemical mixtures; no individual COPCs identified
Survival and biomass of <i>Chironomus dilutus</i> and <i>Hyalella azteca</i> exposed to site sediments, compared with reference sediments	Responses based on chemical mixtures; no individual COPCs identified
Concentrations in surface water compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of benthic macroinvertebrate survival, growth, and reproduction	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP, total DDx, <sup>b</sup> ethylbenzene, trichlorethene
Concentrations in shallow TZW compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of benthic macroinvertebrate survival, growth, and reproduction	14 metals, 16 individual PAHs, 3 SVOCs, the pesticides 4,4'-DDT <sup>b</sup> and total DDx, <sup>b</sup> 16 VOCs, gasoline-range hydrocarbons, cyanide and perchlorate
Concentrations in site sediment compared with national consensus-based SQGs (PECs and related quotients) and effects-based SQGs (PELs and related quotients)	8 metals, 14 individual PAHs or group sums, 2 PCBs, 9 individual pesticides or group sums
Concentrations in site sediment compared with TPH SQGs	Diesel-, gasoline-, residual-range hydrocarbons
<b>Decapods (crayfish)<sup>c</sup></b>	
Empirical whole-body concentrations in crayfish compared with tissue TRVs	Copper
Predicted (BSAF or FWM) whole-body concentrations in crayfish compared with tissue TRVs	Total PCBs, total DDx

**Table 14. COPCs with HQ  $\geq$  1.0 Organized by Assessment Endpoint and Line of Evidence for the Portland Harbor BERA**

Line of Evidence	COPCs with HQ $\geq$ 1.0
Concentrations in site sediment compared with national consensus-based SQGs (PECs and related quotients) and effects-based SQGs (PELs and related quotients)	8 metals, 14 individual PAHs or group sums, 2 PCBs, 9 individual pesticides or group sums
Concentrations in site sediment compared with TPH SQGs	Diesel-, gasoline-, residual-range hydrocarbons
Concentrations in surface water compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of benthic macroinvertebrate survival, growth, and reproduction	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP, total DDx, <sup>b</sup> ethylbenzene, trichlorethene
Concentrations in shallow TZW compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of benthic macroinvertebrate survival, growth, and reproduction	14 metals, 16 individual PAHs, 3 SVOCs, the pesticides 4,4'-DDT <sup>b</sup> and total DDx, <sup>b</sup> 16 VOCs, gasoline-range hydrocarbons, cyanide and perchlorate
<b>Assessment Endpoint:<sup>a</sup> Fish Survival, Growth, and Reproduction</b>	
<b>Omnivorous Fish (white sturgeon, largescale sucker<sup>d</sup>)</b>	
Empirical whole-body concentrations compared with tissue TRVs	Total PCBs
Dietary dose (including incidental sediment ingestion) compared with dietary TRVs	Copper
Concentrations in surface water compared with state WQS, national AWQC, <sup>b</sup> or effects-based values derived from the literature that are protective of fish survival, growth, and reproduction	No COPCs had HQs $\geq$ 1.0 <sup>e</sup>
Correlation of lesion prevalence with areas of contamination and/or comparison to lesion-based TRVs (if relevant to receptor species) <sup>f</sup>	Inconclusive for PAHs
<b>Invertivorous Fish (juvenile Chinook salmon,<sup>g</sup> peamouth, sculpin)</b>	
Empirical whole-body concentrations compared with tissue TRVs	Copper, lead, total PCBs, total DDx, BEHP
Predicted (BSAF or FWM) whole-body concentration compared with tissue TRVs (sculpin only)	Total PCBs, total DDx

**Table 14. COPCs with HQ  $\geq$  1.0 Organized by Assessment Endpoint and Line of Evidence for the Portland Harbor BERA**

Line of Evidence	COPCs with HQ $\geq$ 1.0
Dietary dose (including incidental sediment ingestion) compared with dietary TRVs	Cadmium, copper, TBT
Concentrations in surface water compared with state WQS, national AWQC or effects-based TRVs reported in the literature	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP, total DDx <sup>b</sup> , trichlorethene
Concentrations in shallow TZW compared with state WQS, national AWQC or effects-based TRVs reported in the literature (sculpin only)	14 metals, 16 PAHs, 3 SVOCs, the pesticides 4,4'-DDT <sup>b</sup> and total DDx <sup>b</sup> , 16 VOCs, gasoline-range hydrocarbons, cyanide and perchlorate
<b>Piscivorous Fish (northern pikeminnow, smallmouth bass)</b>	
Empirical whole-body concentrations compared with tissue TRVs	Antimony, lead, total PCBs, total DDx, BEHP
Predicted (BSAF or FWM) whole-body concentrations compared with tissue TRVs (smallmouth bass only)	This LOE was not evaluated because empirical tissue data were available from all exposure areas.
Concentrations in surface water compared with reported state WQS, national AWQC, <sup>b</sup> or effects-based TRVs reported in the literature	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP
Dietary dose (including incidental sediment ingestion) compared with dietary TRVs	Copper
<b>Detritivorous Fish (Pacific lamprey ammocoete<sup>a</sup>)</b>	
Empirical whole-body concentration compared with tissue TRV	Copper
Concentrations in surface water compared with state WQS, national AWQC, or literature-based values that are protective of early life stages.	No COPCs had HQs $\geq$ 1.0 <sup>c</sup>
Concentration in shallow TZW compared with state WQS, national AWQC, or effects-based values reported in the literature that are protective of early life stages <sup>h</sup>	14 metals, 16 PAHs, 3 SVOCs, the pesticides 4,4'-DDT <sup>b</sup> and total DDx <sup>b</sup> , 16 VOCs, gasoline-range hydrocarbons, cyanide and perchlorate
<b>Assessment Endpoint:<sup>a</sup> Bird Survival, Growth, and Reproduction</b>	
<b>Invertivorous Birds (spotted sandpiper)</b>	
Dietary dose (including incidental sediment ingestion) compared with dietary TRV	Copper, benzo(a)pyrene, dibutyl phthalate, total PCBs, PCB TEQ, total dioxin/furan TEQ, total TEQ, sum DDE, total DDx, aldrin

**Table 14. COPCs with HQ ≥ 1.0 Organized by Assessment Endpoint and Line of Evidence for the Portland Harbor BERA**

Line of Evidence	COPCs with HQ ≥ 1.0
<b>Omnivorous Birds (hooded merganser)</b>	
Dietary dose (including incidental sediment ingestion) compared with dietary TRV	Total PCBs
<b>Piscivorous Birds (osprey, bald eagle)</b>	
Dietary-based approach incorporating food chain transfer of contaminants from appropriate fish species (assuming all exposure comes from prey fish) and incidental sediment ingestion	Lead, total PCBs
Measured concentrations in osprey eggs compared with egg- or embryo-based TRVs for DDT and metabolites, PCBs, and dioxin-like compounds	Total PCBs, PCB TEQ, total dioxin/furan TEQ, total TEQ
<b>Assessment Endpoint:<sup>a</sup> Mammal Survival, Growth, and Reproduction</b>	
<b>Aquatic-Dependent Mammals (mink, river otter)</b>	
Dietary dose compared with dietary TRVs	Aluminum, lead, total PCBs, PCB TEQ, total dioxin/furan TEQ, total TEQ
<b>Assessment Endpoint:<sup>a</sup> Amphibian Survival, Growth, and Reproduction (frogs, salamanders)</b>	
Concentrations in surface water compared with state WQS, national AWQC, or effects-based values reported in the literature that are protective of sensitive life stages	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP, total DDx <sup>b</sup>
Concentrations in shallow TZW compared with state WQS, national AWQC, or effects-based values reported in the literature that are protective of sensitive life stages	11 metals, 8 PAHs, the SVOC 1,2-dichlorobenzene, the pesticides 4,4'-DDT <sup>b</sup> and total DDx <sup>b</sup> , 8 VOCs, gasoline-range hydrocarbons, and the conventionals cyanide and perchlorate
<b>Assessment Endpoint:<sup>a</sup> Aquatic Plant Survival, Growth, and Reproduction (phytoplankton, periphyton, macrophytes)</b>	
Concentrations in surface water compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of sensitive life stages (e.g., germination, emergence, early life stage growth)	Zinc, benzo(a)anthracene, benzo(a)pyrene, naphthalene, BEHP, total DDx <sup>b</sup>

**Table 14. COPCs with HQ ≥ 1.0 Organized by Assessment Endpoint and Line of Evidence for the Portland Harbor BERA**

Line of Evidence	COPCs with HQ ≥ 1.0	
Concentrations in shallow TZW compared with state WQS, national AWQC, or effects-based values derived from the literature that are protective of sensitive life stages (e.g., germination, emergence, early life stage growth)	11 metals, 8 PAHs, the SVOC 1,2-dichlorobenzene, the pesticides 4,4'-DDT <sup>b</sup> and total DDx, <sup>b</sup> 8 VOCs, gasoline-range hydrocarbons, and the conventionals cyanide and perchlorate	
<p><sup>a</sup> The assessment endpoints for all receptors are based on protection and maintenance of their populations and the communities in which they live, except that the health of threatened or endangered species is to be protected at the level of the individual organism. Per the SOW and the problem formulation (Attachment 2), and as stated in the Programmatic Work Plan (Integral et al. 2004b), the assessment endpoints were expressed as the survival, growth, and reproduction of each receptor group.</p> <p><sup>b</sup> Risk estimates for total PCBs, 4,4'-DDT, and total DDx for the surface water and TZW LOEs are based on the alternative total PCB and 4,4'-DDT TRVs for the protection of directly exposed aquatic organisms, rather than the selected AWQC based TRVs. Additional exceedances occur using the AWQC-based TRVs and HQs, as presented in Table 11-3. The alternative TRVs are considered more appropriate for evaluating direct exposure of aquatic organisms because the national AWQC are based on protection of dietary risks to mammals and birds.</p> <p><sup>c</sup> Although these LOEs are components of the benthic invertebrate community, the bivalve population and decapod population assessment endpoints are presented separately in this table. Evaluation of sediment toxicity to <i>Chironomus</i> and <i>Hyalella</i> and comparison of surface water and shallow TZW concentrations to TRVs were each conducted and presented only once as part of the benthic invertebrate community assessment. Similarly, comparison of sediment concentrations to published SQGs also occurred and was presented only once as part of the benthic community assessment.</p> <p><sup>d</sup> Carp is not an ROC for the BERA but whole-body carp tissue was analyzed for dioxin-like chemicals, including PCB congeners; for these chemicals, carp is a surrogate for other omnivorous fish species.</p> <p><sup>e</sup> The site-wide total DDx surface water HQ was &gt; 1.0 based on the selected AWQC-based TRV but not the alternative TRV.</p> <p><sup>f</sup> Lesion prevalence is not a primary LOE in the BERA, inasmuch as it does not directly address any BERA assessment endpoint. Because effects on survival, growth, or reproduction cannot be quantified from the lesion LOE, no quantitative risk management recommendations can be derived from the lesion LOE.</p> <p><sup>g</sup> Juvenile Chinook salmon and Pacific lamprey ammocoetes were evaluated at the organism level because they have special status are (juvenile Chinook is federally threatened and Pacific lamprey is an Oregon state sensitive species of special concern to Tribes); effect thresholds based on reproduction are used as a surrogate for growth in juvenile Chinook salmon and Pacific lamprey ammocoetes.</p> <p><sup>h</sup> The TZW exposure pathway for fish receptors is considered complete and significant for only sculpin and lamprey ammocoetes. The ecological CSM shows a complete TZW exposure pathway for sucker, carp, and sturgeon but categorizes the pathway as insignificant.</p>		
<p>AWQC – ambient water quality criteria BEHP – bis(2-ethylhexyl) phthalate BERA – baseline ecological risk assessment BSAF – biota-sediment accumulation factor CERCLA – Comprehensive Environmental Response, Compensation, and Liability Act COPC – contaminant of potential concern CSM – conceptual site model DDD – dichlorodiphenyldichloroethane DDE – dichlorodiphenyldichloroethylene DDT – dichlorodiphenyltrichloroethane EPA – US Environmental Protection Agency</p>	<p>FWM – food web model HQ – hazard quotient LOE – line of evidence PAH – polycyclic aromatic hydrocarbon PCB – polychlorinated biphenyl PEC – probable effects concentration PEL – probable effects level ROC – receptor of concern SOW – scope of work SQG – sediment quality guideline SQV – sediment quality value</p>	<p>SVOC – semivolatile organic compound TBT – tributyltin TEQ – toxic equivalent total DDx – sum of all six DDT isomers (2,4'-DDD, 4,4'-DDD, 2,4'-DDE, 4,4'-DDE, 2,4'-DDT, and 4,4'-DDT) TPH – total petroleum hydrocarbons TRV – toxicity reference value TZW – transition zone water VOC – volatile organic compound WQS – water quality standards</p>

	Sculpin	Copper (1.7), total PCBs (9.4)

- <sup>a</sup> Sediment EFs are based on exceedances of PECs and PELs for metals, PAHs, PCBs, and pesticides, and based on sediment TRVs for petroleum hydrocarbons. All site-wide and bioassay samples were included in the assessment of sediment.
- <sup>b</sup> Two water TRVs exist for PCBs and DDxs in surface water. Max HQs based on AWQC are listed before max HQs based on the alternative TRV. See discussion in BERA Section 6.5.4 for the rationale for having two TRVs.
- <sup>c</sup> Value in parenthesis is the maximum hazard quotient for each contaminant within each RM segment of the Study Area.
- <sup>d</sup> Field collected clams and mussels.
- <sup>e</sup> Smallmouth bass tissue samples in the BERA dataset were often assigned as being collected from a RM range that does not fit with the RM ranges presented in this table. When a smallmouth bass tissue sample was available for a RM range that crosses over two RM ranges as defined in this table (e.g., a bass sample obtained from RM 6.5 to RM 7.5, which does not strictly correspond to RM 6 to RM 6.99 or RM 7 to RM 7.99 in this table), then the applicable tissue concentrations and resulting HQs are included in both RM ranges in this table (i.e. the sample/HQ is included in both RM 6 to RM 6.99 and RM 7 to RM 7.99).
- <sup>f</sup> Two water TRVs exist for 4,4'-DDT and total DDx in TZW. Max HQs based on AWQC are listed before max HQs based on the alternative TRV. See discussion in BERA Section 6.6.4 for the rationale for having two TRVs.
- <sup>g</sup> Sediment, surface water, bivalve (field clam/mussel) tissue, smallmouth bass tissue, and sculpin tissue samples collected in Swan Island Lagoon were not included in the other 1-mile RM ranges presented in this table. No TZW samples were collected in Swan Island Lagoon.

BEHP – bis(2-ethylhexyl) phthalate	PEC – probable effects concentration
COPC – chemical of potential concern	PEL – probable effects level
DDD – dichlorodiphenyldichloroethane	RM – river mile
DDE – dichlorodiphenyldichloroethylene	SVOC – semivolatle organic compound
DDT – dichlorodiphenyltrichloroethane	TBT – tributyltin
EF – exceedance factor	total DDx – sum of all six DDT isomers (2,4'-DDD, 4,4'-DDD, 2,4'-DDE, 4,4'-DDE, 2,4'-DDT and 4,4'-DDT)
HCH – hexachlorocyclohexane	TRV – toxicity reference value
HQ – hazard quotient	TZW – transition zone water
PAH – polycyclic aromatic hydrocarbon	VOC – volatile organic compound
PCB – polychlorinated biphenyl

<sup>a</sup> Several additional contaminants may also contribute to potentially unacceptable risk. These contaminants include ammonia and sulfide.

<sup>b</sup> In addition to ammonia and sulfide, the 22 COPCs identified solely as a result of predicted toxicity to benthic invertebrates (i.e., FPM and LRM results), the 5 chemicals with concentrations that exceeded only the PEC and/or PEL (i.e., not a COPC for any other benthic LOE), and residual-range hydrocarbons that exceeded only the TPH SQG are not included in this table.

BEHP – bis(2-ethylhexyl) phthalate	PAH – polycyclic aromatic hydrocarbon
COPC – chemical of potential concern	PCB – polychlorinated biphenyl
DDD – dichlorodiphenyldichloroethane	PEL – probable effects level
DDE – dichlorodiphenyldichloroethylene	SQG – sediment quality guideline
DDT – dichlorodiphenyltrichloroethane	TBT – tributyltin
FPM – floating percentile model	TEQ – toxic equivalent
HCH – hexachlorocyclohexane	TPH – total petroleum hydrocarbons
LOE – line of evidence	total DDx – sum of all six DDT isomers (2,4'-DDD, 4,4'-DDD, 2,4'-DDE, 4,4'-DDE, 2,4'-DDT, and 4,4'-DDT)
LRM – logistic regression model

Notes:

- (1) Surface Water Cleanup Levels - RAOs 3 and 7
- (2) Groundwater Cleanup Levels - RAOs 4 and 8
- (3) Sediment Cleanup Levels - RAOs 1 and 5
- (4) Fish Tissue Targets - RAOs 2 and 6
- (5) A/R indicates that the ARARs-based number and the risk-based number are the same.
- (6) The tissue target is a risk-based number and does not represent background levels. Additional data will be collected to determine background fish tissue concentrations for PCBs during design and construction of the Selected Remedy.
- (7) The cleanup level for cPAHs of 12 µg/kg is based on direct contact with sediment and is applicable to nearshore sediment. The cleanup level applicable to sediments in the navigation channel is 3,950 µg/kg and is based on human consumption of clams.

Abbreviations:

- A- ARAR-based number
- ARAR - applicable or relevant and appropriate requirement
- B - Background-based number
- BEHP - bis(2-ethylhexyl)phthalate
- BaP eq - benzo(a)pyrene equivalent
- C - carbon

**Table 17. Summary of Cleanup Levels or Targets by Media**

Abbreviations (continued):

Conc - concentration

cPAH - carcinogenic polycyclic aromatic hydrocarbon

DDD - dichlorodiphenyldichloroethane

DDE - dichlorodiphenyldichloroethene

DDT - dichlorodiphenyltrichloroethane

DDx - DDD + DDE + DDT

HxCDF - 1,2,3,7,8,9-hexachlorodibenzofuran

MCPP - 2-(4-chloro-2-methylphenoxy)propanoic acid

mg/kg - milligram per kilogram

PAH - polycyclic aromatic hydrocarbon

PBDE - polybrominated diphenyl ether

PCB - polychlorinated biphenyl

PeCDD - pentachlorodibenzo-p-dioxin

PeCDF - pentachlorodibenzofuran

R - risk-based number

RAO - remedial action objective

TCDD - 2,3,7,8-tetrachlorodibenzo-p-dioxin

TCDF - tetrachlorodibenzofurans

TPH - total petroleum hydrocarbons

µg/kg - microgram per kilogram

µg/L - microgram per liter

**Table 18. Summary of RALs for Focused COCs**

Focused COC	RAL (µg/kg)						
	Alt B	Alt C	Alt D	Alt E	Alt F	Alt G	Alt H

DDx	650	550	450	300	160	40	6.1

Abbreviations:

Alt – Alternative

COC – Contaminant of concern

DDx – dichlorodiphenyldichloroethane + dichlorodiphenyldichloroethene + dichlorodiphenyltrichloroethane

RAL – remedial action level

PAH – polycyclic aromatic hydrocarbon

PCB – polychlorinated biphenyl

PeCDD – pentachlorodibenzo-p-dioxin

PeCDF – pentachlorodibenzofuran

TCDD – tetrachlorodibenzo-p-dioxin

µg/kg – microgram per kilogram

**Table 19. RALs for Focused COCs – Alternative I**

Focused COC	RAL (µg/kg)				
	PTW	Alt B + PTW	Alt D	Alt E	Alt F
PCBs	200	200	500	200	75

1,2,3,7,8-PeCDD	0.01	0.003	0.0008	0.0008	0.0008
2,3,4,7,8-PeCDF	0.2	0.2	1	0.2	0.2
DDx	7,050	650	450	300	160

Abbreviations:

Alt – Alternative

COC – Contaminant of concern

DDx – dichlorodiphenyldichloroethane + dichlorodiphenyldichloroethene + dichlorodiphenyltrichloroethane

RAL – remedial action level

PAH – polycyclic aromatic hydrocarbon

PCB – polychlorinated biphenyl

PeCDD – pentachlorodibenzo-p-dioxin

PeCDF – pentachlorodibenzofuran

PTW – principal threat waste

TCDD – tetrachlorodibenzo-p-dioxin

µg/kg – microgram per kilogram

**Table 20. Summary of Acres Assigned to Each Technology**

Alternative	Technology						
	Cap	Dredge	Dredge/Cap	River Bank Excavation/Cap	In-Situ Treatment <sup>1</sup>	ENR	MNR
	(acres)	(acres)	(acres)	(lineal ft)	(acres)	(acres)	(acres)
B	22.8	66.6	5.5	9,633	6.7	99.8	1,966
C	30.2	80.2	6.4	11,047	5.0	97.4	1,948
D	44.8	121.1	10.9	13,887	3.2	87.0	1,900
E	65.6	188.3	15.3	18,231	0	59.8	1,838
F Modified	117.8	215.2	32.3	23,305	0	28.2	1,774
F	117.8	355.1	32.3	23,305	0	28.2	1,634
G	184.7	525.0	46.7	26,362	0	19.5	1,391
H	535.3	1,525.5	106.4	30,048	0	0	0
I	64.1	150.2	16.9	19,472	0	59.8	1,876

Note 1 – In-situ treatment quantity includes only those PTW areas outside of sediment management areas (SMAs) utilizing broadcast activated carbon. In-situ treatment within the SMAs is captured in cap and dredge/cap quantities.

Abbreviations:

ENR – engineered natural recovery

ft – feet

MNR – monitored natural recovery

**Table 21. Sediment RALs and PTW Thresholds for Selected Remedy**

Contaminants	Site Wide RALs <sup>(1)</sup>	PTW Thresholds <sup>(2)</sup>	Navigation Channel RALs
<b>Focused COCs</b>			
PCBs	75	200	1,000
Total PAHs <sup>(4)</sup>	13,000	NA	170,000
2,3,7,8-TCDD	0.0006	0.01	0.002
1,2,3,7,8-PeCDD	0.0008	0.01	0.003
2,3,4,7,8-PeCDF	0.2	0.2	1
DDx	160	7,050	650
<b>Additional Contaminants</b>			
2,3,7,8-TCDF	NA	0.6	NA
1,2,3,4,6,7,8-HxCDF	NA	0.04	NA
cPAHs (BaP Eq)	NA	106,000	NA
Chlorobenzene	NA	>320	NA
Naphthalene	NA	>140,000	NA

Notes:

1 – Site wide includes all areas of the Site except the navigation channel. FMD areas are subject to these RALs.

2 – PTW thresholds are based on highly toxic PTW values ( $10^{-3}$  risk) except chlorobenzene and naphthalene, which are threshold values for not reliably contained PTW.

Abbreviations:

BaP Eq – benzo(a)pyrene equivalent

cPAH –carcinogenic polycyclic aromatic hydrocarbon

COC – Contaminant of concern

DDx – dichlorodiphenyldichloroethane + dichlorodiphenyldichloroethene + dichlorodiphenyltrichloroethane

FMD – future maintenance dredge

HxCDF - hexachlorodibenzofuran

NA – not applicable

PAH – polycyclic aromatic hydrocarbon

PCB – polychlorinated biphenyl

PeCDD – pentachlorodibenzo-p-dioxin

PeCDF – pentachlorodibenzofuran

PTW – principal threat waste

RAL – remedial action level

TCDD – tetrachlorodibenzo-p-dioxin

TCDF – tetrachlorodibenzofuran

µg/kg – microgram per kilogram

> – greater than

<b>Summary of Alternative</b>	NO ACTION	Cap, dredge, in-situ treatment and enhanced natural recovery (ENR) of:  201 acres of sediments 9,633 lineal feet (lf) of river bank	Cap, dredge, in-situ treatment and ENR of:  267 acres of sediments 13,887 lf of river bank	Cap, dredge, and ENR of:  329 acres of sediment 18,231 lf of river bank	Cap, dredge, and ENR of:  394 acres of sediment 23,305 lf of river bank	Cap, dredge, and ENR of:  533 acres of sediments 23,305 lf of river bank	Cap, dredge, and ENR of:  776 acres of sediments 26,362 lf of river bank	Cap, dredging, and ENR of:  291 acres of sediments 19,472 lf of river bank
<b>River Banks Addressed (%) (RAO 9)</b>	0% - continued migration from river banks to sediment/surface water.	32% of river banks addressed	46% of river banks addressed	61% river banks addressed	78% river banks addressed	78% river banks addressed	88% river banks addressed	65% river banks addressed
<b>Benthic Areas Addressed (%) (RAO 5)<sup>2</sup> (IT: 50 % addressed)</b>	0% - No reduction in benthic risk	48% of benthic areas addressed	64% of benthic areas addressed	73% of benthic areas addressed	72% of benthic areas addressed	87% of benthic areas addressed	93% of benthic areas addressed	64% of benthic areas addressed
<b>Consumption of Prey (RAO 6) (IT: Eco HQ=10)</b>	No reduction in HQ.	Does not achieve IT  River mile (RM) scale: Maximum HQ = 19 (BEHP)  Sediment decision unit (SDU) scale: Maximum HQ=7 (BEHP)	Does not achieve IT  RM scale: Maximum HQ = 17 (BEHP)  SDU scale: Maximum HQ=5 (BEHP)	Does not achieve IT  RM scale: Maximum HQ = 15 (BEHP)  SDU scale: Maximum HQ=4 (BEHP)	Achieves IT for RM and SDU scale  RM Scale: Maximum HQ = 5 (BEHP)  SDU Scale: Maximum HQ = 3 (BEHP)	Achieves IT for RM and SDU scale  RM Scale: Maximum HQ = 5 (BEHP)  SDU Scale: Maximum HQ = 3 (BEHP)	Achieves IT for RM and SDU scale  RM Scale: Maximum HQ = 3 (BEHP)  SDU Scale: Maximum HQ = 1 (BEHP)	Does not achieve IT  RM scale: Maximum HQ = 19 (BEHP)  SDU scale: Maximum HQ=3 (BEHP)
<b>Direct Contact Surface Water (RAO 7)</b>	Exceedances of surface water cleanup levels would continue.	Not quantifiable. Time to achieve cleanup levels through monitored natural recovery (MNR) uncertain.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.
<b>COMPLIANCE WITH APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS (ARARs)</b>								
<b>Chemical-specific ARARs</b>	Would not meet water quality criteria (WQCs) and maximum contaminant levels (MCLs).	Would not be achieved	Complies	Complies	Complies	Complies	Complies	Complies
<b>Location-specific ARARs</b>	No location-specific ARARs	Complies. Addressed during design and implementation	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.	Same as Alternative B.
<b>Action-specific ARARs</b>	No action-specific ARARs	Complies. Addressed during design and implementation.  15 acres of mitigation	Same as Alternative B.  25 acres of mitigation	Same as Alternative B.  35 acres of mitigation	Same as Alternative B.  60 acres of mitigation	Same as Alternative B.  60 acres of mitigation	Same as Alternative B.  86 acres of mitigation	Same as Alternative B.  34 acres of mitigation
<b>LONG-TERM EFFECTIVENESS AND PERMANENCE</b>								

Table 22. Detailed Comparative Analysis of Remedial Alternatives

Expected Outcomes at Construction Completion	Alternative A	Alternative B	Alternative D	Alternative E	Alternative F Mod	Alternative F	Alternative G	Alternative I
<b>Summary of Alternative</b>	NO ACTION	Cap, dredge, in-situ treatment and enhanced natural recovery (ENR) of:  201 acres of sediments 9,633 lineal feet (lf) of river bank	Cap, dredge, in-situ treatment and ENR of:  267 acres of sediments 13,887 lf of river bank	Cap, dredge, and ENR of:  329 acres of sediment 18,231 lf of river bank	Cap, dredge, and ENR of:  394 acres of sediment 23,305 lf of river bank	Cap, dredge, and ENR of:  533 acres of sediments 23,305 lf of river bank	Cap, dredge, and ENR of:  776 acres of sediments 26,362 lf of river bank	Cap, dredging, and ENR of:  291 acres of sediments 19,472 lf of river bank
<b>Magnitude of Residual Risk (Post Construction [PC] Risk)</b>  <b>RAO 1</b>	Existing risk remains. Ability for natural recovery unlikely since in-river sources remain.	<u>Sediment:</u> Post Construction risk: 4.8x10 <sup>-5</sup>	<u>Sediment:</u> Post Construction risk: 2.2x10 <sup>-5</sup>	<u>Sediment:</u> Post Construction risk: 1.5x10 <sup>-5</sup>	<u>Sediment:</u> Post Construction risk: 1.0x10 <sup>-5</sup>	<u>Sediment:</u> Post Construction risk: 1.0x10 <sup>-5</sup>	<u>Sediment:</u> Post Construction risk: 7.2x10 <sup>-6</sup>	<u>Sediment:</u> Post Construction risk: 1.8x10 <sup>-5</sup>
<b>RAO 2 (Allowable Fish Meals at Construction Completion)</b>	Existing risk remains. Ability for natural recovery unlikely since in-river sources remain. OHA fish advisories would continue.	(see fish meal information under Overall Protectiveness)						
<b>RAO 3 - Direct Contact Surface Water (Risk at Construction Completion vs. Risk at Cleanup Level for each Contaminant of Concern [COC])</b>	Existing risk remains. Ability for natural recovery unlikely since in-river sources remain.	PCBs – 16 times > cleanup levels  TCDD TEQ – 13 times > cleanup level Carcinogenic polycyclic aromatic hydrocarbon (cPAH) – 2 times cleanup level	PCBs – 13 times > cleanup levels  TCDD TEQ – 11 times > cleanup levels	PCBs – 12 times > cleanup levels  TCDD TEQ – 8 times > cleanup levels	PCBs – 10 times > cleanup levels  TCDD TEQ – 7 times > cleanup levels	PCBs – 8 times > cleanup levels  TCDD TEQ – 7 times > cleanup levels	PCBs – 6 times > cleanup levels  TCDD TEQ – 5 times > cleanup levels	PCBs – 12 times > cleanup levels  TCDD TEQ – 9 times > cleanup level cPAH – 2 times cleanup level
<b>RAO 4 Migration Groundwater to Sediment/Surface Water (Contaminated Groundwater Plumes not Addressed)</b>	Existing risk remains. Ability for natural recovery unlikely since in-river sources remain.	84% not addressed.  The magnitude residual risk is uncertain because it is likely that not all contaminated pore water will be addressed.	77% not addressed.  Same as Alternative B	68% not addressed.  Same as Alternative B	61% not addressed  Same as Alternative B	54% not addressed.  Same as Alternative B	38% not addressed.  Same as Alternative B	67% not addressed.  Same as Alternative B
<b>RAO 5<sup>2</sup> Benthic Organisms (Benthic Areas not Addressed)</b>	Existing risk remains. Ability for natural recovery unlikely since in-river sources remain.	52% not addressed.  Degree of recovery is uncertain because it is likely that an insufficient amount of the benthic risk areas will be addressed.	36% not addressed.  Same as Alternative B	27% not addressed.  Same as Alternative B	28 % not addressed  Same as Alternative B	13% not addressed.  Same as Alternative B	7% not addressed.  Same as Alternative B	36% not addressed.  Same as Alternative B

Table 22. Detailed Comparative Analysis of Remedial Alternatives

Expected Outcomes at Construction Completion	Alternative A	Alternative B	Alternative D	Alternative E	Alternative F Mod	Alternative F	Alternative G	Alternative I

**Table 22. Detailed Comparative Analysis of Remedial Alternatives**

**Acronyms:**

AC – activated carbon  
COC – contaminant of concern  
DDE – dichlorodiphenyldichloroethane  
ENR – enhanced natural recovery  
HH – human health  
MCL – maximum contaminant limit  
PeCDF – pentachlorodibenzofuran  
RNA – regulated navigation area  
SMA – sediment management area  
yr – year

ARAR – applicable or relevant and appropriate  
cPAH – carcinogenic polycyclic aromatic hydrocarbon  
DDT – dichlorodiphenyltrichloroethane  
HQ – Hazard Quotient  
IC- institutional control  
MNR – monitored natural recovery  
PCB – polychlorinated biphenyl  
RAO – remedial action objective  
TCDD – tetrachlorodibenzo-p-dioxin  
% – percent

BEHP – bis(2-ethyl-hexyl)phthalate  
cy – cubic yard  
DMM - disposed material management  
H&S – health and safety  
IT – interim target  
O&M – operation and maintenance  
PC – post construction  
RM – river mile  
TCDF – tetrachlorodibenzofuran

BMP – best management practice  
DDD – Dichlorodiphenyldichloroethane  
eco – ecological  
HxCDF - hexachlorodibenzofuran  
lf – lineal feet  
OHA – Oregon Health Authority  
PTW – principal threat waste  
SDU – sediment decision unit  
TEQ – toxic equivalent concentration

**Notes:**

1 – Residual risk estimates are based on direct contact exposure to shallow sediments. There is insufficient data to estimate post construction risks based on exposure to beach sediments.

2 – Percentage is based on percentage of the Site that exceeds 10 times the benthic cleanup level.

3 – Allowable fish meals at completion represents the number of fish meals associated with a post-construction carcinogenic risk of  $1 \times 10^{-5}$  and an adult consumption rate based on a 142 g/day fish consumption rate and an 8 ounce fish meal. The child consumption rate based on a 60 g/day fish consumption rate and a 3.5 ounce fish meal.

**Table 23. Summary of Comparative Analysis for Remedial Alternatives**

Remedial Alternative	Description <sup>(1)</sup>	Threshold Criteria		Balancing Criteria				
		Overall Protection of Human Health and the Environment	Compliance with ARARs	Long-Term Effectiveness and Permanence	Reduction of Toxicity, Mobility, or Volume through Treatment	Short-Term Effectiveness	Implementability	Present Value Cost (Dollars)
A	No Action/No Further Action	—	—	NA	NA	NA	NA	NA
B	Dredge/Cap 95 acres; ENR 100 acres MNR 1,966 acres; In-situ 7 acres Ex-situ 191,573 cy; Disposal 627,652 cy	—	—	○	○	◐	●	\$
D	Dredge/Cap 177 acres; ENR 87 acres MNR 1,900 acres; In-situ 3 acres Ex-situ 191,573 cy; Disposal 1,181,238 cy	+	+	◑	◑	◑	◑	\$
E	Dredge/Cap 269 acres; ENR 60 acres MNR 1,838 acres; Ex-situ 191,573cy; Disposal 2,024,222 cy	+	+	◑	◑	◑	◑	\$\$
F Mod	Dredge/Cap 365 acres; ENR 28 acres MNR 1,774 acres; Ex-situ 191,573 cy; Disposal 3,017,189 cy	+	+	◑	◑	◑	◑	\$\$\$
F	Dredge/Cap 505 acres; ENR 28 acres MNR 1,634 acres; Ex-situ 191,573 cy; Disposal 4,585,401 cy	+	+	◑	◑	◑	◑	\$\$\$
G	Dredge/Cap 756 acres; ENR 19 acres MNR 1,391 acres; Ex-situ 191,573 cy; Disposal 7,396,598 cy	+	+	●	●	○	○	\$\$\$\$
I	Dredge/Cap 231 acres; ENR 60 acres MNR 1,876 acres; Ex-situ 191,573 cy; Disposal 1,752,374 cy	+	+	◑	◑	◑	◑	\$\$

**Table 23. Summary of Comparative Analysis for Remedial Alternatives**

**Legend for Qualitative Ratings System:**

Threshold Criteria	Balancing Criteria (Relative Performance of Criterion)	Balancing Criteria - Cost (Present Value Cost in Dollars)
- Unacceptable		
+ Acceptable	○ Least	\$ \$500M through \$750M
	◐ Low	\$\$ \$750M through \$1,000M
	◑ Moderate	\$\$\$ \$1,000M through \$1,500M
	◒ Better	\$\$\$\$ Greater than \$1,500M
	● Best	

**Note:**

(1) Disposal volume consists of total volume dredged (average of high and low volumes with overdredge) plus the river bank volume excavated

**Table 24. Description of Sediment Decision Units**

<b>SDU ID</b>	<b>Location</b>	<b>Description</b>	<b>Length (mile)</b>	<b>Acres</b>	<b>Focused COCs</b>

No SDU	RM 1.9-11.8	Any area not included in the other SDUs	9.9	1,309.4	Not defined by specific COCs

Abbreviations:

COC – Contaminant of concern

DDx – dichlorodiphenyldichloroethane + dichlorodiphenyldichloroethene + dichlorodiphenyltrichloroethane

E – east

Is. – Island

Nav – navigation

PAH – polycyclic aromatic hydrocarbon

PCB – polychlorinated biphenyl

PeCDD – pentachlorodibenzo-p-dioxin

PeCDF – pentachlorodibenzofuran

RM – river mile

SDU – sediment decision unit

TCDD – tetrachlorodibenzo-p-diox

W – west

Table 25a. Chemical-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Medium	Regulation/Citation	Criterion/Standard	Comments
Protection of surface water	Clean Water Act, 33 USC 1313 and 1314 (Sections 303 and 304). Most recent 304(a) list of recommended water quality criteria, as updated up to issuance of the ROD	Under CWA Section 304(a), EPA develops recommended water quality criteria for water quality programs established by states. Two kinds of water quality criteria are developed: one for protection of human health, and one for protection of aquatic life. CWA §303 requires States to develop water quality standards based on Federal water quality criteria to protect existing and attainable use or uses (e.g., recreation, public water supply) of the receiving waters.	The most recent 304(a) recommended water quality criteria are: (1) <b>Relevant and Appropriate</b> for cleanup standards for surface water and contaminated groundwater discharging to surface water if more stringent than promulgated state criteria; (2) <b>Relevant and Appropriate</b> as criterion to apply to limit short-term impacts from dredging and capping if more stringent than promulgated state criteria; and (3) <b>Relevant and Appropriate</b> as criterion to apply to point source discharges that may occur in implementing the remedy if more stringent than promulgated state criteria.
Protection of potential drinking water sources	Safe Drinking Water Act, 42 USC 300f, 40 CFR Part 141, Subpart O, App. A. 40 CFR Part 143	Establishes Maximum Contaminant Level Goals (MCLGs) and Maximum Contaminant Levels (MCLs) to protect human health from contaminants in drinking water.	<b>Relevant and Appropriate</b> as cleanup standards for groundwater and surface water at the Site, which are potential drinking water sources.
Protection of potential drinking water sources	EPA Regional Screening Level (RSL) for Groundwater. Office of Superfund Remediation and Technology Innovation, Assessment and Remediation Division. November 2015.	Establishes acceptable risk levels for individual contaminants to protect the human health drinking water use at the 1x10 <sup>-6</sup> level for individual carcinogens or hazard quotient (HQ) of 1. They are risk-based concentrations derived from standardized equations combining exposure information assumptions with EPA toxicity data.	<b>To Be Considered</b> criteria for cleanup standards for groundwater and surface water at the Site only for contaminants of concern for which there are no MCLGs or MCLs established because the groundwater and surface water are potential drinking water sources.
Measure of protectiveness of human health and the environment in all media	Oregon Environmental Cleanup Law ORS 465.315(b)(A). Oregon Hazardous Substance Remedial Action Rules OAR 340-122-0040(2)(a) and (c), 0115(2-4).	Sets standards for degree of cleanup required for hazardous substances. Establishes acceptable risk levels for human health at 1x10 <sup>-6</sup> for individual carcinogens, 1x10 <sup>-5</sup> for multiple carcinogens, and Hazard Index of 1 for noncarcinogens.	<b>Applicable</b> standards for the final selected remedy to achieve these human health carcinogen and noncarcinogen risk levels by implementation of dredging, capping, enhanced natural recovery, monitored natural recovery, off-site disposal, implementation of institutional controls and other response actions set forth in the ROD.
Protection of surface water	Water Pollution Control Act ORS 468B.048. State-wide Numeric water quality criteria set forth in OAR Part 340, Division 41, including, Toxic Substances criterion at OAR Part 340-41-0033 (Tables 30 and 40), and Designated Uses for the Willamette Basin and Numeric Water Quality Criteria specified for the Willamette Basin at OAR 340-041-340 and 340-041-0345	DEQ is authorized to administer and enforce CWA program in Oregon. The state has promulgated numeric water criteria, state-wide and specific Willamette Basin criteria, to protect Willamette Basin designated beneficial uses.	Oregon's numeric toxics water quality standards (Tables 30 and 40) are <b>Applicable</b> requirements as cleanup standards for surface water to the extent they are more stringent than Clean Water Act 304(a) recommended criterion. State promulgated numeric water quality criteria are <b>Applicable</b> standards for controls on discharges of pollutants to state waters that may violate such criteria during the implementation of remedial actions, such as setting limits on short-term impacts from dredging and capping, and limits on point source discharges that may occur in implementing the remedy. Oregon's promulgated numeric water quality criteria are <b>Relevant and Appropriate</b> as cleanup standards for contaminated groundwater discharging to surface water.

Table 25b. Action-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Action	Regulation/Citation	Criterion/Standard	Comments
Actions that discharge dredged or fill material into navigable waters	Clean Water Act, Section 404, 33 USC 1344 and Section 404(b)(1) Guidelines, 40 CFR Part 230 (Guidelines for Specification of Disposal Sites for Dredged or Fill Material)	CWA §404 regulates the discharge of dredged or fill material into waters of the U.S., including return flows from such activity. This program is implemented through regulations set forth in the 404(b)(1) guidelines, 40 CFR Part 230. The guidelines specify: the restrictions on discharge (40 CFR 230.10); the factual determinations that need to be made on short-term and long-term effects of a proposed discharge of dredged or fill material on the physical, chemical, and biological components of the aquatic environment (40 CFR 230.11) in light of Subparts C through F of the guidelines; and the findings of compliance on the restrictions (40 CFR 230.12). Subpart J of the guidelines provide the standards and criteria for the use of all types of compensatory mitigation when the response action will result in unavoidable impacts to the aquatic environment.	<b>Applicable</b> criteria and guidelines for evaluating impacts to the aquatic environment from dredging contaminated sediment, placement of capping material and enhanced monitored natural recovery material, and in-situ treatment of sediments that will occur in implementing the remedy. Through an initial Section 404 analysis with RI/FS information, it was determined that the remedy can be implemented in compliance with Section 404 requirements. However, more detailed remedial design information will be required to fully assess impacts and specify all of the requirements and controls that will need to be placed on dredging and placement of capping or other materials in the river, including return flows, and riverbank remediation, to minimize or avoid the impacts. Also through the 404 analysis in remedial design, exact amounts of compensatory mitigation for unavoidable loss of aquatic habitat will be determined and mitigation plans developed.
Actions that discharge pollutants to waters of U.S.	Clean Water Act, Section 402, 33 USC 1342	Regulates discharges of pollutants from point sources to waters of the U.S., and requires compliance with the standards, limitations and regulations promulgated per Sections 301, 304, 306, 307, 308 of the CWA. CWA §301(b) requires all direct dischargers to meet technology-based requirements. These requirements include, for conventional pollutants, application of the best conventional pollutant control technology (BCT), and for toxic and nonconventional pollutants, the best available technology economically achievable (BAT). Where effluent guidelines for a specific type of discharge do not exist, BCT/BAT technology-based treatment requirements are determined on a case-by-case basis using best professional judgment (BPJ). Once the BPJ determination is made, the numerical effluent discharge limits are derived by applying the levels of performance of a treatment technology to the wastewater discharge.	<b>Relevant and Appropriate</b> to remedial activities that result in a point source discharge of pollutants to the river if more stringent than state promulgated point source requirements.
Actions that discharge pollutants to waters of U.S.	Clean Water Act, 33 USC 1341, (Section 401), 40 CFR Section, 121.2(a)(3), (4) and (5) Also see OAR 340-048-0015 "When Certification Required" pursuant to Oregon state law.	Any federally authorized activity which may result in any discharge into navigable waters requires reasonable assurances that the activity will be conducted in a manner which will not violate applicable water quality standards by the imposition of any effluent limitations, other limitations, and monitoring requirements necessary to assure the discharge will comply with applicable provisions of sections 1311, 1312, 1313, 1316, and 1317 of the Clean Water Act. Oregon administrative rule OAR 340-048-0015, Provides that federally-approved activities that may result in a discharge to waters of the State requires evaluation whether an activity may proceed and meet water quality standards with conditions, which if met, will ensure that water quality standards are met.	<b>Relevant and Appropriate</b> CWA 401 requirement, if more stringent than state implementation regulations, that in-water response actions that result in a discharge of pollutants comply with water quality standards through the placement of water quality-based conditions and other requirements on the discharge deemed necessary. The <b>applicable</b> state regulations require reasonable assurance that any discharge to state waters will comply with state water quality standards. Actions to implement the remedial action that may result in discharges to state waters include, but may not be limited to, dredging, capping, placement of material for enhanced natural recovery, riverbank remediation, return flows or de-watering sediments. Conditions and other requirements deemed necessary so that state water quality standards are not violated will be placed on any such discharge.
Actions resulting in discharges to waters of the State of Oregon, including removal and fill activities	ORS 468B.025 and State water quality standards established by rule: OAR 340-041-0002 through 0059, and Willamette Basin Designated Uses and Basin-specific water quality standards at OAR 340-041-340 and OAR 340-041-345.	ORS 468B.025 prohibits pollution of any waters of the state and prohibits the discharge of any wastes into state waters if the discharge reduces the quality of the water below state water quality standards. By rule, the State establishes standards of quality and purity for the waters of the state	All state-wide and Willamette Basin-specific water quality standards, including numeric, narrative, and designated uses, are <b>Applicable</b> requirements for any discharges to surface water from point sources and remedial activities that may result in discharges to waters of the state, such as, dredge and fill, capping, placement of material for enhanced natural recovery, riverbank remediation, and return flows or de-watering sediments. State-wide and Willamette Basin-specific water quality standards are <b>Relevant and Appropriate</b> to measuring effectiveness of controls on contaminated groundwater discharging to surface water.
Actions resulting in discharges from removal and fill activities	ORS 196.825(5) -Statutory requirement to mitigate for expected adverse effects of removal and fill activities. Applicable substantive mitigation rules are: OAR 141-085-510, 141-085-680, 141-085 0685, 141-085-0690, 141-085-0710, 141-085-715.	State substantive requirements for mitigation for the reasonably expected adverse effects of removal or fill in a project development in waters of the state, including in designated Essential Indigenous Anadromous Salmonid Habitat.	<b>Applicable</b> compensatory mitigation standards and requirements for reasonably expected adverse effects, if any, from dredging, capping, placement of material for enhanced natural recovery, and riverbank remediation. The Site includes Essential Indigenous Anadromous Salmonid Habitat and the specifically-listed state regulations contain specific habitat mitigation standards not found in CWA Section 404 regulations for reasonably expected adverse effects of the dredging, capping and other remedial action activities, which will be incorporated into compensatory mitigation plans developed during remedial design.

Table 25b. Action-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Action	Regulation/Citation	Criterion/Standard	Comments
Actions in federal navigation channels	River and Harbors Act of 1899, Section 10, 33 USC Section 403 and implementing regulations at 33 CFR Sections 322(e), 323.3, 323.4(b)-(c) and 329	The creation of any obstruction not affirmatively authorized by Congress, to the navigable capacity of any of the waters of the United States is prohibited; and it shall not be lawful to build or commence the building of any wharf, pier, dolphin, boom, weir, breakwater, bulkhead, jetty, or other structures in any port, roadstead, haven, harbor, canal, navigable river, or other water of the United States, outside established harbor lines. 33 CFR 322(e) addresses placing of aids to navigation in navigable waters is under the purview of Section 10, and must meet requirements of the U.S. Coast Guard (33 CFR 330.5(a)(1)). 33 CFR Section 323.4(b) and (c) provide if any discharge of dredged or fill material contains any toxic pollutant listed under section 307 of the CWA such discharge shall require compliance with Section 404 of the CWA. Placement of pilings, or discharge of dredged material that where the flow or circulation of waters of the United States may be impaired or the reach of such waters reduced must comply with Section 10. 33 CFR 329.4 defines the terms "navigable water of the United States" for purposes of the USACE regulations, including those addressing the discharge of dredged or fill material.	<b>Applicable</b> requirement for how remedial actions are taken or constructed in the navigation channel so as not to create an obstruction to the navigable capacity. <b>Applicable</b> to the use of aids to navigation as institutional controls for maintaining the integrity of the selected remedy. <b>Applicable</b> to the placement of pilings or discharge of dredged material that may impair the flow or circulation of waters or reach of waters of the United States.
Actions generating pesticide residue	Hazardous Waste and Hazardous Materials II. Identification and Listing of Hazardous Waste OAR 340-101-0033(6) and (7); OAR 340-100-0010(j); and OAR 340-109-0010(3) and (4)	State regulations that identify and define pesticide residue as a state hazardous waste, but which are not subject to land disposal restrictions.	<b>Applicable</b> regulations for characterizing dredged material as a state hazardous waste for off-site disposal.
Actions handling PCB remediation wastes and PCB containing material	Toxic Substances Control Act, 15 USC §2601 et seq., 40 CFR Part 761, Subpart D and OAR 340-110-0065 (1) and (2)	TSCA Subpart D regulates storage and disposal of PCB wastes and establishes requirements for handling, storage, and disposal of PCB-containing materials, including PCB remediation wastes, and sets performance standards for disposal technologies for materials/wastes with concentrations in excess of 50 milligrams per kilogram (mg/kg). Establishes decontamination standards for PCB contaminated debris. Oregon PCB storage for disposal regulations require the owners or operators of any facility using containers described in CFR 761.65(c)(7)(i) prepare and implement a Spill Prevention Control and Countermeasure (SPCC) plan as described in 40 CFR Part 112. In complying with 40 CFR Part 112, the owner or operator shall read "oil(s)" as "PCB(s)" whenever it appears. Because the remedy requires removal of sediment to specific depths and the maximum PCB concentrations detected in areas of the river to be dredged do not exceed 50 mg/kg, no substantive requirements triggered. If additional testing during remedial design identifies sediments at concentrations of 50 mg/kg PCBs, TSCA regulations may be applicable for managing dredged material for off-site disposal and listed here: 40 CFR 761.1(b)(5), 40 CFR 761.3, 40 CFR 761.50(a) and (b)3, 40 CFR 761.61(a)(5) and (b), 40 CFR 761.65(c)(9)(i)-(iii), and 40 CFR 761(c).	TSCA decontamination and disposal requirements are <b>Applicable</b> to the disposal of contaminated dredged material, debris, or surface water with PCB contamination if dredged sediment is found to contain 50 mg/kg in concentration. Based on current data, PCB concentrations in dredged sediment at or above 50 mg/kg are not expected, but if found, the cleanup will comport with this standard. Certain types of debris that may be encountered and which appears to be PCB equipment or potentially from a PCB Containing source, will require sampling and analysis compliant with TSCA to determine if it is PCB remediation waste and needs to be disposed as such.
Risk-based limits protective of human health for air emissions associated with soil or sediment removal	Clean Air Act, 40 CFR Parts 50 and 52	Places restrictions on air emissions from stationary and mobile sources that creates threats to human health as defined in the regulations and which may be generated from equipment used to construct the remedy.	These regulations are <b>Relevant and Appropriate</b> to evaluating how emissions may be minimized or reduced during construction of the remedy.
Actions generating air emissions	Oregon Air Pollution Control ORS 468A et seq., General Emissions Standards OAR 340-226	DEQ is authorized to administer and enforce Clean Air program in Oregon. Rules provide general emission standards for fugitive emissions of air contaminants and require highest and best practicable treatment or control of such emissions.	<b>Applicable</b> to remedial actions taking place on-site on upland properties. Could apply to earth-moving equipment, dust from vehicle traffic, and mobile-source exhaust, among other things.

Table 25b. Action-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Action	Regulation/Citation	Criterion/Standard	Comments
Actions that involve handling of dredged sediment or riverbank soils containing asbestos	National Emission Standards for Asbestos, 40 CFR 61.150(a)(1)(i) - (v)	40 CFR 61.150(a) requires that there be no visible emissions to the outside air during collection, processing, packaging, or transporting of any asbestos-containing waste material. Subsections (a)(1)(i) and (ii) require that asbestos-containing waste material be adequately kept wet and provide how to keep such wet so as not to discharge any visible emissions to the outside air. Subsection (a)(1)(iii) requires that after wetting, seal all asbestos-containing waste material in leak-tight containers while wet; or, for materials that will not fit into containers without additional breaking, put materials into leak-tight wrapping. Subsections (a)(1)(iv) and (v) require: Label the containers or wrapped materials specified in paragraph (a)(1)(iii) of this section using warning labels specified by Occupational Safety and Health Standards of the Department of Labor, Occupational Safety and Health Administration (OSHA) under 29 CFR 1910.1001(j)(4) or 1926.1101(k)(8). The labels shall be printed in letters of sufficient size and contrast so as to be readily visible and legible. For asbestos-containing waste material to be transported off the facility site, label containers or wrapped materials with the name of the waste generator and the location at which the waste was generated.	<b>Relevant and Appropriate</b> as standards for handling dredged sediment or riverbank soils containing asbestos that is going to on-site or off-site disposal facilities. Friable asbestos may be encountered during remediation in riverbanks and in the river where landfilling or disposal of friable asbestos occurred at industrial operations using such material, such as, chemical manufacturers and ship building and dismantling operations, and where encountered the cleanup will comport with this standard.
Actions that involve off-site disposal of dredged sediment or riverbank soils containing asbestos	National Emission Standards for Asbestos, 40 CFR 61.150(b)(1) and (2) and (c)	40 CFR 61.150(b)(1) and (2) require: All asbestos-containing waste material shall be deposited as soon as is practical by the waste generator at a waste disposal site operated in accordance with the provisions of § 61.154, or an EPA-approved site that converts RACM and asbestos-containing waste material into nonasbestos (asbestos-free) material according to the provisions of § 61.155. Subsection (c) requires: Mark vehicles used to transport asbestos-containing waste material during the loading and unloading of waste so that the signs are visible. The markings must conform to the requirements of §§ 61.149(d)(1) (i), (ii), and (iii).	<b>Applicable</b> to offsite transportation, treatment and disposal of asbestos-containing waste material segregated from contaminated environmental media such as sediment and soil that is generated during dredging or excavation of sediment and riverbank soils.
Actions on the riverbanks that expose and manage on-site soils containing asbestos	National Emission Standards for Asbestos, 40 CFR 61.151(a)(2) and (3), 40 CFR 61.151(b)(1)(i) through (iii) and 40 CFR 61.151(b)(2)	40 CFR 61.151(a)(2) requires: Cover the asbestos-containing waste material with at least 15 centimeters (6 inches) of compacted nonasbestos-containing material, and grow and maintain a cover of vegetation on the area adequate to prevent exposure of the asbestos-containing waste material. In desert areas where vegetation would be difficult to maintain, at least 8 additional centimeters (3 inches) of well-graded, nonasbestos crushed rock may be placed on top of the final cover instead of vegetation and maintained to prevent emissions. 40 CFR 61.151(b)(3) requires: Cover the asbestos-containing waste material with at least 60 centimeters (2 feet) of compacted nonasbestos-containing material, and maintain it to prevent exposure of the asbestos-containing waste. 40 CFR 61.151(b)(1)(i) through (iii) requires: (1) Display warning signs at all entrances and at intervals of 100 m (328 ft) or less along the property line of the site or along the perimeter of the sections of the site where asbestos-containing waste material was deposited. The warning signs must: (i) Be posted in such a manner and location that a person can easily read the legend; and (ii) Conform to the requirements for 51 cm x 36 cm (20" x 14") upright format signs specified in 29 CFR 1910.145(d)(4) and this paragraph; and (iii) Display the following legend in the lower panel with letter sizes and styles of a visibility at least equal to those specified in this paragraph. Spacing between any two lines must be at least equal to the height of the upper of the two lines.  40 CFR 61.151(b)(2) requires: Fence the perimeter of the site in a manner adequate to deter access by the general public.	<b>Applicable</b> to exposed asbestos-containing waste material and soils managed in situ on riverbanks during remediation or taken off-site for disposal.
Actions generating air emissions	Fugitive Emission Requirements OAR 340-208-0205, 0208, and 0209	State regulations that prohibit any person from openly accumulating asbestos material or asbestos-containing material and sets disposal requirements for Friable Asbestos and Nonfriable Asbestos	<b>Applicable</b> to remedial actions that may encounter friable or nonfriable asbestos material or asbestos-containing material and the off-site disposal of such.

Table 25b. Action-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Action	Regulation/Citation	Criterion/Standard	Comments
Actions that may alter waterbodies and that may effect fish and wildlife	Fish and Wildlife Coordination Act. 16 USC 662 and 663, 50 CFR 6.302(g)	Requires federal agencies to consider effects on fish and wildlife from projects that may alter a body of water and mitigate or compensate for project-related losses, which includes discharges of pollutants to water bodies.	<b>Applicable</b> to determining impacts and appropriate mitigation, if necessary, for effects on fish and wildlife from filling activities or discharges from point sources.
Actions that may affect ESA listed and State protected fish and wildlife species	ODFW Fish Management Plans for the Willamette River. OAR 635, div 500	Provides basis for in-water work (dredging and filling) windows in the Willamette River.	<b>Applicable</b> to placing restrictions on when dredging and filling can occur in the Willamette River due to presence of ESA listed and state protected species at the site.
Actions that may affect marine mammals	Marine Mammal Protection Act. 16 USC §1361 et seq. 50 CFR 216	Imposes restrictions on the taking, possession, transportation, selling, offering for sale, and importing of marine mammals.	<b>Applicable</b> to response actions that could harm marine mammals in the Willamette River and may require best management practices be used for observing and avoiding contact with such species during construction of the remedy.
Actions that may affect migratory birds	Migratory Bird Treaty Act. 16 USC §703 50 CFR §10.12	Makes it unlawful to take any migratory bird. "Take" is defined as pursuing, hunting, wounding, killing, capturing, trapping and collecting.	<b>Applicable</b> to response actions that could harm migratory birds using the Willamette River and may require use of best management practices for observing and avoiding contact with such species during construction of the remedy.
On-site actions that involve generating, handling and disposal of hazardous waste	OAR 340-100-0001(3) and OAR 340-100-0002(1)	Oregon has adopted and incorporates by reference the federal RCRA hazardous waste management program. Oregon adopted the federal Hazardous Waste Identification Rule that provides for an exclusion for dredged materials subject to the requirements of a permit under the Clean Water Act or the Marine Protection, Research, and Sanctuaries Act from RCRA Subtitle C.	Oregon's hazardous waste and materials regulations are <b>Applicable</b> to the generation, storage, handling, treatment and disposal of hazardous waste on-site and slated for off-site disposal. Oregon's hazardous waste identification rule exempts handling and on-site management of dredged materials subject to the requirements of a permit under the Clean Water Act or Marine Protection, Research, and Sanctuaries Act. However, any dredged material that will be disposed of in an off-site disposal facility must comply with these standards.
Actions generating solid wastes or hazardous wastes for off-site disposal	Solid waste defined in 40 CFR 261.2. Determining if solid waste is hazardous per 40 CFR § 262.11(a-c) and OAR 340-102-0011 - Hazardous Waste Determination	Must determine if solid waste (residue as defined in OAR 340-100-0010) is a hazardous waste using the following method: <ul style="list-style-type: none"> <li>• Should first determine if waste is excluded from regulation under 40 CFR261.4; and</li> <li>• Must then determine if waste is listed as a hazardous waste under subpart D 40 CFR part 261 or whether the waste is (characteristic waste) identified in subpart C of 40 CFR part 261 by either: <ul style="list-style-type: none"> <li>(1) Testing the waste according to the methods set forth in subpart C of 40 CFR part 261, or according to an equivalent method approved by the Administrator under 40 CFR §260.21; or</li> <li>(2) Applying knowledge of the hazard characteristic of the waste in light of the materials or the processes used. Additionally, Oregon has promulgated its own hazardous waste determination regulation: "(1) The provisions of this rule replace the requirements of 40 C.F.R. Sec. 262.11.</li> </ul> </li> </ul> (2) A person who generates a residue as defined in OAR 340-100-0010 must determine if that residue is a hazardous waste using the following method: (a) Persons should first determine if the waste is excluded from regulation under 40 C.F.R. Sec. 261.4 or OAR 340-101-0004; (b) Persons must then determine if the waste is listed as a hazardous waste in Subpart D of 40 C.F.R. Part 261; (c) Persons must then determine if the waste is listed under the following listings: NOTE: Even if the waste is listed, the person still has an opportunity under OAR 340-100-0022 to demonstrate to the Commission that the waste from their particular facility or operation is not a hazardous waste. (d) Regardless of whether a hazardous waste is listed through application of subsections (2)(b) or (2)(c) of this rule, persons must also determine whether the waste is hazardous under Subpart C of 40 C.F.R. Part 261 by either: (A) Testing the waste according to the methods set forth in Subpart C of 40 C.F.R. Part 261, or according to an equivalent method the Department approves under OAR 340-100-0021, or NOTE: In most instances, the Department will not consider approving a test method until the EPA approves it. (B) Applying knowledge of the hazard characteristic of the waste in light of the materials or the processes used."	Hazardous waste characterization and determination is <b>Applicable</b> for off-site disposal.
Actions generating dredged material hazardous waste	40 CFR § 261.4(g)	Dredged material that is subject to the requirements of Section 404 of the CWA is not a hazardous waste for purposes of regulation under RCRA.	The exemption is <b>Applicable</b> to the dredging, in-situ treatment, handling, storage or other on-site activities of dredged materials that are being managed in accordance with Section 404 analysis and approvals.

Table 25b. Action-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Action	Regulation/Citation	Criterion/Standard	Comments
Actions generating RCRA hazardous waste that will be disposed of in a permitted off-site disposal facility	40 CFR § 264.13(a)(1)	Must obtain a detailed chemical and physical analysis on a representative sample of the waste(s), which at a minimum contains all the information that must be known to treat, store, or dispose of the waste in accordance with pertinent sections of 40 CFR 264 and 268.	This requirement is <b>Applicable</b> to characterizing dredged materials for off-site disposal.
Actions generating RCRA hazardous waste	40 CFR § 268.7(a)(1)	Must determine if the hazardous waste has to be treated before land disposed. This is done by determining if the waste meets the treatment standards in 40 CFR 268.40, 268.45, or 268.49 by testing in accordance with prescribed methods or use of generator knowledge of waste. This determination can be made concurrently with the hazardous waste determination required in 40 CFR 262.11. Must comply with the special requirements of 40 CFR § 268.9 in addition to any applicable requirements in 40 CFR § 268.7.	This requirement is <b>Applicable</b> to characterizing and treating dredged materials slated for off-site disposal.
Actions generating RCRA hazardous waste	40 CFR § 268.9(a)	Must determine each EPA Hazardous Waste Number (waste code) applicable to the waste in order to determine the applicable treatment standards under 40 CFR 268 et seq. This determination may be made concurrently with the hazardous waste determination required in Sec. 262.11 of this chapter. Must determine the underlying hazardous constituents [as defined in 40 CFR 268.2(i)] in the characteristic waste.	This requirement is <b>Applicable</b> to characterizing and treating dredged materials slated for off-site disposal.
Actions generating industrial wastewater	40 CFR § 261.4(a)(2)	Industrial wastewater discharges that are point source discharges subject to regulation under section 402 of the CWA, as amended, are not solid wastes for the purpose of hazardous waste management. [Comment: This exclusion applies only to the actual point source discharge. It does not exclude industrial wastewaters while they are being collected, stored or treated before discharge, nor does it exclude sludges that are generated by industrial wastewater treatment.]	This requirement is <b>Applicable</b> to wastewater generated by the remedy that will be discharged from a point source in accordance with Section 402 of the CWA.
Actions requiring temporary storage of hazardous waste	OAR 340-102-0034 40 CFR § 262.34(a); 40 CFR §262.34(a)(1)(i); 40 CFR § 262.34(a)(2) and (3) 40 CFR § 262.34(c)(1)	A generator may accumulate hazardous waste at the facility provided that (accumulation of RCRA hazardous waste on site as defined in 40 CFR §260.10) :  <ul style="list-style-type: none"> <li>• waste is placed in containers that comply with 40 CFR 265.171–173; and</li> <li>• the date upon which accumulation begins is clearly marked and visible for inspection on each container;</li> <li>• container is marked with the words “hazardous waste”; or</li> <li>• container may be marked with other words that identify the contents if accumulation of 55 gal. or less of RCRA hazardous waste or one quart of acutely hazardous waste listed in §261.33(e) at or near any point of generation</li> </ul> <p style="text-align: right;">Oregon</p> <p>hazardous waste regulations further require:  (1) In addition to the requirements of 40 CFR 262.34, a generator may accumulate hazardous waste on-site for 90 days or less without a permit provided that, if storing in excess of 100 containers, the waste is placed in a storage unit that meets the Accumulation requirements of 40 CFR 264.175 and  (2) A generator shall comply with provisions found in 40 CFR, Part 262 and each applicable requirement of 40 CFR 262.34(a), (b), (c), (d), (e), and (f).</p>	The substantive requirements are <b>Applicable</b> to temporary storage of hazardous waste at an on-site transloading facility, but no permit will be required.
Actions resulting in the storage of solid waste	OAR 340-093-0210 and 0220	State of Oregon solid waste general provisions regarding storage and collection of solid waste and transportation related requirements for trucks servicing a solid waste collection facility.	Applicable requirements to operation of an on-site transloading facility for dredged materials slated for off-site disposal.
Actions resulting in the storage of solid waste	OAR 340-095-0010, 0020, 0030, 0050(1) & (2), 0070(2)	State of Oregon solid waste regulations for solid waste land disposal sites other than municipal solid waste landfills. Specifically, regulations related to the location siting, operating criteria, design criteria, groundwater monitoring and closure requirements for a non-municipal solid waste landfill.	<b>Applicable</b> requirements to the siting, design, operation and closure of an on-site transloading facility for dredged material slated for off-site disposal.

Table 25b. Action-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site

Action	Regulation/Citation	Criterion/Standard	Comments
Actions transporting hazardous materials	49 CFR 171.1(b)	Any person who, under contract with a department or agency of the federal government, transports "in commerce," or causes to be transported or shipped, a hazardous material shall be subject to and must comply with all applicable provisions of the HMTA and HMR at 49 CFR 171 - 180 related to marking, labeling, placarding, packaging, emergency response, etc.	<b>Applicable</b> to transportation of hazardous materials.
Actions that involve storage and treatment of hazardous waste at the transloading facility	40 CFR Part 264, Subparts B, C, F, G, I, J, K, L, M, AA, BB, CC, and DD	These regulations provide standards for location, design, operation, and closure of units in which treatment of hazardous waste may occur at the transloading facility. These regulations also provide requirements for use and management of containers, tank systems, surface impoundments, waste piles, and land treatment units one or more of which may be used for the storage and treatment of hazardous waste at the transloading facility. Subparts AA, BB, and CC provide air emission standards for process vents, equipment leaks, and tanks, surface impoundments and containers may be used at the transloading facility.	The listed requirements of Part 264 are <b>Applicable</b> to the siting, design, operation, and closure of any containers, tank systems, surface impoundments, waste piles or land treatment areas used for the storage (over 90 days) and/or treatment of hazardous waste on-site prior to disposal off-site. The specific storage system and treatment methods that may be employed at the on-site transloading facility will be determined during remedial design.

**Table 25c. Location-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site**

Location	Regulation/Citation	Criterion/Standard	Comments
Presence of archaeologically or historically sensitive area	Native American Graves Protection and Reparation Act, 25 USC 3001-3013, 43 CFR 10	Requires Federal agencies and museums which have possession of or control over Native American cultural items (including human remains, associated and unassociated funerary items, sacred objects and objects of cultural patrimony) to compile an inventory of such items. Prescribes when such Federal agencies and museums must return Native American cultural items. "Museums" are defined as any institution or State or local government agency that receives Federal funds and has possession of, or control over, Native American cultural items.	If Native American cultural items are present on property belonging to the Oregon Division of State Lands (DSL) that is a part of the response action area, this requirement is <b>Applicable</b> . If Native American cultural items are collected by an entity which is either a federal agency or museum, then the requirements of the law are <b>Applicable</b> .
Presence of archaeologically or historically sensitive area	Indian Graves and Protected Objects ORS 97.740-760	Prohibits willful removal of cairn, burial, human remains, funerary object, sacred object or object of cultural patrimony. Provides for re-interment of human remains or funerary objects under the supervision of the appropriate Indian tribe. Proposed excavation by a professional archaeologist of a native Indian cairn or burial requires written notification to the State Historic Preservation Officer and prior written consent of the appropriate Indian tribe. Prohibits persons from excavating, injuring, destroying or damaging archaeological sites or objects on public or private lands unless authorized.	<b>Relevant and Appropriate</b> if archaeological material is encountered.
Presence of archaeologically or historically sensitive area	Archaeological Objects and Sites ORS 358.905- 955 ORS 390.235	Imposes conditions for excavation or removal of archaeological or historical materials.	<b>Relevant and appropriate</b> if archaeological material encountered.
Presence of archaeologically or historically sensitive area	National Historic Preservation Act. 16 USC 470 et seq. 36 CFR Part 800	Requires the identification of historic properties potentially affected by the agency undertaking, and assessment of the effects on the historic property and seek ways to avoid, minimize or mitigate such effects. Historic property is any district, site, building, structure, or object included in or eligible for the National Register of Historic Places, including artifacts, records, and material remains related to such a property.	<b>Applicable</b> if historic properties are potentially affected by remedial activities.
Presence of archaeologically or historically sensitive area	Archaeological and Historic Preservation Act. 16 USC 469a-1	Provides for the preservation of historical and archaeological data that may be irreparably lost as a result of a federally-approved project and mandates only preservation of the data.	<b>Applicable</b> if historical and archaeological data may be irreparably lost by implementation of the remedial activities.
Presence of floodplain as designated on FEMA Flood Insurance map	44 CFR 60.3(d)(2) and (3)	Prohibits encroachments that would result in any increase in flood levels during occurrence of base flood discharge.	FEMA flood rise requirements are considered <b>Relevant and Appropriate</b> requirements for remedial actions that involve capping or other placement of material in the river or on riverbanks that may increase flood levels.

**Table 25c. Location-Specific ARARs for Remedial Action at the Portland Harbor Superfund Site**

Location	Regulation/Citation	Criterion/Standard	Comments
Presence of floodplain as designated on map	Federal Emergency Management Act regulations at 44 CFR 9 (which sets forth the policy, procedure and responsibilities to implement and enforce Executive Orders 11988 (Management of Floodplain) <b>To Be Considered</b> , as amended by E.O. 13690 and 11990 (Protection of Wetlands) <b>To Be Considered</b>	44 CFR 9 (Requirements for Flood Plain Management Regulations Areas) Requires measures to reduce the risk of flood loss, minimize impact of floods, and restore and preserve the natural and beneficial values of floodplains. The Executive Orders 11988 as amended by 13690 direct federal agencies to evaluate the potential effects of action that may be taken in a floodplain and to avoid, to the extent possible, long-term and short-term adverse effects associated with the occupancy and modification of floodplains, and to avoid direct or indirect support of floodplain development wherever there is a practicable alternative. Executive Order 11990 directs that activities conducted by federal agencies avoid, to the extent possible, long-term and short-term adverse effects associated with the modification or destruction of wetlands and to avoid direct or indirect support of new construction in wetlands when there are practicable alternatives.	The substantive identified FEMA regulations are <b>Relevant and Appropriate</b> for assessing impacts, if any, to the floodplain and flood storage from the response action and developing compensatory mitigation that is beneficial to floodplain values. Substantive portions of the Executive Order are <b>To-Be-Considered</b> .
Presence of wetlands	Executive Order for Wetlands Protection. Executive Order 11990 (1977) <b>To Be Considered</b>	Requires measures to avoid adversely impacting wetlands whenever possible, minimize wetland destruction, and preserve the value of wetlands.	<b>To Be Considered</b> guidelines in assessing impacts to wetlands, if any, from the response action and for developing appropriate compensatory mitigation for the project.
Presence of state-listed threatened or endangered wildlife species	Protection and Conservation Programs ORS. 496.171 to 496.182. Survival Guidelines OAR 635-100-0135	Survival Guidelines are rules for state agency actions affecting species listed under Oregon's Threatened or Endangered Wildlife Species law.	Substantive requirements of Survival Guidelines are <b>Relevant and Appropriate</b> to remedial activities affecting state-listed species.
Presence of essential fish habitat	Magnuson-Stevens Fishery Conservation and Management Act. 50 CFR Part.600.920	Requires federal agencies consult with NMFS on actions that may adversely affect Essential Fish Habitat (EFH), defined as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity."	<b>Applicable</b> because the National Marine Fisheries Service has designated the Lower Willamette River as EFH. EPA evaluated effects to EFH from the proposed remedial action in a biological assessment.
Presence of federally endangered or threatened species	Endangered Species Act. 16 USC 1536 (a)(2), Listing of endangered or threatened species per 50 CFR 17.11 and 17.12 or designation of critical habitat of such species listed in 50 CFR 17.95	Actions authorized, funded, or carried out by federal agencies may not jeopardize the continued existence of endangered or threatened species or result in the adverse modification of species' critical habitat. Agencies are to avoid jeopardy or take appropriate mitigation measures to avoid jeopardy.	<b>Applicable</b> to remedial actions that may impact endangered or threatened species or critical habitat that are present at the site. Listed species are found at the Site, and critical habitat for listed salmonids has been designated within the site. Coordination will occur with the National Marine Fisheries Service and US Fish and Wildlife Service regarding actions to be taken, their impacts on listed species, and measures that will be taken to reduce, minimize, or avoid such impacts so as not to jeopardize the continued existence or adversely modify critical habitat. If take cannot be avoided, take permission from the Services will be obtained. EPA evaluated effects to listed and threatened species and critical habitat from the proposed remedial action in a preliminary biological assessment. As further details are developed in remedial design, the biological assessment will be supplemented.

**Table 26. Summary of Remedial Alternative Costs**

<b>Alternative</b>	<b>Disposal Scenario</b>	<b>Capital Cost</b>	<b>Periodic Cost</b>	<b>Present Value Cost</b>	<b>Construction Duration</b>
A	NA	\$0	\$0	\$0	0
B	DMM 2	\$352,097,000	\$290,324,000	\$451,460,000	4 years

<b>TOTALS:</b>	<b>\$1,184,607,000</b>	<b>\$524,028,000</b>	<b>\$1,708,635,000</b>		<b>\$1,054,204,802</b>
<b>TOTAL PRESENT VALUE OF SELECTED REMEDY <sup>4</sup></b>					<b>\$1,054,200,000</b>

**Notes:**

<sup>1</sup> The Selected Remedy is expected to require cost expenditures for perpetuity since some contamination addressed by the remedy within the sediment bed and associated riverbank soils would remain in-place that do not allow for unrestricted use or unlimited exposure to human or ecological receptors. However, the period of analysis was assumed to be 30 yrs beyond the start of construction in Year 0.

<sup>2</sup> Total annual expenditure is the total cost per year with no discounting.

<sup>3</sup> Present value cost by year is the total annual expenditure discounted by a factor for that year representing the 7.0% real discount rate recommended by "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study", EPA 2000.

<sup>4</sup> Total present value is rounded to the nearest \$10,000. Inflation and depreciation are excluded from the present value cost.

Costs presented for the selected remedy are expected to have an accuracy between -30% to +50% of actual costs, based on the scope presented.

Percentages used for contingency and professional/technical services costs are based on guidance from Section 5.0 of "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study", EPA 2000. Modifications to the percentages applied for contingency and professional/technical services are documented in Appendix IV.

**Abbreviations:**

AC	Acre
CY	Cubic Yard
LS	Lump Sum
QTY	Quantity
SF	Square Foot
TON	Ton

**Table 29. Summary of Cost Effectiveness**

Alternative (check box if cost-effective) <sup>1</sup>	Present Value Cost	Incremental Cost <sup>2</sup>	Long-Term Effectiveness and Permanence	Reduction of Toxicity, Mobility and Volume Through Treatment	Short-Term Effectiveness
			because it is likely that not all contaminated river banks will be addressed with this alternative. <ul style="list-style-type: none"> <li>Adequacy and reliability of controls is dependent on the same proven and reliable technologies; however, there is an incremental increase in capped areas (additional 81.2 acres) and an incremental decrease in MNR (less 243 acres).</li> </ul>		
<p><b>COST-EFFECTIVENESS SUMMARY:</b></p> <ul style="list-style-type: none"> <li>Alternatives A, B, D, F, and G are not considered to be cost-effective.</li> <li>Alternatives I, E, and F Mod are considered to cost-effective as defined in 40 CFR 300.430(f)(1)(ii)(D).</li> </ul>					

If – linear feet  
 cy – cubic yards  
 HI – hazard index  
 PTW – principal threat waste  
 ENR – enhanced natural recovery  
 H&S – health and safety  
 BMPs – best management practices  
 TCDD – Tetrachlorodibenzo-p-dioxin  
 TEQ – Toxic Equivalent Concentration  
 cPAH – Carcinogenic polycycli29c aromatic hydrocarbons

SMA – sediment management areas  
 RM – river mile  
 PC – post construction  
 TCDF – Tetrachlorodibenzofuran  
 PeCDF – Pentachlorodibenzofuran  
 HxCDF – Hexachlorodibenzofuran  
 MNR – monitored natural recovery  
 O&M – operation and maintenance  
 ICs – Institutional Controls  
 RNAs – regulated navigation areas

**Notes:**

- 1 – The alternatives are presented in order of increasing present value cost.
- 2 – Incremental cost is the difference in present value cost from the previous alternative.
- 3 – Residual risk estimates are based on direct contact exposure to shallow sediments. There is insufficient data to estimate post construction risks based on exposure to beach sediments.
- 4 – Allowable fish meals at completion represents the number of fish meals associated with a post-construction carcinogenic risk of  $1 \times 10^{-5}$  and an adult consumption rate based on a 142 g/day fish consumption rate and an 8 ounce fish meal. The child consumption rate based on a 60 g/day fish consumption rate and a 3.5 ounce fish meal.
- 5 – Percentage is based on percentage of the Site that exceeds 10 times the benthic cleanup level.
- 6 – In-situ treatment includes areas within and outside of SMAs.

**Table 2-9**  
**Occurrence, Distribution, and Selection of Chemicals of Potential Concern - Industrial Use Beach Sediment**

Scenario Timeframe: Current/Future
Medium: Sediment
Exposure Medium: Beach Sediment, Industrial Use

Exposure Point	CAS Number	Chemical <sup>a</sup>	Notes	Units	Minimum Detected Concentration	Maximum Detected Concentration	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits <sup>b</sup>	Concentration Used for Screening <sup>c</sup>	Screening Toxicity Value	COPC Flag (Y/N)	Rationale for Selection or Deletion
		Total DDD	k	ug/kg	1.1E+00	1.5E+00	LW2-B004	38%	4.5E-02 - 9.0E+00	7.2E+03	ca	N	Maximum detected value does not exceed screening value.
		Total DDT	l	ug/kg	3.3E-01	6.7E+00	LWG0106B029SDS015C00	50%	3.9E-01 - 1.2E+01	7.0E+03	ca	N	Maximum detected value does not exceed screening value.

**Notes:**

- a Chemicals listed include analytes detected in human health beach sediment samples from beaches designated as having potential for industrial use.
- b For chemical mixtures, the range of detection limits listed is the maximum and minimum detection limit for individual isomers or congeners within the mixture.
- c Screening concentrations and toxicity classifications are from EPA RSLs for industrial soil (Nov 2010) unless otherwise noted. RSLs for noncarcinogenic chemicals are divided by 10.
- d EPA RSL for trivalent chromium used for chromium screening concentration.
- e EPA RSL for lead not divided by 10 for screening.
- f EPA RSL for acenaphthene used as surrogate.
- g EPA RSL for pyrene used as surrogate.
- h EPA RSL for fluorene used as surrogate.
- i EPA RSL for PCBs as Aroclor 1254 used for screening concentration.
- j EPA RSL for 2,3,7,8-TCDD (Dioxin) used for screening concentration. Detection limits listed are for individual congeners/isomers before TEQ adjustment.
- k EPA RSL for DDD used for total DDD screening concentration.
- l EPA RSL for DDT used for total DDT screening concentration.

**Abbreviations:**

- ca = Carcinogen.
- CAS = Chemical Abstract Services number.
- COPC = Chemical of potential concern.
- EPA = U.S. Environmental Protection Agency.
- max = Ceiling limit recommended for screening value.
- mg/kg = Milligrams per kilogram.
- N = No.
- NA = Not applicable. Chemical detected at 100% frequency.
- nc = Noncarcinogen.
- RSL = Regional screening level.
- SVOC = Semivolatile organic compound.
- TEQ = Toxicity equivalent.
- Y = Yes.

		Total DDT	o ug/kg	9.2E-01	1.4E+02	LWG0107B024SDS015C00	30%	3.8E-01 - 2.6E+00	1.7E+03	ca	N	Maximum detected value does not exceed screening value.

**Notes:**

- a Chemicals listed include analytes detected in human health beach sediment samples from beaches designated as having potential for residential/recreational use.
- b For chemical mixtures, the range of detection limits listed is the maximum and minimum detection limit for individual isomers or congeners within the mixture.
- c Screening concentrations and toxicity classifications are from EPA RSLs for residential soil (Nov 2010) unless otherwise noted. RSLs for noncarcinogenic chemicals are divided by 10.
- d EPA RSL for trivalent chromium used for chromium screening concentration.
- e EPA RSL for lead not divided by 10 for screening.
- f EPA RSL for acenaphthene used as surrogate.
- g EPA RSL for pyrene used as surrogate.
- h EPA RSL for fluorene used as surrogate.
- i EPA RSL for PCBs as Aroclor 1254 used for screening value.
- j EPA RSL for 2,3,7,8-TCDD (Dioxin) used for screening value. Detection limits listed are for individual dioxin/furans before TEQ adjustment.
- k EPA RSL for endrin used as surrogate.
- l EPA RSL for chlordane used for total chlordane screening value.
- m EPA RSL for DDD used for total DDD screening value.
- n EPA RSL for DDE used for total DDE screening value.
- o EPA RSL for DDT used for total DDT screening value.

**Abbreviations:**

- ca = Carcinogen.
- CAS = Chemical Abstract Services number.
- COPC = Chemical of potential concern.
- EPA = U.S. Environmental Protection Agency.
- max = Ceiling limit recommended for screening value.
- mg/kg = Milligrams per kilogram.
- N = No.
- NA = Not applicable. Chemical detected at 100% frequency.
- nc = Noncarcinogen.
- RSL = Regional screening level.
- SVOC = Semivolatile organic compound.
- TEQ = Toxicity equivalent.
- Y = Yes.

	14797-73-0	Perchlorate		ug/kg	9.6E+04	2.7E+05	LWP1-CP07B	23%	2.2E+01 - 2.6E+01	7.2E+04	nc	Y	Maximum detected value exceeds screening value.

**Notes:**

- a Chemical list includes analytes detected in human health in-water sediment samples.
- b For chemical mixtures, the range of detection limits listed is the maximum and minimum detection limit for individual isomers or congeners within the mixture.
- c Screening concentrations and toxicity classifications are from EPA RSLs for industrial soil (Nov 2010) unless otherwise noted. RSLs for noncarcinogenic chemicals are divided by 10.
- d EPA RSL for chromium III used for chromium screening concentration.
- e EPA RSL for lead not divided by 10 for screening.
- f A screening value was not available and a surrogate chemical could not be identified. Analyte is discussed qualitatively in text.
- g EPA RSL for tributyltin oxide (TBTO) used as surrogate.
- h EPA RSL for naphthalene used as surrogate.
- i EPA RSL for pyrene used as surrogate.
- j EPA RSL for acenaphthene used as surrogate.
- k EPA RSL for fluorene used as surrogate.
- l EPA RSL for diethyl phthalate used as surrogate.
- m EPA RSL for 1,2-dichlorobenzene used as surrogate.
- n EPA RSL for 2-nitroaniline used as a surrogate.
- o EPA RSL for 2,3,4,6-tetrachlorophenol used as surrogate.
- p EPA RSL for PCBs as Aroclor 1254 used for screening concentration.
- q EPA RSL for 2,3,7,8-TCDD (Dioxin) used for screening concentration. Detection limits listed are for individual congeners/isomers before TEQ adjustment.
- r EPA RSL for endrin used as surrogate.
- s EPA RSL for technical chlordane used for total chlordane.
- t EPA RSL for DDD used for total DDD.
- u EPA RSL for p,p'-DDE used for total DDE.
- v EPA RSL for DDT used for total DDT.
- w EPA RSL for endosulfan used for total endosulfan.
- x EPA RSL for 2,4-D used as surrogate.
- y The trichloroethene screening level was calculated consistent with the 2008 EPA Region 10 recommendations (EPA 2008a).
- z DEQ risk-based concentration (RBC) for occupational surface soil exposure to generic diesel (DEQ 2003) used for screening concentration.
- aa DEQ risk-based concentration (RBC) for occupational surface soil exposure to generic gasoline (DEQ 2003) used for screening concentration.
- ab DEQ risk-based concentration (RBC) for occupational surface soil exposure to generic oil (DEQ 2003) used for screening concentration.

**Abbreviations:**

- |   |  |
|---|--|
| ca= Carcinogen.   | ne = Noncarcinogen.  |
| CAS = Chemical Abstract Services number.                  | RBC = Risk-based concentration.                                      |
| COPC = Chemical of potential concern.                     | sat = Soil saturation concentration recommended for screening value. |
| DEQ = Oregon Department of Environmental Quality.         | RSL = Regional Screening Level.                                      |
| EPA = U.S. Environmental Protection Agency.               | SVOC = Semivolatile organic compound.                                |
| max = Ceiling limit recommended for screening value.      | TEQ = Toxicity equivalent.   |
| mg/kg = Milligrams per kilogram.                          | Y = Yes.   |
| N = No.   |  |
| NA = Not applicable. Chemical detected at 100% frequency. |  |

**Table 2-13**  
**Occurrence, Distribution and Selection of Chemicals of Potential Concern - Surface Water, Direct Contact With Divers**

Scenario Timeframe: Current/Future
Medium: Water
Exposure Medium: Surface Water, Direct Contact With Divers

Exposure Point	Chemical <sup>a</sup>	Notes	Units	Minimum Detected Concentration	Maximum Detected Concentration	Location of Maximum Concentration	Date of Maximum Concentration	Detection Frequency	Range of Detection Limits <sup>b</sup>	Concentration Used for Screening <sup>c</sup>	Screening Toxicity Value	COPC Flag (Y/N)	Rationale for Selection or Deletion
	<b>Conventional</b> Perchlorate		ug/l	3.0E-01	1.6E+01	W016-2	11/30/2004	46%	- 2.0E-01 - 1.0E+00	2.6E+00	nc	Y	Maximum detected value exceeds screening value.

**Notes:** a Chemical list includes analytes detected in surface water samples determined to represent human health exposure to a diver from direct contact. Integrated samples have been averaged prior to screening. Benzo(j+k)fluoranthene is assumed to be entirely benzo(k)fluoranthene.

b For chemical mixtures, the range of detection limits listed is the maximum and minimum detection limit for individual isomers or congeners within the mixture.

c Screening concentrations and toxicity classifications are from EPA RSLs for tapwater (Nov 2010) unless otherwise noted. SLs for noncarcinogenic chemicals are divided by 10.

d EPA RSL for trivalent chromium used for chromium screening concentration.

e EPA action level for drinking water used for lead (May 2005). Screening level not divided by 10 for screening.

f EPA RSL was not available and a surrogate chemical could not be identified. Thallium MCL (May 2009) used as screening level.

g EPA RSL for tributyltin oxide (TBTO) used as surrogate.

h EPA RSL for acenaphthene used as surrogate.

i EPA RSL for pyrene used as surrogate.

j EPA Region 6 SL for tapwater (8 March 2008) used for Dimethyl phthalate.

k EPA RSL for diethyl phthalate used as surrogate.

l EPA RSL for PCBs as Aroclor 1254 used for screening concentration.

m EPA RSL for 2,3,7,8-TCDD (Dioxin) used for screening concentration.

n A screening value was not available and a surrogate chemical could not be identified. Analyte is discussed qualitatively in text.

o EPA RSL for endrin used as surrogate.

p EPA RSL for DDD used for total DDD.

q EPA RSL for p,p'-DDE used for total DDE.

r EPA RSL for DDT used for total DDT.

s EPA RSL for fluorene used as surrogate.

**Abbreviations:** ca = Carcinogen.

COPC = Chemical of potential concern.

EPA = U.S. Environmental Protection Agency.

MCL = Maximum Contaminant Level.

N = No.

NA = Not applicable. Chemical detected at 100% frequency, or screening value does not exist for given chemical.

nc = Noncarcinogen.

NL = Not listed.

pg/l = Picograms per liter.

RSL = Regional screening level.

SVOCs = Semivolatile organic compounds.

TEQ = Toxicity equivalent.

ug/l = Micrograms per liter.

Y = Yes.

	Benzoic acid		ug/l	1.2E+00	1.3E+00	W025	Jan-07	10%	1.8E+00 - 2.0E+00	1.5E+04	nc	N	Maximum detected value does not exceed screening value.
	Hexachlorobenzene		ug/l	1.6E-05	7.3E-05	W023	Mar-05	45%	4.8E-04 - 1.6E-02	4.2E-02	ca	N	Maximum detected value does not exceed screening value.
	Hexachlorobutadiene		ug/l	5.7E-07	4.1E-06	W025	Sep-06	29%	2.3E-07 - 2.2E-02	8.6E-01	ca	N	Maximum detected value does not exceed screening value.
	Isophorone		ug/l	7.1E-03	1.3E-02	W023M	Mar-07	6%	8.5E-03 - 9.5E-03	7.1E+01	ca	N	Maximum detected value does not exceed screening value.
	<b>Herbicides</b>												
	2,4-D		ug/l	5.2E-02	1.4E-01	W005	Nov-04	6%	3.4E-02 - 5.9E-02	3.7E+01	nc	N	Maximum detected value does not exceed screening value.
	2,4-DB		ug/l	1.4E-01	2.1E-01	W025	Sep-06	7%	4.1E-02 - 4.0E-01	2.9E+01	nc	N	Maximum detected value does not exceed screening value.
	MCPP		ug/l	8.0E+00	9.1E+00	W005	Sep-06	7%	6.0E+00 - 1.1E+02	3.7E+00	nc	Y	Maximum detected value exceeds screening value.

- Notes:** a Chemical list includes analytes detected in surface water samples determined to represent human health exposure from direct contact. Integrated samples have been averaged prior to screening. Benzo(j+k)fluoranthene is assumed to be entirely benzo(k)fluoranthene.  
b For chemical mixtures, the range of detection limits listed is the maximum and minimum detection limit for individual isomers or congeners within the mixture.  
c Screening concentrations and toxicity classifications are from EPA RSLs for tapwater (Nov 2010) unless otherwise noted. SLs for noncarcinogenic chemicals are divided by 10.  
d EPA RSL for trivalent chromium used for chromium screening concentration.  
e EPA MCL for tapwater used for lead. Screening level not divided by 10 for screening.  
f Regional screening value was not available and a surrogate chemical could not be identified. Thallium MCL used as screening level.  
g EPA RSL for tributyltin oxide (TBTO) used as surrogate.  
h EPA RSL for acenaphthene used as surrogate.  
i EPA RSL for pyrene used as surrogate.  
j EPA RSL for diethyl phthalate used as surrogate.  
k EPA RSL for PCBs as Aroclor 1254 used for screening concentration.  
l EPA RSL for 2,3,7,8-TCDD (Dioxin) used for screening concentration.  
m A screening value was not available and a surrogate chemical could not be identified. Analyte is discussed qualitatively in text.  
n EPA RSL for endrin used as surrogate.  
o EPA RSL for DDD used for total DDD.  
p EPA RSL for p,p'-DDE used for total DDE.  
q EPA RSL for DDT used for total DDT.

- Abbreviations:** ca = Carcinogen.  
CAS = Chemical Abstract Services.  
COPC = Chemical of potential concern.  
EPA = U.S. Environmental Protection Agency.  
MCL = Maximum Contaminant Level. National Primary Drinking Water Regulations. EPA 2010.  
N = No.  
NA = Not applicable. Chemical detected at 100% frequency, or screening value does not exist for given chemical.  
nc = Noncarcinogen.  
NL = Not listed.  
pg/l = Picograms per liter.  
RSL = Regional screening level.  
SVOC = Semivolatile organic compound.  
TEQ = Toxicity equivalent.  
ug/l = Micrograms per liter.  
Y = Yes.

**Notes:**

- a Groundwater seep data represent groundwater that has seeped into holes of the outfall pipe at the given location.
- b Chemical list includes analytes detected in Outfall 22B samples in the site characterization and risk assessment (SCRA) dataset from the past 10 years that were not from stormwater sampling events.
- c Screening concentrations and toxicity classifications are from EPA RSLs for tap water (Nov 2010). SLs for noncarcinogenic chemicals are divided by 10.
- d EPA RSL for chromium III used as a surrogate for chromium.
- e EPA Region 6 SL for tap water used for lead. SL not divided by 10 for screening.
- f EPA RSL for pyrene used as surrogate.
- g EPA RSL for nitrobenzene used as surrogate.
- h EPA RSL for 2,3,7,8-TCDD (dioxin) used for screening concentration. Range of detection limits listed is for individual dioxin/furan isomers before TEQ adjustment.
- i EPA RSL for DDE used for total DDE. Range of detection limits listed is for individual DDE isomers.
- j The trichloroethene screening level was calculated consistent with the 2008 EPA Region 10 recommendations (EPA 2008a).

**Abbreviations:**

- ca = Carcinogen.
- CAS = Chemical Abstract Services.
- COPC = Chemical of potential concern.
- DEQ = Oregon Department of Environmental Quality.
- EPA = U.S. Environmental Protection Agency.
- N = No.
- NA = Not applicable. Chemical detected at 100% frequency.
- nc = Noncarcinogen.
- RBC = Risk-based concentration.
- RSL = Regional screening level.
- SVOC = Semivolatile organic compound.
- TEQ = Toxicity equivalent.
- ug/l = Micrograms per liter.
- VOC = Volatile organic compound.
- Y = Yes.

	Total DDE	p	ug/l	1.7E-05	4.8E-04	W037	Jan-07	7.0E-01	2.6E-04 - 7.8E-04	2.0E-01	NA	ca	N	Maximum detected values does not exceed screening value.
	Total DDT	q	ug/l	3.8E-06	2.8E-03	W030	Nov-06	7.5E-01	4.1E-04 - 1.1E-03	2.0E-01	NA	ca	N	Maximum detected values does not exceed screening value.
	Total Endosulfan		ug/l	6.1E-05	7.2E-04	W026	Nov-06	7.0E-01	3.1E-04 - 5.1E-04	2.2E+01	NA	nc	N	Maximum detected values does not exceed screening value.
	<b>SVOCs</b>													
	4-Chloroaniline		ug/l	1.3E-02	1.3E-02	W023	Jan-07	1.6E-02	1.8E-02 - 2.0E-02	3.4E-01	NA	ca	N	Maximum detected values does not exceed screening value.
	Aniline		ug/l	1.2E+00	1.2E+00	W035	Jan-07	1.6E-02	2.5E-01 - 1.2E+00	1.2E+01	NA	ca	N	Maximum detected values does not exceed screening value.
	Benzoic acid		ug/l	1.2E+00	2.1E+00	W026	Nov-06	9.4E-02	1.8E+00 - 2.0E+00	1.5E+04	NA	nc	N	Maximum detected values does not exceed screening value.
	Carbazole	r	ug/l	8.3E-02	8.3E-02	W031	Jan-07	1.6E-02	1.3E-02 - 1.5E-02	1.5E+02	NA	nc	N	Maximum detected values does not exceed screening value.
	Dibenzofuran		ug/l	2.5E-02	2.5E-02	W031	Jan-07	1.6E-02	5.7E-03 - 2.9E-02	3.7E+00	NA	nc	N	Maximum detected values does not exceed screening value.
	Hexachlorobenzene		ug/l	1.3E-05	4.1E-03	W036	Jan-07	4.3E-01	3.1E-04 - 1.6E-02	4.2E-02	1	ca	N	Maximum detected values does not exceed screening value.
	Hexachlorobutadiene		ug/l	5.7E-07	3.6E-05	W034	Nov-06	1.8E-01	2.3E-07 - 2.2E-02	8.6E-01	NA	ca	N	Maximum detected values does not exceed screening value.
	Isophorone		ug/l	7.1E-03	1.3E-02	W023M	Mar-07	6.3E-02	8.5E-03 - 9.5E-03	7.1E+01	NA	ca	N	Maximum detected values does not exceed screening value.
	<b>Herbicides</b>													
	2,4-D		ug/l	4.7E-02	1.6E-01	W035	Jan-07	7.8E-02	3.4E-02 - 1.7E-01	3.7E+01	70	nc	N	Maximum detected values does not exceed screening value.
	2,4-DB		ug/l	1.4E-01	2.1E-01	W025	Sep-06	3.3E-02	4.0E-02 - 4.1E-01	2.9E+01	NA	nc	N	Maximum detected values does not exceed screening value.
	Dalapon		ug/l	2.6E-01	2.6E-01	W036	Jan-07	1.6E-02	1.8E-01 - 6.7E-01	1.1E+02	200	nc	N	Maximum detected values does not exceed screening value.
	MCPP		ug/l	5.2E+00	1.9E+01	W035	Jan-07	9.8E-02	6.0E+00 - 1.1E+02	3.7E+00	NA	nc	Y	Maximum detected value exceeds screening value.
	<b>Conventionals</b>													
	Perchlorate		ug/l	3.0E-01	3.0E-01	W033	Nov-06	1.4E-01	2.0E-01 - 7.0E-01	2.6E+00	NA	nc	N	Maximum detected values does not exceed screening value.

- Notes:** a Chemical list includes analytes detected in surface water samples determined to represent potential future human health exposure from surface water as a drinking water source. Data set includes all vertically integrated and combined transect samples within the study area. Integrated samples have been averaged prior to screening. Benzo(j+k)fluoranthene is assumed to be entirely benzo(k)fluoranthene.  
b For chemical mixtures, the range of detection limits listed is the maximum and minimum detection limit for individual isomers or congeners within the mixture.  
c Screening concentrations and toxicity classifications are from EPA RSLs for tap water (Nov2010) unless otherwise noted. RSLs for noncarcinogenic chemicals are divided by 10.  
d Maximum Contaminant Levels used as screening concentrations are from EPA 816-F-09-004, May 2009. Retrieved online 15 October 2010.  
e EPA RSL listed is for trivalent chromium; MCL listed is for total chromium.  
f EPA RSL for tributyltin oxide (TBTO) used as surrogate.  
g EPA RSL for acenaphthene used as surrogate.  
h Benzo(a)pyrene MCL used for screening of all carcinogenic PAHs  
i EPA RSL for pyrene used as surrogate.  
j EPA RSL for diethyl phthalate used as surrogate.  
k EPA RSL for PCBs as Aroclor 1254 used for screening concentration.  
l EPA RSL for 2,3,7,8-TCDD (dioxin) used for screening concentration.  
m A screening value was not available and a surrogate chemical could not be identified. Analyte is discussed qualitatively in text.  
n EPA RSL for endrin used as surrogate.  
o EPA RSL for DDD used for total DDD.  
p EPA RSL for p,p'-DDE used for total DDE.  
q EPA RSL for DDT used for total DDT.  
r EPA RSL for fluorene used as surrogate.

**Abbreviations:** ca = Carcinogen.  
CAS = Chemical Abstract Services.  
COPC = Chemical of potential concern.  
EPA = U.S. Environmental Protection Agency.  
MCL = Maximum Contaminant Level.  
N = No.  
NA = Not applicable. Chemical detected at 100% frequency, or screening value does not exist for given chemical.  
nc = Noncarcinogen.

NL = Not listed.  
pg/l = Picograms per liter.  
RSL = Regional screening level.  
SVOC = Semivolatile organic compound.  
TEQ = Toxicity equivalent.  
ug/l = Micrograms per liter.  
Y = Yes.  
PAH = Polynuclear aromatic hydrocarbons

**TABLE 3-2**  
**Exposure Point Concentration Summary - Beach Sediment, Industrial-Land Use**

Scenario Timeframe: Current/Future
Medium: Sediment
Exposure Medium: Beach Sediment, Industrial Use

Exposure Point	Chemical of Potential Concern	Units	Non-Detects	Total Samples <sup>a</sup>	Arithmetic Mean	Maximum Detected Concentration	95% UCL			Exposure Point Concentration <sup>b</sup>	
							Distribution	95% UCL Method	Value	Mean	95% UCL/Max
	<b>Polychlorinated Biphenyls</b>										
	Total Aroclors	ug/kg	0	1	1.7E+01	1.7E+01				1.7E+01	1.7E+01
	<b>Dioxin/Furans</b>										
	Total PCB TEQ	pg/g	NA	NA	NA	NA				NA	NA

**Notes:**

- a Total number of samples includes number of samples in dataset, regardless of detection status. No non-detects exceeded the maximum detected concentration.
- b Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- c 95% UCL not calculated for analytes with fewer than five detects.

**Abbreviations:**

- 95% UCL = 95% Upper confidence limit.
- mg/kg = Milligrams per kilogram.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected.
- PCB = Polychlorinated biphenyls.
- pg/g = Picograms per gram.
- TEQ = Toxic equivalence quotient.
- ug/kg = Micrograms per kilogram.

**TABLE 3-3.**  
**Exposure Point Concentration Summary - Beach Sediment, Transients, Recreational Users, and Bank Fishers**

Scenario Timeframe: Current/Future
Medium: Sediment
Exposure Medium: Beach Sediment, Use by Transients, Recreational Users, and Bank Fishers

Exposure Point	Chemical of Potential Concern	Units	Non-Detects	Total Samples <sup>a</sup>	Arithmetic Mean	Maximum Detected Concentration	95% UCL			Exposure Point Concentration <sup>b</sup>	
							Distribution	95% UCL Method	Value	Mean	95% UCL/Max
	Dibenzo(a,h)anthracene	ug/kg	0	1	1.5E+01	1.5E+01				1.5E+01	1.5E+01
	Indeno(1,2,3-cd)pyrene	ug/kg	0	1	1.3E+02	1.3E+02				1.3E+02	1.3E+02

**Notes:**

- a Total number of samples includes number of samples in dataset, regardless of detection status. No non-detects exceeded the maximum detected concentration.
- b Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- c 95% UCL not calculated for analytes with fewer than five detects.

**Abbreviations:**

- 95% UCL = 95% Upper confidence limit.
- mg/kg = Milligrams per kilogram.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected.
- ug/kg = Micrograms per kilogram.

**TABLE 3-4.**  
**Exposure Point Concentration Summary - In-water Sediment**

Scenario Timeframe: Current/Future
Medium: Sediment
Exposure Medium: In-Water Sediment

Exposure Point <sup>a</sup>	Chemical of Potential Concern	Units	Total Samples	Total Non-Detects <sup>b</sup>	Non-Detects greater than Maximum Detected Concentration <sup>c</sup>	Arithmetic Mean <sup>d</sup>	Maximum Detected Concentration	95% UCL			Exposure Point Concentration <sup>e</sup>	
								Distribution	95% UCL Method	Value	Mean	95% UCL/Max
	<b>Conventional</b> Perchlorate	ug/kg	13	10	0	4.9E+04	2.7E+05	--	Fewer than 5 detects	--	4.9E+04	2.7E+05

**Notes:**

- a Exposure points for in-water sediment are per half river mile, per side of river. No samples within the human health data set were taken at exposure area of RM 11.5 East, and therefore it is not listed in the table. In-water sediment data set for human health includes in-water sediment samples taken from less than 30.5 centimeters in depth and outside of the navigation channel.
- b Total number of non-detects in the dataset.
- c Number of non-detects with detection limit exceeding the maximum detected concentration for the given exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- d Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- e Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- f 95% UCL not calculated for analytes with fewer than five detects.
- g "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations.
- h Study Area-wide data set includes samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

- = Not Applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit on the mean.
- DDT = Dichlorodiphenyltrichloroethane.
- MC = Multnomah Channel.
- mg/kg = Milligrams per kilogram.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected. Chemical not detected in given exposure area.
- PCB = Polychlorinated Biphenyls.
- pg/g = Picograms per gram.
- RM = River mile.
- SIL = Swan Island Lagoon.
- TEQ = Toxic equivalents.
- ug/kg = Micrograms per kilogram.

**Notes:**

- a The surface water exposure dataset for direct contact to divers includes samples from all transects and all single point stations within the study area. In addition, EPCs were calculated for Multnomah Channel.
- b The surface water exposure dataset for direct contact to transients includes year-round samples from transects and single point stations within the study area where transients exposure may occur. In addition, EPCs were calculated for Multnomah Channel.
- c The surface water exposure dataset for direct contact to recreational beach users includes samples from summer sampling events at single point stations within the study area where recreational beach exposure may occur. In addition, study area wide EPCs were calculated using summer samples from all transect stations within the study area.
- d The surface water exposure dataset for the scenario describing the potential future domestic use of untreated surface water includes all vertically integrated and combined transect samples within the study area.
- e "Int" indicates sample results with this sample ID were combined to represent an integrated concentration before EPC calculations. Either results from a near-bottom and near-surface sample pair were combined, or results from vertically integrated samples collected from the east, west, and middle sections of the river were combined, according to the rules discussed in Section 2 of the BHHRA.
- f "Comb" or "Combo" is included in sample IDs for samples collected with an XAD-2 Infiltrax™ 300 system, indicating both column and filter results were combined before EPC calculations, according to the rules discussed in Section 2 of the BHHRA.

**Abbreviations:**

- = Not applicable. Sample was not used for EPC calculations for the given exposure scenario.
- BHHRA = Baseline human health risk assessment.
- Comb or Combo = Combined column and filter results (for XAD samples only). See footnote f.
- E = East.
- EPC = Exposure point concentration.
- Int = Integrated sample results (calculated). See footnote e.
- MC = Multnomah Channel.
- SIL = Swan Island Lagoon.
- W = West.
- Y = sample was used for EPC calculations for the given receptor.

Notes:

- a Total number of non-detects in the dataset.
- b Number of non-detects with detection limit exceeding the maximum detected concentration for a given exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- c Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- d Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- e 95% UCL not calculated for analytes with fewer than five detects.
- f Study Area-wide data set for transient exposure includes year-round transect samples from the following stations: W005, W011, W023, and W025.

Abbreviations:

- = Not applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit.
- MC = Multnomah Channel.
- MCP = 2-(2-Methyl-4-chlorophenoxy)propionic acid.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected. Chemical not detected in given exposure area.
- ug/l = Micrograms per liter.

**Notes:**

- a Exposure areas for divers are ½ - mile reaches per side of river throughout the study area, where single point samples from RM 2.0 - 2.4 are in exposure area 2.0, samples from RM 2.5 - 2.9 are in exposure area 2.5, etc. Each transect sample represents its own exposure area, and is listed individually. River mile segments not listed indicate there are no human health surface water samples from that river reach. Swan Island Lagoon and Multnomah Channel are their own exposure areas.
- b Total number of non-detects in the dataset.
- c Number of non-detects with detection limit exceeding the maximum detected concentration for a given exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- d Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- e Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- f 95% UCL not calculated for analytes with fewer than five detects.

**Abbreviations:**

- = Not applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit on the mean.
- MCPP = 2-(2-Methyl-4-chlorophenoxy)propionic acid.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected. Chemical not detected in given exposure area.
- RM = River mile.
- SIL = Swan Island Lagoon.
- ug/l = Micrograms per liter.
- MC = Multnomah Channel.

**TABLE 3-9.**  
**Exposure Point Concentration Summary - Surface Water, Residential Use as a Domestic Water Source**

Scenario Timeframe: Potential Future
Medium: Water
Exposure Medium: Surface Water, Domestic Water Source

Exposure Point	Chemical of Potential Concern	Units	Total Samples	Total Non-Detects <sup>a</sup>	Non-Detects greater than Maximum Detected Concentration <sup>b</sup>	Arithmetic Mean <sup>c</sup>	Maximum Detected Concentration	95% UCL			Exposure Point Concentration <sup>d</sup>	
								Distribution	95% UCL Method	Value	Mean	95% UCL/Max
	<b>Herbicides</b> MCP	ug/l ug/l	61	55	6	7.7E+00	1.9E+01	normal	95% KM (t) UCL	6.4E+00	7.7E+00	6.4E+00

**Notes:**

- a Total number of non-detects in the dataset.
- b Number of non-detects with detection limit exceeding the maximum detected concentration for the given exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- c Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- d Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- e 95% UCL not calculated for analytes with fewer than five detects.
- f Study Area-wide data set includes samples from all individual exposure points within the Study Area.

**Abbreviations:**

- = Not Applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit on the mean.
- MCP = 2-(2-Methyl-4-chlorophenoxy)propionic acid.
- ND = Not detected. Chemical not detected in given exposure area.
- ug/l = Micrograms per liter.

Notes:

- a Exposure areas for smallmouth bass tissue are on a RM basis, such that samples collected from RM 1 5 - 2 5 are included in exposure area RM 2, samples collected from RM 2 5-3 5 are included in exposure area RM 3, etc Swan Island Lagoon is its own exposure area
- b Chemicals listed are analytes detected in each tissue type at least once within the Study Area
- c Total number of non-detects in the dataset
- d Number of non-detects with detection limit exceeding the maximum detected concentration for the exposure area These non-detects were removed from the dataset prior to calculation of EPCs
- e Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit
- f Exposure point concentration is the lesser value of maximum or 95%UCL
- g 95% UCL not calculated for analytes with fewer than five detects
- h "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations
- i Swan Island Lagoon EPCs for fillet tissue calculated by applying ratio of Study-area Wide Fillet mean concentration/Study-area Wide Whole Body mean concentration to the Swan Island Lagoon Whole Body EPC

Abbreviations:

-- = Not applicable A 95% UCL could not be computed for the given data set  
 95% UCL = 95% Upper confidence limit on the mean  
 DDD = Dichlorodiphenyldichloroethane  
 DDE = Dichlorodiphenyldichloroethylene  
 DDT = Dichlorodiphenyltrichloroethane  
 F = Fillet tissue All smallmouth bass fillet tissue was analyzed as fillet with skin, except mercury, which was analyzed as fillet without skin  
 mg/kg = Milligrams per kilogram  
 NA = Not available Chemical not analyzed or had rejected result for given exposure area

ND = Not detected in the given exposure area  
 PCB = Polychlorinated biphenyls  
 pg/g = Picograms per gram  
 RM = River mile  
 TEQ = Toxic equivalents  
 ug/kg = Micrograms per kilogram  
 WB= Whole body

			Total Endosulfan	ug/kg	4	3	1	7.0E-01	1.1E+00				1.1E+00

**Notes:**

- a Chemicals listed are analytes detected in each tissue type at least once within the Study Area.
- b Total number of non-detects in the dataset.
- c Number of non-detects with detection limit exceeding the maximum detected concentration for the exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- d Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- e Exposure point concentration is the lesser value of maximum or 95%UCL.
- f 95% UCL not calculated for analytes with fewer than five detects.
- g "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations.

**Abbreviations:**

- = Not applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit on the mean.
- DDD = Dichlorodiphenyldichloroethane.
- DDE = Dichlorodiphenyldichloroethylene.
- DDT = Dichlorodiphenyltrichloroethane.
- F = Fillet tissue. All smallmouth bass, carp, and crappie fillet tissue was analyzed as fillet with skin, except mercury, which was analyzed as fillet without skin. All brown bullhead fillet tissue was analyzed as fillet without skin.
- mg/kg = Milligrams per kilogram.
- PCB = Polychlorinated biphenyls.
- pg/g = Picograms per gram.
- TEQ = Toxic equivalents.
- ug/kg = Micrograms per kilogram.
- WB= Whole body.

- b Chemicals listed are analytes detected at least once within the BHHRA data set for this species.
- c Total number of non-detects in the dataset.
- d Number of non-detects with detection limit exceeding the maximum detected concentration for the exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- e Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- f Exposure point concentration is lesser value of the 95% UCL or maximum.
- g 95% UCL not calculated for analytes with fewer than five detects.
- h "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations.

**Abbreviations:**

- 95% UCL = 95% Upper confidence limit on the mean.
- BHHRA = Baseline human health risk assessment.
- mg/kg = Milligrams per kilogram.
- PCB = Polychlorinated biphenyl.
- pg/g = Picograms per gram.
- TEQ = Toxic equivalents.
- ug/kg = Micrograms per kilogram.
- WB = Whole body tissue.

TABLE 3-16  
Exposure Point Concentration Summary - Multi-Species Diet, Study Area-Wide

Scenario Timeframe: Current/Future
Medium: Fish Tissue
Exposure Medium: Multi-species

Exposure Point	Tissue Type	Chemical of Potential Concern <sup>a</sup>	Units	Recreational and Subsistence Fishers <sup>b</sup>					Tribal Fishers <sup>b</sup>							
				Smallmouth Bass	Common Carp	Brown Bullhead	Black Crappie	Multi-Species EPC <sup>c,d</sup>	Smallmouth Bass	Common Carp	Brown Bullhead	Black Crappie	Salmon <sup>e</sup>	Lamprey <sup>f</sup>	Sturgeon <sup>g</sup>	Multi-Species EPC <sup>h,i,j</sup>
		Total DDT	ug/kg	NC	NC	NC	NC	NC	1.6E+01	4.6E+00	5.5E+00	2.7E+00	5.2E-01	ND	3.6E+00	3.3E+01
		Total Endosulfan	ug/kg	NC	NC	NC	NC	NC	3.6E-01	4.6E-01	1.1E+00	1.4E-01	3.8E-01	ND	5.4E-02	2.5E+00

Notes:

a Chemicals listed for fillet exposure are analytes detected in Study Area-wide fillet tissue samples of resident species. Chemicals listed for whole body exposure are analytes detected in whole body tissue samples of resident species (smallmouth bass, black crappie, common carp, brown bullhead).

b EPC values represent the lower value of the calculated maximum or 95% Upper confidence limit on the mean.

c For recreational and subsistence non-tribal fishers, EPCs for the multi-species diet were calculated assuming each of the four target fish species (smallmouth bass, black crappie, common carp, and brown bullhead) represent 1/4 of a person's diet, according to the Portland Harbor RI/FS Programmatic Work Plan.

d Numbers presented are rounded values. Sums calculated before rounding.

e Chinook salmon samples were taken at Clackamas fish hatchery, outside of initial study area; samples represent EPCs for Study Area locations.

f Lamprey samples were taken at Willamette Falls, outside of initial study area; samples represent EPCs for Study Area locations.

g Sturgeon samples were taken between Willamette River miles 3.5 and 9.2.

h The Tribal multi-species fish diet EPCs were calculated assuming different ingestion rates for each of seven fish species, which can also be represented by that species' percent of total fish diet. The EPCs shown in the table are the weighted sums of the EPCs for the individual species based on the following percentages:

- (38.4% x Salmon EPC)
- + (7.0% x Lamprey EPC)
- + (4.9% x Sturgeon EPC)
- + (12.4% x Smallmouth Bass EPC)
- + (12.4% x Black Crappie EPC)
- + (12.4% x Common Carp EPC)
- + (12.4% x Brown Bullhead EPC)
- 100% Tribal fish tissue diet EPC

i Fillet Tissue EPCs are based on Study Area-wide fillet tissue EPCs for each of the target resident species (smallmouth bass, black crappie, common carp, brown bullhead), and the available tissue data from the ODHS sampling effort, which are: fillet (with skin) Chinook salmon, whole body lamprey, and fillet (no skin) sturgeon.

j Whole Body Tissue EPCs are based on Study Area-wide whole body EPCs for each of the target resident species (smallmouth bass, black crappie, common carp, brown bullhead), and the available tissue data from the ODHS sampling effort, which are: whole body Chinook salmon, whole body lamprey, and fillet tissue (no skin) sturgeon.

k "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCB concentrations.

Abbreviations:

- DDD = Dichlorodiphenyldichloroethane
- DDE = Dichlorodiphenyldichloroethylene
- DDT = Dichlorodiphenyltrichloroethane
- F = Fillet tissue. All resident fish fillet tissue was analyzed as fillet with skin, except mercury, which was analyzed as fillet without skin.
- mg/kg = Milligrams per kilogram
- NA = Not analyzed
- NC = Not calculated. Multi-species EPCs based on resident fish WB EPCs calculated for tribal fisher scenarios only.

- ND = Not detected in the given species and tissue type
- PCB = Polychlorinated biphenyls
- pg/g = Picograms per gram
- TEQ = Toxic equivalents
- ug/kg = Micrograms per kilogram
- WB = Whole body

		Total Endosulfan	ug/kg	1	1	0	ND	ND				ND

**Notes:**

- a Each crayfish sampling location is its own exposure area.
- b Chemicals listed are analytes detected at least once within the Study Area.
- c Total number of non-detects in the dataset.
- d Number of non-detects with detection limit exceeding the maximum detected concentration for the exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- e Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- f 95% UCL not calculated for analytes with fewer than five detects.
- g "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations.

**Abbreviations:**

- 95% UCL = 95% Upper confidence limit on the mean.
- DDD = Dichlorodiphenyldichloroethane.
- DDE = Dichlorodiphenyldichloroethylene.
- DDT = Dichlorodiphenyltrichloroethane.
- mg/kg = Milligrams per kilogram.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected in the given exposure area.
- PCB = Polychlorinated biphenyls.
- pg/g = Picograms per gram.
- RM = River mile.
- SIL = Swan Island Lagoon.
- TEQ = Toxic equivalents.
- ug/kg = Micrograms per kilogram.
- WB= Whole body.

Notes:

- a Exposure areas for clam tissue are on a RM basis per side of river, such that samples collected from RM 3.0 - 3.9 west of the navigation channel are included in exposure area RM 3 West, etc. Swan Island Lagoon is its own exposure area.
- b Chemicals listed are analytes detected in each tissue type at least once within the Study Area.
- c Total number of non-detects in the dataset.
- d Number of non-detects with detection limit exceeding the maximum detected concentration for the exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- e Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- f 95% UCL not calculated for analytes with fewer than five detects.
- g "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations.

Abbreviations:

- = Not applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit on the mean.
- D = Depurated tissue.
- DDD = Dichlorodiphenyldichloroethane.
- DDE = Dichlorodiphenyldichloroethylene.
- DDT = Dichlorodiphenyltrichloroethane.
- mg/kg = Milligrams per kilogram.
- NA = Not available. Chemical not analyzed or had rejected result for given exposure area.
- ND = Not detected in the given exposure area.

- PCB = Polychlorinated biphenyls.
- pg/g = Picograms per gram.
- RM = River mile.
- TEQ = Toxic equivalents.
- UD = Undepurated tissue.
- ug/kg = Micrograms per kilogram.

Notes:

- a Chemicals listed are analytes detected in each tissue type at least once within the Study Area.
- b Total number of non-detects in the dataset.
- c Number of non-detects with detection limit exceeding the maximum detected concentration for the exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- d Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- e 95% UCL not calculated for analytes with fewer than five detects.
- f "Total PCBs, Adjusted" equals "Total PCB Congeners" minus the sum of total dioxin-like PCBs concentrations.

Abbreviations:

- = Not applicable. A 95% UCL could not be computed for the given data set.
- 95% UCL = 95% Upper confidence limit on the mean.
- D = Depurated tissue.
- DDD = Dichlorodiphenyldichloroethane.
- DDE = Dichlorodiphenyldichloroethylene.
- DDT = Dichlorodiphenyltrichloroethane.
- mg/kg = Milligrams per kilogram.
- PCB = Polychlorinated biphenyls.
- pg/g = Picograms per gram.
- RM = River mile.
- TEQ = Toxic equivalents.
- UD = Undepurated tissue.
- ug/kg = Micrograms per kilogram.

**Notes:**

- a Exposure points for in-water sediment are per half river mile, per side of river. No samples within the human health data set were taken at exposure area of RM 11.5 East, and therefore it is not listed in the table. In-water sediment data set for human health includes in-water sediment samples taken from less than 30.5 centimeters in depth and outside of the navigation channel.
- b Chemicals of potential concern include all PBDE congeners detected in the BHHRA in-water sediment dataset, which is described in Section 2.
- c Total number of non-detects in the dataset.
- d Number of non-detects with detection limit exceeding the maximum detected concentration for the given exposure area. These non-detects were removed from the dataset prior to calculation of EPCs.
- e Non-detects less than the maximum detected concentration for a given exposure area are included in the arithmetic mean at half the detection limit.
- f Mean exposure point concentrations were used for Central Tendency (CT) exposure and 95% UCL/Max exposure point concentrations were used for Reasonable Maximum Exposure (RME) in the BHHRA.
- g 95% UCL not calculated for analytes with fewer than five detects.
- h Study Area-wide data set includes samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable. A 95% UCL could not be computed for the given data set.  
95% UCL = 95% Upper confidence limit on the mean.

RM = River mile.  
ug/kg = micrograms per kilogram.

ND = Not detected. Chemical not detected in given exposure area.

Table 4-1  
Cancer Toxicity Data - Oral/Dermal

CAS Number	Chemical of Potential Concern	Notes	Oral Cancer Slope Factor (mg/kg-day) <sup>-1</sup>	Oral Absorption Efficiency for	Absorbed Cancer Slope Factor for Dermal (mg/kg-day) <sup>-1</sup>	Oral CSF Source(s), Date <sup>2</sup>	Weight of Evidence for Carcinogenicity, listed under IRIS
79-01-6	Trichloroethene <b>Conventional</b>	q	8.9E-02	1	8.9E-02	C, Nov 2010	Information reviewed but value not estimated.
14797-73-0	Perchlorate		--	1	--	--	Not assessed under IRIS program.

**Footnotes:**

- 1 Exhibit 4-1. Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
- 2 Oral cancer slope factors were retrieved from the EPA Regional Screening Levels (RSL) Tables (November 2010), which uses the EPA recommended hierarchy for toxicity value sources. Sources listed above are those listed in the RSL table.

**Acronyms:**

- Not evaluated as a carcinogen
- A Agency for Toxic Substances and Disease Registry Minimum Risk Level
- C California EPA Office of Environmental Health Hazard Assessment, as referenced in RSL table
- CAS Chemical Abstracts Service
- CSF cancer slope factor
- E Environmental Criteria and Assessment Office, as referenced in RSL table
- EPA United States Environmental Protection Agency
- IRIS Integrated Risk Information System, Accessed online November 2010.
- J New Jersey Department of Environmental Protection, as referenced in RSL table
- mg/kg-day milligram per kilogram per day
- NA Not applicable. Chemical is not assessed individually for cancer risk.
- NL Not Listed
- P Provisional Peer Reviewed Toxicity Value
- TEQ Toxic equivalency quotient

**Notes:**

- a EPA lists an oral absorption efficiency of 2.5% and 5% for water and diet dosing regimens, respectively. The higher value of 5% is listed.
- b Lead not evaluated using cancer slope factor.
- c Methylmercury toxicity value used for tissue evaluation.
- d Toxicity value for mercuric chloride (and other Mercury salts) used for evaluation of mercury in sediment.
- e A toxicity value was not available from the recommended hierarchy and a surrogate chemical could not be identified. Analyte is discussed qualitatively in text.
- f Surrogate: Tributyltin oxide
- g Surrogate: Acenaphthene
- h Surrogate: Pyrene
- i Surrogate: Fluorene
- j Surrogate: Dibutyl phthalate
- k Surrogate: 4-Methylphenol
- l Not applicable. PCB Congeners are not assessed as a total sum for cancer risk. Adjusted PCBs and PCB TEQ assessed for cancer risk.
- m Toxicity value used for PCB congeners is the upper bound slope factor, based on high risk and persistence.
- n TEQ approach based on 2,3,7,8-TCDD toxicity
- o Surrogate: Endrin
- p Cancer slope factor is for the 4,4' isomer
- q Per an agreement with EPA, toxicity value for trichloroethene is based on EPA. 2001b. Trichloroethylene Health Risk Assessment: Synthesis and Characterization, August 2001, EPA/600/P-01/0002A – External Review Draft. The toxicity value for trichloroethene represents an older value that is superseded by more recent guidance. The use of the older toxicity value does not impact the conclusions of the risk assessment.

**Footnotes:**

- Source: Exhibit 4-1 Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004 EPA/540/R/99/005
- Oral RfD toxicity values were retrieved from the EPA Regional Screening Levels (RSLs) Table (November 2010), which uses the EPA recommended hierarchy for toxicity value sources. Sources listed above are those listed in the RSL table.

**Acronyms:**

- Not available
- A Agency for Toxic Substances and Disease Registry, as referenced in RSL table
- ATSDR MRL Agency for Toxic Substances and Disease Registry Minimum Risk Level
- CAS Chemical Abstracts Service
- CNS Central Nervous System
- EPA United States Environmental Protection Agency
- H Health Effects Assessment Summary Table, July 1997
- IRIS Integrated Risk Information System, Accessed online November 2010
- mg/kg-day milligram per kilogram per day
- NA Not applicable. Chemical will not be assessed individually for noncancer risk
- NL Not Listed
- P Provisional Peer Reviewed Toxicity Value
- RfD Reference Dose
- TEQ Toxic equivalency quotient
- X Provisional Peer Reviewed Toxicity Value Appendix, as referenced in RSL table

**Notes:**

- a EPA lists an oral absorption efficiency of 2.5% and 5% for water and diet dosing regimens, respectively. The higher value of 5% is listed.
- b Lead not evaluated using reference dose
- c Methylmercury toxicity value used for tissue evaluation
- d Toxicity value for mercuric chloride (and other mercury salts) used for mercury in sediment evaluation
- e A toxicity value was not available from the recommended hierarchy and a surrogate chemical could not be identified. Analyte is discussed qualitatively in text.
- f Toxicity value calculated from vanadium pentoxide. Critical effect listed is for vanadium pentoxide.
- g Surrogate: Tributyltin Oxide
- h Surrogate: Acenaphthene
- i Surrogate: Pyrene
- j Surrogate: Fluorene
- k Surrogate: Dibutyl phthalate
- l Surrogate: 4-Methylphenol
- m RfDo for Aroclor 1254
- n Not applicable. Chemical will not be assessed individually for noncancer risk
- o TEQ approach based on 2,3,7,8-TCDD toxicity
- p Surrogate: Endrin
- q RfDo for DDT
- r Per an agreement with EPA, toxicity value for trichloroethene is based on EPA 2001b Trichloroethylene Health Risk Assessment: Synthesis and Characterization, August 2001, EPA/600/P-01/0002A – External Review Draft. The toxicity value for trichloroethene represents an older value that is superseded by more recent guidance. The use of the older toxicity value does not impact the conclusions of the risk assessment.

1163-19-5	PBDE #209	7.0E-04	1	7.0E-04	Suggestive evidence of carcinogenic potential

Notes

a COPCs listed in table are PBDE congeners analyzed and detected in the BHHRA dataset, as described in Attachment F3.

b Retrieved from the EPA's IRIS database (February 2011).

c The value presented for the PBDE oral absorption efficiency for dermal is consistent with Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
