Exposure Point Total										6E-13							0.000006

**Notes:**

a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.

b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
CDI = Chronic Daily Intake.  
EPC = Exposure Point Concentration.  
HQ = Hazard Quotient.  
LADI = Lifetime Average Daily Intake.  
mg/kg = milligrams per kilogram.

RfD = Reference dose.  
RM = River mile.  
ug/kg = micrograms per kilogram.

**Notes:**

- a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
- b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

- = Not Applicable.
- CDI = Chronic Daily Intake.
- EPC = Exposure Point Concentration.
- HQ = Hazard Quotient.
- LADI = Lifetime Average Daily Intake.
- mg/kg = milligrams per kilogram.
- RfD = Reference dose.
- RM = River mile.
- ug/kg = micrograms per kilogram.

**Notes:**

a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.

b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
CDI = Chronic Daily Intake.  
EPC = Exposure Point Concentration.  
HQ = Hazard Quotient.  
LADI = Lifetime Average Daily Intake.  
mg/kg = milligrams per kilogram.

RfD = Reference dose.  
RM = River mile.  
ug/kg = micrograms per kilogram.

Exposure Point Total										3E-13							0.000001

**Notes:**

- a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
- b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

- = Not Applicable.
- CDI = Chronic Daily Intake.
- EPC = Exposure Point Concentration.
- HQ = Hazard Quotient.
- LADI = Lifetime Average Daily Intake.
- mg/kg = milligrams per kilogram.
- RfD = Reference dose.
- RM = River mile.
- ug/kg = micrograms per kilogram.

Exposure Point Total										3E-12							0.00001

**Notes:**

a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.

b Study Area wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
CDI = Chronic Daily Intake.  
EPC = Exposure Point Concentration.  
HQ = Hazard Quotient.  
LADI = Lifetime Average Daily Intake.  
mg/kg = milligrams per kilogram.

RfD = Reference dose.  
RM = River mile.  
ug/kg = micrograms per kilogram.

**Notes:**

- a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
- b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
 CDI = Chronic Daily Intake.  
 EPC = Exposure Point Concentration.  
 HQ = Hazard Quotient.  
 LADI = Lifetime Average Daily Intake.  
 mg/kg = milligrams per kilogram.

RfD = Reference dose.  
 RM = River mile.  
 ug/kg = micrograms per kilogram.

Exposure Point Total										2E-12							0.000007

**Notes:**

a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.

b Study Area wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
CDI = Chronic Daily Intake.  
EPC = Exposure Point Concentration.  
HQ = Hazard Quotient.  
LADI = Lifetime Average Daily Intake.  
mg/kg = milligrams per kilogram.

RfD = Reference dose.  
RM = River mile.  
ug/kg = micrograms per kilogram.

**TABLE F3-13.**  
**Calculation of Cancer Risks and Noncancer Hazards - Low-Frequency Fisher, In-water Sediment Exposure**  
**Central Tendency Exposure**

Scenario Timeframe: Current/Future  
Receptor Population: Low frequency Fisher  
Population Age: Adult

Medium: Sediment  
Exposure Medium: In-water Sediment  
Exposure Route: Direct Contact

**Notes:**

a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.

b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
CDI = Chronic Daily Intake.  
EPC = Exposure Point Concentration.  
HQ = Hazard Quotient.  
LADI = Lifetime Average Daily Intake.  
mg/kg = milligrams per kilogram.

RfD = Reference dose.  
RM = River mile.  
ug/kg = micrograms per kilogram.

**Notes:**

a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.

b Study Area wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

-- = Not Applicable.  
CDI = Chronic Daily Intake.  
EPC = Exposure Point Concentration.  
HQ = Hazard Quotient.  
LADI = Lifetime Average Daily Intake.  
mg/kg = milligrams per kilogram.

RfD = Reference dose.  
RM = River mile.  
ug/kg = micrograms per kilogram.

Exposure Point Total										2E-14							0.0000004

**Notes:**

- a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
- b Study Area-wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

- = Not Applicable.
- CDI = Chronic Daily Intake.
- EPC = Exposure Point Concentration.
- HQ = Hazard Quotient.
- LADI = Lifetime Average Daily Intake.
- mg/kg = milligrams per kilogram.
- ND = Not Detected in given exposure area.
- RfD = Reference dose.
- RM = River mile.
- ug/kg = micrograms per kilogram.

**Notes:**

- a Numbers presented are rounded values. Sums calculated before rounding. Risks and hazards are calculated based on exposure parameters presented in Section 3 of Appendix F. For risks and hazards from dermal contact, a dermal absorption efficiency of 0.1 was used, which is the dermal absorption efficiency presented for semi-volatile organic compounds in Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004. EPA/540/R/99/005.
- b Study Area wide dataset includes human health in-water sediment samples from RM 1.9 - 11.8 outside of the navigation channel and excluding Multnomah Channel.

**Abbreviations:**

- = Not Applicable.
- CDI = Chronic Daily Intake.
- EPC = Exposure Point Concentration.
- HQ = Hazard Quotient.
- LADI = Lifetime Average Daily Intake.
- mg/kg = milligrams per kilogram.
- RfD = Reference dose.
- RM = River mile.
- ug/kg = micrograms per kilogram.

Appendix G	Detailed Analysis Cost Estimate
Appendix J	Calculation of Residual and Post Construction Risk Estimates
Appendix K	Surface Water Evaluation
Appendix P	Flood Rise Evaluation

## Introduction to Appendix IV

Appendix IV provides supporting information for the detailed analysis of Alternative F Modified (F Mod). Tables and figures presented herein correlate to FS figures and tables revised to include data for Alternative F Mod. Where possible, FS figure and table numbers were used to title the updated versions presented herein.

It is important to note that specific values such as residual risk and surface water results updated in this appendix (Appendix IV) and presented in the ROD are not directly comparable with those found in the FS. This is the result of two revisions. First, the immediate ( $t=0$ ) pollutant removal effectiveness of enhanced natural recovery (ENR) was assumed to be zero in the FS, but was increased to 97.5% in the ROD. The rationale for this revision is based on further evaluation of post-remediation sediment concentrations assumed at other sites, which are wide ranging, but overall account for some percentage of reduction in sediment concentrations after remediation. While a reduction assumption of 97.5% may be considered at the higher range of post-remedial sediment concentration reduction, the sensitivity of this assumption was evaluated and considered having minimal influence on the alternatives evaluated due to the limited amount of ENR applied site wide. Additional post-remediation sediment concentrations assumed for the evaluation of alternatives are presented in **Attachment A** to this document (Appendix IV). Second, SWACs were computed differently between the ROD and the FS. In the FS, the SWAC values were based on the 95% UCL of the mean, and the mean was the simple average SWACs of the 27 subareas delineated in the statistical analysis presented in Appendix I of the FS. In the ROD, the SWACs are based on the simple average concentrations of each pixel over the entire Site-wide area. The reason EPA made these revisions was to respond to several comments related to the methodology used to calculate SWACs presented in FS Appendix J, which indicated that the basis for the calculations were not transparent and appeared to be inconsistent with other assumptions presented in the FS. Therefore, the updated method is based on an approach that is easier to reproduce and is consistent with other FS elements.

## 4.2 Detailed Analysis of Remedial Alternatives

### 4.2.5 Alternative F Modified (F Mod)

Alternative F Modified (F Mod) uses the RALs presented in Table 18 in Appendix II to develop the combination of remedial technologies applied at the Site. This alternative would support DMM Scenario 2 – off-site disposal.

Alternative F Mod would have a total constructed area of 394 acres of sediment and 23,305 lineal ft of river bank, would allow 1,774 acres of sediment to naturally recover, and would not address 6,744 lineal ft of known contaminated river bank.

This alternative would include capping and dredging 365.3 acres of contaminated sediment and 28.2 acres of ENR. Additionally, 23,305 lineal ft of river bank would be assumed to be appropriately sloped and covered with either a significantly augmented reactive cap or an engineered cap using beach mix or vegetation.

#### *Site Wide*

- Dredging (varying depths): 342.4 acres – 2,481,000 to 3,308,000 cy of sediment
- Excavation: 123,000 cy of soil
- Capping area: 117.8 acres
- Ex-situ treatment: 156,000 to 208,000 cy of sediment and 9,500 cy soil of soil
- In-situ treatment: 0 acres
- ENR: 28.2 acres
- MNR: 1,774 acres

The design concept for Alternative F Mod is shown on Figure 31(a) through (e) in Appendix I.

Construction Duration: Alternative F Mod would take an estimated 13 years of construction, with no additional time required to complete processing of dredged material (i.e., dewatering and sampling for disposal parameters). The estimated schedule would be as follows:

- Year 0: Establish initial conditions
- Year 0: Construction of on-site material handling/treatment facility (if applicable)
- Year 0: Start-up activities and mobilization, including pre-design investigations
- Years 1 through 11: In-river construction
- Year 12: Demobilization and mitigation

Disposal: The material removed from the Site under Alternative F Mod would be managed in the following disposal scenario:

- DMM Scenario 2: 2,481,000 to 3,308,000 cy to off-site disposal facilities in compliance with the off-site rule

ICs and monitoring as described in Section 10.1.1, Common Elements of the Alternatives, would be implemented under this alternative. The key ARARs associated with this alternative are also provided in Common Elements of the Alternatives.

#### **4.2.5.1 Overall Protection of Human Health and the Environment**

Alternative F Mod is expected to be protective of human health and the environment since the postconstruction risks are at or below the interim targets in the majority of the Site and therefore MNR is likely to achieve PRGs within a reasonable time frame. A discussion of how Alternative F Mod performs relative to the interim targets is presented below. An uncertainty analysis (FS Appendix I) was not performed for Alternative F Mod because it is not substantially different from Alternative F in all areas of the Site except the navigation channel. Therefore, it is expected that an uncertainty analysis would be similar to Alternative F and would show that Alternative F Mod would be expected to be statistically distinguishable from the No Action alternative and would provide environmental benefit.

##### RAO 1

The post-construction carcinogenic risks are estimated to be no higher than  $1.0 \times 10^{-5}$  (Appendix IV Figure 4.2-1a-c). Residual risk estimates are based on direct contact exposure to shallow sediments. There is insufficient data to estimate post construction risks based on exposure to beach sediments.

##### RAO 2

The estimated post-construction risk is  $1 \times 10^{-4}$  on a Site-wide scale (Appendix IV Figure 4.2-2). On a river mile scale, post-construction risks are no higher than  $2 \times 10^{-4}$  (Appendix IV Figure 4.2-3a-d and Table J2.3-6a). The highest post-construction risk on an SDU scale is  $2 \times 10^{-4}$  (Appendix IV Table 4.2-1 and Table 4.2-1). The post-construction HI is 15 when evaluated Site-wide, which is greater than the interim target of 10 (Appendix IV Figure 4.2-4). The post-construction HI for infants is 259 on a Site-wide scale (Appendix IV Figure 4.2-6), which is less than the Site-wide interim target of 1,320.

Fish consumption advisories would be required until such time as RAO 2 is achieved. Outreach would be conducted to educate the public about the fish consumption advisories. Informational materials will be needed and evaluated to determine advisory effectiveness.

##### RAO 3

After construction of Alternative F Mod, all surface water COC concentrations achieve the interim target of 10 times the PRG (Appendix IV Figures 4.2-8a-f).

##### RAO 4

Alternative F Mod addresses 39 percent of the river bottom impacted by groundwater plumes through construction (Appendix IV Figure 4.2-24a and Table 4.2-6); the remainder of the contaminated groundwater would be left to MNA and more dependent on the adequacy of the source control.

#### RAO 5

Alternative F Mod addresses 72 percent of the area that exceeds 10 times the benthic risk value (unacceptable benthic risks) (Appendix IV Figure 4.2-25a and Table 4.2-7), which achieves the interim target of 50 percent.

#### RAO 6

The maximum post-construction HQ for BEHP is 5 (Appendix IV Figures 4.2-9a-e through 4.2-17a-e) on a river mile scale, which is less than the interim target of 10. All postconstruction HQs on an SDU scale achieve the interim target of 10 (Appendix IV Table 4.2-5).

#### RAO 7

There is insufficient surface water data to evaluate the effectiveness of this alternative in meeting the PRGs for BEHP, PAHs and TBT. All other sediment-related PRGs for this RAO are achieved with this alternative. Ethylbenzene is expected to be addressed through RAO 8 and implementation of source control measures.

#### RAO 8

Alternative F Mod addresses 39 percent of the river bottom impacted by groundwater plumes through construction (Appendix IV Figure 4.2-18 and Table 4.2-6); the remainder of the contaminated groundwater would be left to MNA and more dependent on the adequacy of the source control.

#### RAO 9

Alternative F Mod addresses 78 percent of the contaminated river bank through construction (Appendix IV Table 4.2-8); the remainder of the contaminated river bank would be left to no action.

### **4.2.5.2 Compliance with ARARs**

Alternative F Mod is expected to comply with ARARs as described in Section 15.2 of the ROD.

### **4.2.5.3 Long-Term Effectiveness and Permanence**

Alternative F Mod permanently removes approximately 3,017,189 cy of contaminated sediment and river bank soil covering approximately 248 acres of river bottom and 23,305 lineal feet of river bank by dredging or excavating to targeted removal depths. Various caps would be placed over 176 acres of the Site. Residuals from dredging and contaminated areas subject to ENR (approximately 240 acres) would be managed with a thin layer sand cover. After construction is completed, the remediated areas would no longer pose unacceptable risks to humans and the environment. However, 82 percent of the area of contaminated sediment would rely on MNR to achieve PRGs and no action would be taken on 22 percent of contaminated river bank.

### **Magnitude of Residual Risk**

Alternative F Mod addresses the highest contaminant concentrations and would result in reducing the risks posed by the Site as well as the potential for contamination in the Site

sediments to be dispersed to less contaminated areas and downstream to the Columbia River. Reductions in COC concentration and related risks are expected to occur over time.

The magnitude of residual risks for each RAO are as follows:

#### RAO 1

The residual risk from exposure to nearshore sediment once PRGs are achieved is  $1 \times 10^{-5}$ , within EPA's acceptable risk range.

#### RAO 2

The Site-wide risk level associated with PRGs is calculated to be  $8 \times 10^{-5}$  (FS Appendix J Table J1-2). The post-construction risk for Alternative F Mod (excluding other risk reduction methods such as MNR and implementation of institutional controls) is  $1 \times 10^{-4}$  (Appendix IV Figure 4.2-2). On both a river mile and SDU scale, the risk level associated with PRGs is calculated to be  $3 \times 10^{-5}$  (FS Appendix J Table J1-2). The highest post-construction risks on a river mile scale is  $2 \times 10^{-4}$  (Appendix IV Figure 4.2-3a-d and Table J2.3-6a). The highest post-construction risk on an SDU scale is  $2 \times 10^{-4}$  (Appendix IV Table 4.2-1).

The Site-wide HI for the child associated with the PRG is calculated to be 6 (FS Appendix J Table J1-2). The post-construction HI for the child is 15 when evaluated Site-wide (Appendix IV Figure 4.2-4).

The Site-wide HI for the infant exposure associated with the PRG is calculated to be 132 (FS Appendix J Table J1-2). The post-construction HI for the infant exposure is 259 when evaluated Site-wide (Appendix IV Figure 4.2-4).

Further reductions in risk are expected through MNR and implementation of institutional controls, although the timeframe for achieving RAOs is uncertain. Fish consumption advisories would be required until such time as RAO 2 is achieved.

The acceptable consumption rates once the PRGs are attained is 27 eight-ounce fish meals every year based on  $1 \times 10^{-5}$  risk, 30 eight-ounce fish meals every year based on noncancer hazard, and 2 eight-ounce fish meals every year for women who may breastfeed (Appendix IV Table 4.2-2). After construction of Alternative F Mod, the acceptable consumption rate is 16 eight-ounce fish meal every year based on  $1 \times 10^{-5}$  risk (Appendix IV Figure 4.2-2), 14 eight-ounce fish meal every year based on a noncancer hazard (Appendix IV Figure 4.2-4) and 0.9 fish meal every year (9 fish meals/10 years) for women who may breastfeed (Appendix IV Figure 4.2-6). Outreach would be conducted to educate the public about the fish consumption advisories. Informational materials will be needed and evaluated to determine advisory effectiveness.

#### RAO 3

The Site-wide surface water contaminant concentrations from contaminated sediment in the Site is a factor of 10 greater than the PRG for PCBs, a factor of 7 greater than the PRG for Tetrachlorodibenzo-p-dioxin (TCDD) (Appendix IV Figures 4.2-8a-f).

#### RAO 4

Approximately 61 percent of the river bottom impacted by contaminated groundwater plumes would not be addressed by Alternative F Mod (Appendix IV Figure 4.2-24a and Table 4.2-6). Placement of reactive caps in locations of contaminated groundwater flux would reduce the exposure to those contaminants and assist in attainment of RAO 4. Residual risks will remain in areas of contaminated groundwater plumes that are not otherwise addressed by capping, dredging, in-situ treatment and ENR; however, the magnitude residual risk is uncertain because it is likely that not all contaminated pore water will be addressed with this alternative.

#### RAO 5

Approximately 28 percent of the area with unacceptable benthic risks would not be addressed by Alternative F Mod (Appendix IV Table 4.2-7 and Figure 4.2-25a). Further risk reductions are likely to occur over time due to natural recovery processes, but the degree in which these benthic risk areas might recover is uncertain because it is likely that an insufficient amount of the benthic risk areas will be addressed with this alternative.

#### RAO 6

The residual HQ once PRGs are achieved is 1 for each COC. The post-construction HQ on a river mile scale is a factor of 5 greater than the residual HQ estimate for BEHP (Figures 4.2-9a-e through 4.2-17a-e). On an SDU scale, the post-construction HQ varies but the maximum is a factor of 3 greater than the residual HQ estimate for BEHP (Appendix IV Table 4.2-5).

#### RAO 7

There is insufficient surface water data to evaluate the magnitude of residual risk. Since Alternative F Mod focuses on containing or removing the highest contaminant concentrations at the Site through capping, dredging, in-situ treatment and ENR it is expected that this will result reductions in contaminant flux from the surface sediment to the surface water and subsequently surface water and fish tissue concentrations. Residual risks in surface water will remain in areas of contaminated sediment that are not otherwise addressed by capping, dredging, in-situ treatment and ENR; however, the magnitude of residual risk is uncertain because it is likely that contaminated sediments remaining will continue to impact the water column with this alternative.

#### RAO 8

Approximately 61 percent of the river bottom impacted by contaminated groundwater plumes would not be addressed by Alternative F Mod (Appendix IV Figure 4.2-24a and Table 4.2-6). Placement of reactive caps in locations of contaminated groundwater flux would reduce the exposure to those contaminants and assist in attainment of RAO 8. Residual risks will remain in areas of contaminated groundwater plumes that are not otherwise addressed by capping, dredging, in-situ treatment and ENR; however, the magnitude of residual risk is uncertain because it is likely that not all pore water will be addressed with this alternative.

### RAO 9

Approximately 22 percent of contaminated river bank soils would not be addressed by Alternative F Mod (Appendix IV Table 4.2-8). Removal of contaminated river bank materials and placement of either an armored or engineered cap using beach mix or vegetation would reduce exposure and erosion potential; however, the magnitude of residual risk is uncertain because it is likely that not all contaminated river banks will be addressed with this alternative.

#### **Adequacy and Reliability of Engineering and Institutional Controls**

Sediment removal, capping, and thin layer covers are reliable and proven technologies as long as they are designed for the appropriate environmental and anthropogenic conditions. Off-site thermal desorption, solidification/stabilization, and land-based disposal facilities are in operation and have proven to be reliable technologies.

Alternative F Mod would be effective in limiting exposure to risks posed by COCs in the sediments and river bank soils provided the integrity of the caps is maintained. Therefore, the caps would need to be monitored and maintained in perpetuity. Reviews at least every five years, as required, would be necessary to evaluate the effectiveness of any of these alternatives because hazardous substances would remain onsite in concentrations greater than would allow for unrestricted use and unlimited exposure.

Operation and maintenance activities, ICs and long-term monitoring will be implemented to assure protectiveness and reliability of caps and thin layer covers. The following paragraphs further describe how these activities maintain the protectiveness and reliability of these controls:

O&M will be required for material left in place and is expected to include bathymetric surveys and diver performed monitoring at regular intervals to confirm the thickness of capping materials. In addition to regular surveys, supplemental surveys will be performed following episodic natural) and anthropogenic events that have the potential to disturb caps and sand covers.

ICs include governmental controls, proprietary controls and informational devices. The reliability of ICs can be enhanced through activities such as regular inspection of buoys and other devices to delineate regulated navigation areas, administrative procedures and inspections to ensure the maintenance of collocated structures and ongoing public outreach efforts to enhance the effectiveness of informational devices. Coordination will need to occur with federal and state regulatory authorities during future permitting activities that are expected to disturb subsurface contaminated sediment or capped areas. Additional institutional controls (see FS Table 2.4-2) would be necessary to maintain cap integrity in perpetuity. Fish consumption advisories, which rely on voluntary compliance, would be enhanced by additional outreach to improve their effectiveness in reducing risk to human health by limiting exposure to COCs.

Monitoring of the effectiveness of the remedial alternative would include sampling of the water column, sediment, pore water, and biota tissue before, during and after construction to verify that

risks to the ecosystem continue to decrease. The planned post-construction monitoring program would result in collection of the data necessary to determine whether the fish consumption advisory or other restrictions imposed as part of the remedial action could be relaxed. Tissue PRGs will be used during the post-construction monitoring period to evaluate if contaminant concentrations are decreasing toward PRGs as expected.

#### **4.2.5.4 Reduction in Toxicity, Mobility and Volume through Treatment**

Implementation of Alternative F Mod reduces toxicity, mobility and volume through treating sediments and river banks where PTW is present or where groundwater plumes are discharging or have the potential to discharge into the sediment and surface water. PTW will be treated in-situ or ex-situ, depending on the technology assignment, while in-situ treatment will be used in areas where groundwater plumes are located.

##### **Treatment Processes Used**

Activated carbon or organophilic clay are the representative in-situ treatment technologies that reduce the bioavailable fractions and thus toxicity and mobility of contaminants as measured through pore water concentrations. The delivery mechanisms for activated carbon or organophilic clay include:

- Broadcast Activated Carbon: Direct broadcasting of 12-inches sand mixed with 5 percent activated carbon (0.12 pounds per square foot per centimeter [lbs/ft<sup>2</sup>/cm])
- Reactive Caps: Includes a 12-inch chemical isolation layer comprised of sand mixed with 5 percent activated carbon (0.12 lbs/ft<sup>2</sup>/cm)
- Reactive Residual Layer: 12 inches of sand mixed with 5 percent activated carbon (0.12 lbs/ft<sup>2</sup>/cm)
- Significantly Augmented Reactive Cap: Includes a 1-inch organoclay mat

PTW that is highly mobile and not reliably contained (NRC) is identified to be treated ex-situ prior to disposal; however, ex-situ treatment of PTW is assumed only to the extent that it is required by the disposal facility. All PTW treated ex-situ under Alternative F Mod is assumed to be disposed at a RCRA Subtitle C facility. In addition, the Subtitle C disposal facility selected as a representative process option (Chem Waste) uses treatment processes such as cement stabilization or thermal desorption, as needed, to meet LDRs for hazardous waste.

##### **Amount of Material Destroyed or Treated**

Under Alternative F Mod, 133 acres of material are assumed to be treated in-situ (includes broadcast activated carbon, reactive caps, reactive residual layers and significantly augmented reactive caps) and 192,000 cy of material would be treated ex-situ.

### **Reduction of Toxicity, Mobility or Volume**

Reduction of toxicity, mobility and volume would be achieved through:

- Broadcast Activated Carbon: 0 acres
- Reactive Caps: 83.2 acres
- Reactive Residual Layer: 45.9 acres
- Significantly Augmented Reactive Cap: 3.7 acres

In addition, based on the technology assignments for Alternative F Mod, the quantity of dredged PTW (source material and not reliably contained) requiring ex-situ treatment is estimated at 192,000 cy. The actual amount of material subject to ex-situ treatment would depend on the results of the waste characterization testing during the remedial design. Thermal desorption reduces the mobility of approximately 39 percent of the dredged material that is PTW NRC/NAPL where stabilization/solidification would reduce the mobility most of this material. In addition, the mobility of contaminants would be further reduced through sequestration by placing it in a permitted landfill, not due to permanent and irreversible treatment.

For dredged material not subject to ex-situ treatment, mobility would be reduced by placing it into a permitted landfill (through sequestration, not treatment); there would be no reduction in toxicity or volume.

### **Irreversible Treatment**

Activated carbon is not readily broken down in the environment and thermodynamic principles indicate that the bonding of COCs to activated carbon will remain strong over time. COCs are expected to remain bound whether the sorbent and bound chemicals remain in the sediment bed or are re-suspended and transported away from the area (ITRC 2014). As a result, use of activated carbon for in-situ treatment is considered permanent and irreversible as long as there is sufficient quantity of activated carbon to address the amount of contamination present.

Low-Temperature Thermal Desorption is an ex-situ remedial technology that uses heat to physically separate organic contaminants from excavated soils and sediments. Thermal desorbers are designed to heat contaminated sediments to temperatures sufficient to cause contaminants to volatilize and desorb (physically separate) from the sediment. Although they are not designed to decompose organic constituents, thermal desorbers can, depending upon the specific organics present and the temperature of the desorber system, cause some of the contaminants to completely or partially decompose. The vaporized hydrocarbons are generally treated in a secondary treatment unit (such as an afterburner, catalytic oxidation chamber, condenser, or carbon adsorption unit) prior to discharge to the atmosphere. Afterburners and oxidizers destroy the organic constituents. Condensers and carbon adsorption units trap organic compounds for subsequent treatment or disposal.

Solidification/Stabilization adds chemically reactive compounds to dredge materials that form stable solids that are non-hazardous or less-hazardous than the original materials. Solidification

refers to the physical changes in the contaminated material when a certain binding agent is added. These changes include an increase in compressive strength, a decrease in permeability, and condensing of hazardous materials. Stabilization refers to the chemical changes between the stabilizing agent (binding agent) and the hazardous constituent. These changes result in a less soluble, less toxic material with reduced mobility. Common bonding agents include, but are not limited to, Portland cement, lime, limestone, fly ash, slag, clay, and gypsum. Because of the vast types of hazardous materials, each agent should be tested/piloted at the Site before a full-scale project is undertaken. Most binding agents used are a blend of various single binding agents, depending on the hazardous material. Portland cement has been used to treat more contaminated material than any other solidification/stabilization binding agent because of its ability to bind free liquids, reduce permeability, encapsulate hazardous materials, and reduce the toxicity of certain contaminants. Lime can be used to adjust the pH of the substance of drive off water by the exo-thermic reaction. Limestone can also be used to adjust pH levels.

### **Type and Quantity of Residuals Remaining After Treatment**

Implementation of Alternative F Mod address all of the PTW at the Site. Therefore, this alternative meets the NCP expectation for addressing all principal threat wastes to the maximum extent practicable. While 83.2 acres of reactive caps are included in this alternative to deal with exposures from contaminated groundwater plumes, the full extent of exposure from these plumes is uncertain and has not been quantified. Based on the upland evaluations on the nature and extent of these groundwater plumes, this alternative would treat approximately 39 percent of contaminated groundwater discharging to the sediment bed within the Site. Additional characterization during remedial design would be required to ensure that the full extent of the exposure is addressed in remedy implementation.

#### **4.2.5.5 Short-Term Effectiveness**

Implementation of Alternative F Mod would have some impact to the community, workers, and the environment during construction. The period of construction is estimated as 4 months per year for 13 years. During the construction period, approximately 3,017,189 cy dredged sediment and excavated soil would be transported off the Site and 1,339,587 cy capping and residual management materials would be transported into the Site. Dredged materials and capping and residual management materials will need to be handled by workers. Impacts to the environment would occur during construction and continue until RAOs are achieved. These impacts would include unacceptable human and ecological exposure as well as reducing the ability for humans to safely consume fish and the ability of the tribes to fully engage in their ceremonial practices, which involve fish consumption. Impacts to the aquatic environment for are also described further in FS Appendix L.

### **Community Protection**

There are some short-term risks to the community from exposure to contaminated sediments and river bank soils during the construction period. This alternative involves dredging of 248 acres and excavation of 23,305 lineal feet of river bank, with import of approximately 1,339,587 cy of

capping and residual management material. Construction is assumed to proceed continuously for 24 hours per day, six days per week, 122 days per year, and for 13 years. Construction and operation of a treatment and transport facility should be necessary. Construction and operation activities is expected to result in temporary noise, light, odors, potential air quality impacts and disruptions to commercial and recreational river users on both sides of the river. However, the actual duration at any specific location would be less than the overall construction period.

Material transported off-site for disposal is assumed to be conducted via barge to an offsite transloading facility and then trucked or railed to the disposal facility. Increased barge traffic transporting dredged material will likely interfere with commercial navigation, with increased potential for waterborne accidents and on-shore impacts from exhaust. If an on-site transloading facility were constructed, off-site disposal is expected to result in upland impacts to the community through increased vehicular traffic (direct transport to off-site disposal or rail transfer facilities) with potential increases in accidents and air-quality issues associated with dust, odor, and vehicular exhaust. Under Alternative F Mod, the capping and residual management materials for construction would require handling and transport through the community and would have impacts similar to those described for off-site disposal.

Measures to minimize short-term risks to the community will be addressed through implementation of health and safety plans and the use of BMPs, including but not limited to, the following:

- Limiting access to sediment processing at upland treatment and transfer facility areas to authorized and trained personnel.
- Pollution controls to minimize emissions and odors from construction activities.
- Engineering and navigation controls (established by the dredging and/or materials management contractor working in coordination with the U.S. Coast Guard and other entities) to mitigate increased river traffic.
- Isolating work areas with an adequate buffer zone so that pleasure craft and commercial shipping can safely avoid construction areas.
- Fish consumption advisories would continue under this alternative until such time as RAOs are achieved. COC concentrations in fish tissue are expected to increase during the course of the multi-year construction period; however, this will mainly occur during the in-river work window of July 1 through October 31. Based on experience at other sites [Hudson River (NY), Grasse River (NY)], recovery following construction is relatively rapid, on the order of a few years, and is expected to continue to decrease as contaminant concentrations in sediment decrease.

### **Worker Protection**

Alternative F Mod would pose potential risks to Site workers through:

- Direct contact with COCs in dredged sediment
- Demolition, removal, and/or replacement of structures
- Activities in a river environment such as working on a vessel, near heavy and mobile equipment in and around working docks
- Working around marine operations with frequent vessel traffic
- Transport of borrow materials and carbon amendment for cover construction
- Placing amendments in in-situ treatment areas
- Transport of contaminated sediment and river bank soils

Safety measures and BMPs would be used to minimize the impacts referenced above. Measures such as:

- Use personal protective equipment (PPE)
- Establish work zones
- Dust suppression during material handling and river bank actions
- Worker Health and Safety Plans
- Following Occupational Safety and Health Administration (OSHA) approved health and safety procedures

### **Environmental Impacts**

Sediment removal and capping is expected to result in short-term adverse impacts to the river, including:

- Exposure of fish and other biota to suspended and dissolved contaminants or material in the water column
- Temporary loss of benthos and habitat for the ecological community in dredged areas
- Increased emissions from construction and transportation equipment

Measures and BMPs would be used to minimize the above referenced impacts, including:

- Engineering controls to minimize resuspension/release during cap placement
- Sequencing of dredging and placement activities to minimize recontamination potential
- Conduct work within the in-river work window (July 1st through October 31st) to minimize impacts to migratory fish
- Silt curtains, sheet pile walls, or other physical barriers will be used as appropriate to minimize releases
- Actions will be taken to remove fish from within barrier enclosures prior to commencing construction activities

Precautions and controls will be taken to prevent incidental and accidental discharges of toxic materials from entering the water column from in-river work. These include:

- Use spill plates and aprons to prevent dropping dredge material into the water
- Reduction of cycle times
- Restrict lateral movement of the dredge bucket while under water
- Use closed dredge buckets whenever Site conditions allow
- Reduce or stop dredging during periods of peak current

Application of BMPs for emissions reduction would reduce short-term impacts posed to the environment and would be consistent with the EPA Region 10 Clean and Green Policy. A Green Remediation Plan will be required during remedial design consistent with the outline provided in FS Appendix M. Emission reduction could be controlled through BMPs such as:

- Use of reusable energy sources.
- Limit idling of trucks and equipment.
- Rely on local sources of materials.
- Ensuring that trucks, barges and railcars are full prior to transport
- Implement onsite dust and noise control to reduce air pollutant and greenhouse gas emissions.
- Require clean fuel incentives in construction contracts.

Environmental impacts would continue until RAOs are achieved. Environmental impacts to human health via consumption would be controlled through fish consumption advisories.

#### **Time until Action Complete**

Construction operations for this alternative are estimated to take 13 years.

#### **4.2.5.6 Implementability**

Alternative F Mod would be implementable from both the technical and administrative standpoints given the considerations described in the following paragraphs.

#### **Ability to Construct and Operate**

The in-river construction activities required for the implementation of Alternative F Mod would be technically feasible and have been implemented at many Superfund sites around the country. Implementation of Alternative F Mod would involve dredging and excavating approximately 3,017,189 cy of contaminated material and the handling and placement of 1,339,587 cy capping and residual management material.

Alternative F Mod has a construction period of approximately 13 years, involves construction activities within 394 acres. Portland Harbor is a working industrial waterway that has the necessary infrastructure to support sediment remediation activities. Nevertheless, careful coordination will be required among government agencies, private entities and the community to

design, schedule, and construct the cleanup actions. Further, it will be important to evaluate whether upland source control actions have been implemented to a sufficient degree before or as a part of remedy construction to limit recontamination potential.<sup>1</sup>

Inadequate removal of contaminated sediment and soil or the need to manage residuals remaining after dredging or excavating could require further evaluation to determine the need for additional actions. Construction and reliable operation of release and residual management measures such as silt curtains and sheet piles will increase in difficulty in portions of the river affected by navigation traffic, deeper water, and significant current, and will lead to increased schedule and implementation delays.

Another technical implementability challenge is remediation under and behind piers and other above-water structures. Debris is expected to complicate, but is not likely to significantly delay, construction efforts. Maintaining flexibility in construction methods through the remedial design phase is an important consideration for these areas.

#### **Ease of Doing More Action, if Needed**

Increasing the extent of capping, dredging/excavation, in-situ treatment, or ENR would be easily implemented. Additional remedial actions on river banks could be more problematic due to factors such as adjacent land use, structures, steepness, use of the adjacent waterways, and community concerns. Depending on the scope of the additional actions, post-ROD changes will likely be needed.

#### **Ability to Monitor Effectiveness**

Monitoring of the effectiveness of the remedial alternative would include sampling of the water column, sediment, pore water, and biota tissue before, during and after construction to verify that risks to the ecosystem continue to decrease. Fish consumption advisories would be required until such time as RAO 2 is achieved. Outreach would be conducted to educate the public about the fish consumption advisories. Informational materials will be needed and evaluated to determine advisory effectiveness.

RNAs are assumed for 150 acres of caps. Regular monitoring of cap performance would be conducted and evaluated on 176 acres of caps required under 5-year reviews. Inspection, maintenance, and repair/replacement of caps are relatively easy and straightforward to implement in unobstructed areas, but are expected to be more challenging around obstructions, in the navigation channel, or in future maintenance dredge areas. If monitoring should fail to detect in a reasonable time frame a release in areas where waste has been left in place, then an unacceptable release of COCs to the environment will likely occur.

---

<sup>1</sup> If further action under CERCLA is warranted, then a separate decision document would be issued.

Alternative F Mod relies on reducing contaminant concentrations through MNR for approximately 1,774 acres. MNR requires significant administrative effort over the long term to oversee and coordinate sampling, data evaluation, and future additional actions, if any are needed. The MNR analysis conducted in FS Appendix D.8 indicates that the majority of the site is neutral (transitional); therefore, there is greater uncertainty that RAOs will be achieved in a reasonable timeframe due to the remaining concentrations. For this reason, some additional future remedial actions are predicted to be more likely for Alternative F Mod. Should future remedial actions be warranted, subsequent decision documents would be issued.

#### **Ability to Obtain Approvals and Coordinate with Other Agencies**

Coordination with the ODFW, NMFS, and USF&W would need to be conducted during construction in order to protect migrating salmon in the lower Willamette River. The current in-river fish work window established for the Willamette River is July 1 through October 31 and accounts for fish migration patterns. Extending the period of the work each year would require consultation with ODFW, NMFS, and USF&W, but should be obtainable.

Coordination with DSL and/or other property owners would need to be conducted to manage waste left in place and implement land use restriction ICs, if needed. Additionally, property owners of potential staging areas and transloading facilities would also need to be consulted and access obtained. Alternative F Mod leaves waste in place in 1,920 acres of the Site.

Regulatory approval for off-site permitted disposal facilities as identified in FS Table 2.4-2 should be readily obtainable.

Coordination with DSL and/or other property owners would need to be conducted for demolition and removal, or relocation of structures are expected to be challenging, but should be obtainable.

Institutional controls, such as RNAs or other land use restriction mechanism, would need to be established for all in-river caps. Under Alternative F Mod, 150 acres of caps are assumed to need RNAs and 176 acres of caps are assumed to need land use restrictions. These ICs should be straightforward and easily obtainable.

Coordination with ODFW, NMFS, and USF&W would need to be conducted during construction in order to determine mitigation requirements under CWA 404 and ESA. Onsite identification of mitigation sites will likely be difficult to attain due to the lack of available locations within the Site and current and or future land uses. Off-site mitigation, if required, would need regulatory approvals which could likely take longer than on-site mitigation. Implementation of mitigation should be straightforward. Under Alternative F Mod, it is estimated that 60 acres for costing purposes would require some type of mitigation.

### **Availability of Adequate Off-site Treatment, Storage Capacity, and Disposal Capacity and Services**

Regional upland landfills are authorized to receive contaminated sediment and have done so on several recent projects in or near the Site. Upland commercial landfills are identified in FS Table 2.4-2 have capacity relative to the volume of sediment expected to be dredged from the Site for Alternative F Mod. The upland commercial landfills can accept wastes transported by rail, barge, or trucking. Transportation and management of materials would involve identification of sufficient space and proximity to the transportation network to the landfill facility. Several potential sites were identified in the Portland Harbor area where transload facility exists for handling material for disposal in an upland commercial landfill (FS Appendix F).

### **Availability of Specialists, Equipment and Materials**

Services, equipment, and materials are locally or regionally available. Experienced environmental dredge and excavator operators, and material placement specialists would be required. Three dredges are assumed for Alternative F Mod. Modes of transporting material offsite include barging to existing transloading facilities and transporting to an off-site disposal facility via truck or rail. Approximately 1,985 barge loads and 198,615 truckloads or 49,606 rail loads are assumed to transport the removed material. If an onsite transloading facility were constructed, approximately the same number of truckloads and/or rail loads are assumed for off-site disposal. Additionally, 941 barge loads, 116,829 truckloads, or 24,258 rail loads are assumed to transport material into the Site. Columbia River dredge material is a potential source of capping and residual management material, if it meets the clean fill requirements specified in the ROD.

### **Availability of Technologies**

Technologies specific to dredging, capping, and on-site treatment are available and have been previously used at the Site for early actions.

#### **4.2.5.7 Cost**

Total capital costs estimated for this alternative are \$1,184,607,000 over 13 years. Total periodic costs (including O&M) are \$524,028,000; of which the 5-year review periodic costs are \$308,000 per event, totaling \$1,848,000 over 30 years. The total undiscounted alternative cost is estimated to be \$1,708,635,000, with a net present value cost of \$1,054,200,000. Detailed costs associated with implementing Alternative F Mod are presented in Appendix IV.

**Attachment A**  
**Post-Remediation Sediment Concentration Assumptions**

**ESTIMATE OF POST-REMEDICATION SEDIMENT CONCENTRATIONS:**

For the purposes of evaluating long term effectiveness and permanence and overall protection of human health and the environment in the feasibility study, estimates of post remediation sediment concentrations are required. Technology assignments used to develop remedial action alternatives include dredging, capping, in-situ treatment, ENR and MNR alone or in combination. Specific technology assignments used to develop remedial action alternatives are listed below:

- Broadcast GAC (Aquablock or equivalent)
- Engineered cap (3ft)
- Cap with armoring (3ft)
- Reactive armored cap (3ft)
- Reactive cap (3ft)
- Dredge with backfill
- Dredge with engineered cap (3ft)
- Dredge with reactive armored cap (3ft)
- Dredge with reactive cap (3ft)
- Dredge with reactive cap (3ft)
- Dredge with residual layer (1ft)
- Dredge with reactive residual layer (1ft)
- Dredge with reactive residual layer (1ft) and backfill
- Dredge with significantly augmented reactive cap (3ft)
- Dredge with significantly augmented reactive cap (3ft)
- ENR in Swan Island
- MNR
- MNR - No tech assigned
- Previously remediated

Post remediation sediment concentrations were estimated based on specific technology assignments:

- **Removal Based Technologies:** Post remediation sediment concentrations for removal based technologies are a function of the residual management layer placed following completion of dredging or excavation. Residual management layers include capping, backfill to grade and placement of thin layer sand covers. For each of these technologies, initial sediment concentrations are assumed to be zero following placement of the clean cap, backfill, or sand layer. For placement of thin layer sand covers as a residual management layer, the feasibility study assumed that the 12-inch thin layer sand cover in conjunction with the dredging best management practices described in the FS will be sufficient to minimize the potential for contamination at the surface of the residual management layer following placement. Therefore, the surface sediment concentration is assumed to be zero.

- Capping Based Technologies: Capping based technologies include conventional sand caps, armored caps and reactive caps alone or in combination. In addition, caps may be placed following dredging activities. For all capping based technologies including caps placed post dredging, the feasibility study assumes that sediment concentrations will be reduced by 100 percent to an initial sediment concentration of zero. Although it is recognized that recontamination from adjacent and upstream sediments will occur following placement of the cap material, this feasibility study does not consider this process for the purpose of evaluating remedial action alternatives.
- In-situ Treatment: A literature review suggests that activated carbon can reduce the bioavailable fraction of PCBs, PAHs, and 4,4'- DDT as measured through porewater concentrations by 90 percent (Ghosh et al. 2011; Tomaszewski et al. 2008; Zimmerman et al. 2005). For the purpose of the feasibility study, in-situ treatment is expected to be accomplished through placement of a 12-inch sand layer including enough reactive material to achieve 5 percent by weight GAC. Because further reductions in contaminant concentration through placement of the sand layer are expected, it is assumed that in-situ treatment will reduce surface sediment concentrations to zero using the same assumptions as described above for the post dredging thin layer sand cover.
- ENR: ENR is assumed to be accomplished through placement of a 12-inch thin layer ENR sand cover. Post remedy surface sediment concentrations are assumed to be reduced by 97.5 percent. The 97.5% reduction assumes that limited mixing of the 12-inch ENR layer will occur.
- MNR: No reduction in sediment concentration is assumed from monitored natural recovery.

A summary of the post remedial sediment concentrations is presented in Table 1.

There is uncertainty associated with the development of post remediation sediment concentrations all technology assignments. Key uncertainties include:

- Uncertainty in the dredged residual surface sediment concentration due uncertainties in the vertical sediment concentration profile;
- Uncertainty in the concentration of backfill material used as post dredging residual layer prior to and following placement;
- Uncertainty in the concentration of the capping material prior to and following placement; and
- Uncertainty in the recontamination potential associated with unremediated sediments adjacent to the remediated area.

Post remediation sediment concentration estimates were developed on a surface weighted average concentration (SWAC) basis. The SWAC was estimated on a RAO basis. The RAO determined the spatial scale over which the SWAC was estimated as summarized below:

- RAO 1 - Direct Contact Human Health: Risk reduction was evaluated on a one-mile exposure scale based on rolling river miles (e.g., RM 3.1 – 4.1, RM 3.2 – 4.2, RM 3.3 – 4.3, etc.) for both the east and west nearshore areas along with Swan Island Lagoon.
- RAO 2 – Fish Consumption Human Health: Risk reduction was evaluated on a one-mile exposure scale based on rolling river miles (e.g., RM 3.1 – 4.1, RM 3.2 – 4.2, RM 3.3 – 4.3, etc.) for the east, west, and navigation channel along with Swan Island Lagoon.
- RAO 5 – Direct Contact Ecological Receptors: Risk reduction was evaluated on a 0.2 mile exposure scale based on rolling river miles (e.g., RM 3.2 – 3.4, RM 3.3 – 3.5, RM 3.4 – 3.6, etc.) for the east, west, and navigation channel along with Swan Island Lagoon.
- RAO 6 – Prey Consumption Ecological Receptors: Risk reduction was evaluated on a one-mile exposure scale based on rolling river miles (e.g., RM 3.1 – 4.1, RM 3.2 – 4.2, RM 3.3 – 4.3, etc.) for the east, west, and navigation channel along with Swan Island Lagoon.

In addition to rolling river mile averages for the east side of the river, the west side of the river, the navigation channel and Swan Island Lagoon, risk reduction was also evaluated on a site-wide exposure scale. Results of the risk reduction evaluation are presented in the risk discussions by alternative in ROD Table 22 and updated Section 4.2 for Alt F Modified (ROD, Part II, Appendix IV).

Notes:

1) Neat volumes are multiplied by an overdredge factor of 1.5 to estimate the "Low Volume with Overdredge" and multiplied by an overdredge factor of 2.0 to estimate the "High Volume with Overdredge".

2) Cost information is provided in Appendix G.

3) In-situ treatment quantity includes only those PTW areas outside of sediment management areas (SMAs).

Removal volumes presented in this table are a product of rounded and non-rounded estimates found on Tables 3.8-4 and 3.8-5. Please see the notes under these tables and Appendix D2 for more information.

Notes:

1) Estimated range of volume for alternatives derived by multiplying the “neat” dredge volume by 1.5 for the low range and by 2 for the high range.

2) All material quantities expressed as in-situ, neat measurements.

The quantities presented above are rounded. See Appendix D.2 for additional information.

**Table 3.8-5****Summary of Excavated River Bank Volumes and Material Quantities for each Alternative**

Portland Harbor Superfund Site

Portland, Oregon

Alternative	Total Excavated Volume (cu yd)	Ex-Situ Treatment Volume (cu yd)	Material Volumes for Containment, Dredge Residuals Management, and In-Situ Treatment <sup>1</sup>						
			Sand	Low-Permeability Sand	Beach Mix	Armor	Aquablok	AquaGate + 10% PAC	Organoclay Mats
			(cu yd)				(tons)		
B	51,000	9,500	38,000	4,500	7,000	2,000	0	0	260
C	58,000	9,500	44,000	4,500	8,000	2,000	0	0	260
D	73,000	9,500	56,000	4,500	11,000	2,000	0	0	260
E	96,000	9,500	75,000	4,500	14,000	2,000	0	0	260
F Mod	123,000	9,500	98,000	4,500	19,000	2,000	0	0	260
F	123,000	9,500	98,000	4,500	19,000	2,000	0	0	260
G	139,000	9,500	111,000	4,500	22,000	2,000	0	0	260
H	158,000	9,500	127,000	4,500	25,000	2,000	0	0	260
I	103,000	9,500	81,000	4,500	16,000	2,000	0	0	260

## Notes:

1) All material quantities neat measurements.

The quantities presented above do not come directly from the R code. The lengths of river banks were conservatively estimated using property boundaries and the outer limits of the site boundary. Area calculations were based on simplifying assumptions for bank slope length. Calculations for river banks with full assumptions are presented in Appendix D.

- Acceptable Fish Meals calculated according to the following formula: Acceptable Risk Level/Post Construction Risk x consumption rate (meals/yr).

- Consumption rates utilized are highlighted in green below:

Scenario	Meal Size (ounces)	Consumption Rate	
		g/day	meals/yr
Recreational CTE	8	17.5	28
Recreational RME	8	49	79
Subsistence	8	142	229
Tribal	8	175	282
Child Subsistence	3.5	60	221
OHA advisory	8	7.5	12

- Adult consumption rate in meals per year are based on a 142 g/day fish consumption rate and an 8 ounce fish meal.

- Child consumption rate in meals per year are based on a 60 g/day fish consumption rate and an 3.5 ounce fish meal.

- Acceptable meal rates are based on fish consumption only and do not consider cPAH contamination and shellfish consumption.

## D5. PAH/cPAH CONVERSION

---

PRGs were developed for both total PAHs (ecological risk) and cPAHs (human health risk). A regressions analysis was performed to determine the relationship between total PAHs and cPAHs (as benzo(a)pyrene equivalent [BaP-Eq]). The calculated values for total PAHs and the corresponding cPAHs for each data point were plotted, and a regression line was generated. The results are presented on **Figure D5-1**. Total PAHs are well correlated with cPAHs (adjusted  $R^2 = 0.969$ ) although local variation in the total PAH/cPAH relationship imparts some uncertainty. Therefore, the relationship is defined using the following regression equation:

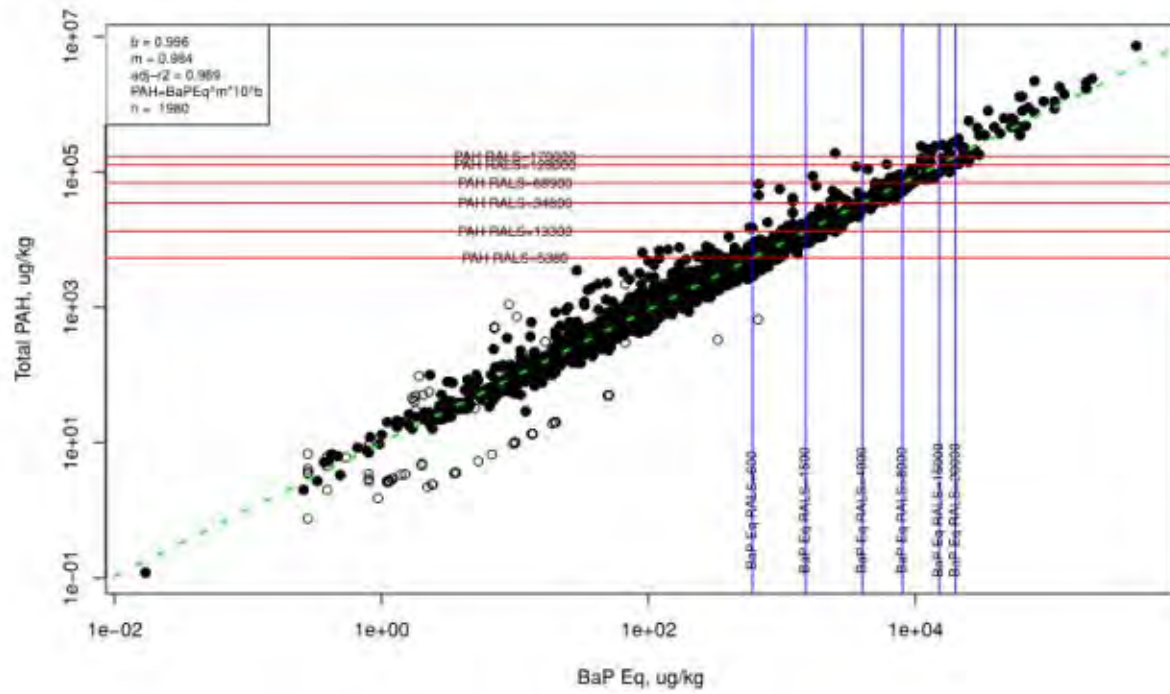

$$TotalPAHs = (BaP - Eq)^m \times 10^b$$

where:

$$m = 0.984 \text{ and } b = 0.996.$$

This relationship was developed based on 1980 measurements. The relationship shows that the Alternative F RAL for total PAHs of 13,000 ug/kg results in a cPAH RAL equivalent of 1500 ug/kg when measured as BaPEq.

Figure D5-1: Total PAH vs BAP Eq Relationship – Sitewide Surface Sediment

## **Tables**

**Table D2.a. In-Water Areas by Technology Assignment**

Portland Harbor Superfund Site  
 Portland, Oregon

**Summary of In-Water Areas by Technology Assignment**

Technology Name	Area (AC)	
		Alt. F Mod
Broadcast GAC (1ft)		NA
Engineered Cap (3ft)		9.53
Armored Cap (3ft)		44.91

**Table D2.b. Riverbank Quantities**

Portland Harbor Superfund Site  
 Portland, Oregon

**Riverbank Assumptions**

- Contaminated riverbanks are pre-determined areas defined as lines along the outer limits of the site boundary and are estimated locations only.
- Riverbank technology assignments were based on adjacent nearshore PTW and RAL areas:
  - Potentially contaminated riverbanks are identified as lines along the shore of the site. Because the riverbank lines do not fall directly on RAL or PTW (NRC or NAPL) area created for the site, a parallel line was created 20 ft into the site area to best estimate the amount of each line that intersects with RAL boundaries and/or PTW (NRC or N boundaries and keep consistent overlap.
  - The parallel line was intersected with RAL boundaries and PTW (NRC and NAPL) boundaries to determine the length of riverbank technology assignments based on the following:
    - Riverbanks adjacent to PTW (NRC or NAPL) areas were assigned excavation and significantly augmented reactive cap (Geofabric, 17" fine-grained low permeability sand organoclay mat, 12" medium sand, and 6" armor stone).
    - Riverbanks adjacent to RAL Boundaries and outside PTW (NRC or NAPL) areas were assigned excavation and engineered cap (Geofabric, 30" sand, and 6" beachmix).
    - Otherwise no action was assigned.
- Based on this intersection some rough linear estimates were given in the following table.
- No action will be taken for the areas adjacent to MNR because it is not considered to be in an SMA.

Technology Name	Length of Riverbank by Tech Assignment (FT)	
	Alt. F Mod	
Excavate with engineered cap (3ft)		21,510.8
Excavate with significantly augmented reactive cap (3ft)		1,794.0
No Action		6,743.5
<b>Grand Total</b>		<b>30,049</b>

Note:

1 - Grand Total above is rounded to the nearest whole number.

**PTW Assumptions**

- The parallel riverbank lines from above were intersected with each of the three types of PTW.
- Not reliably contained PTW was not found within 20 ft of the riverbank areas and no values were obtained. The others are shown in the table below.
- NAPL is the only PTW assumed to be treated and the only one used for calculations

		Length of Riverbank Identified as PTW Excavated (FT)
NRC/NAPL PTW - Area 6W		1,794.0
NRC/NAPL PTW - Area 7W		0.0
<b>Grand Total</b>		<b>1,794</b>

Note:

1 - Grand Total above is rounded to the nearest whole number.

**Riverbank Volume Assumptions for Excavate-Disposal**

Common Earth Conversion from BCY to LCY = 1.12 Means Heavy Construction Handbook

Bank volumes and areas are based on linear feet and the simplified assumptions listed below:

Assumed Bank Slope =	1	V	:	H	3
H (Assumed Bank Height) (FT) =	15				
L (Horizontal distance) (FT) =	45				
Hypotenuse Length of Riverbank Surface (FT) =	47.4				
x (Average Excavation Depth) (FT) =	3				
a (FT) =	9.49				
Area of Excavation Surface (SF) =	142.30

### Table D2.c. Dredge Quantities

Portland Harbor Superfund Site  
 Portland, Oregon

Confined Dredged Volumes (CY)	
Technology Name	Alt. F Mod
Dredge w/Backfill + Beach Mix (6in)	11,224.9
Dredge w/Engineered Cap + Beach Mix (3ft)	2,300.0
Dredge with reactive cap with Beachmix (3ft)	11,377.8
Dredge with residual layer (1ft)	6,318.8
Dredge with reactive residual layer (1ft)	21,422.1
Dredge with reactive residual layer with Beachmix (1ft)	12,278.8
Dredge with significantly augmented reactive cap (3ft)	4,666.7
Dredge with significantly augmented reactive cap with Beachmix (3ft)	833.3
<b>Total Confined Dredged Material (CY)</b>	<b>70,423</b>

Open Water Dredged Volumes (CY)	
Dredge w/Backfill + Beach Mix (6in)	76,788.4
Dredge w/Engineered Cap + Beach Mix (3ft)	50,155.6
Dredge with reactive cap with Beachmix (3ft)	90,200.0
Dredge with residual layer (1ft)	1,015,480.7
Dredge with reactive residual layer (1ft)	282,186.3
Dredge with reactive residual layer with Beachmix (1ft)	61,519.5
Dredge with significantly augmented reactive cap (3ft)	4,055.6
Dredge with significantly augmented reactive cap with Beachmix (3ft)	3,111.1
<b>Total Open Water Dredged Material (CY)</b>	<b>1,583,498</b>

**Notes:**

- 1 - Cells highlighted in Yellow are direct output quantities from R code.
- 2 - Quantities above are considered "neat" with no overdredge allowance. Overdredge factors are incorporated into the following summary calculations.
- 3 - In place and excavated volumes are assumed to be similar because the excavated material will be in a somewhat loose state following dredging.
- 4 - Total quantities are rounded up to nearest whole number.

### Summary of Dredge Volumes

	Alt. F Mod
Total CY Dredged (Open Water) Neat	1,583,498
Low Volume with Overdredge (Open Water)	2,375,247
High Volume with Overdredge (Open Water)	3,166,996
<b>Total Open Water Dredge Volume (CY)</b>	<b>2,771,122</b>
Total CY Dredged (Confined) Neat	70,423
Low Volume with Overdredge (Confined)	105,635
High Volume with Overdredge (Confined)	140,846
<b>Total Confined Dredge Volume (CY)</b>	<b>123,241</b>
Total CY Dredged Neat	1,653,921
Low Volume with Overdredge	2,480,882
High Volume with Overdredge, Total Volume (Overdredge Factor of 2.0)	3,307,842
<b>Total Volume Dredged (CY)</b>	<b>2,894,362</b>

**Notes:**

- 1 - Neat volumes are multiplied by an overdredge factor of 1.5 to estimate the "Low Volume with Overdredge" and multiplied by an overdredge factor of 2.0 to estimate the "High Volume with Overdredge"
- 2 - Dredge Volume Totals represent an average of the estimated Low and High Overdredge Volumes.
- 3 - Quantities with red bold formatting are cost estimate input values.
- 4 - Dredge Volume Totals are rounded up to the nearest whole number.

### Table D2.c. Dredge Quantities (continued)

Portland Harbor Superfund Site  
 Portland, Oregon

#### Dredge and Dewatering Productivity Quantities

Assumed Dredging Productivity (CY/DY): 5100  
 Per dredging productivity assumptions

	Alt. F Mod
Estimated Number of Dredging Days (DY)	568
<b>Estimated Number of Days for Dewatering/Water Treatment Operations (DY)</b>	<b>568</b>
Excavated Volume for Riverbanks (BCY)	122,827
Excavated Volume for Riverbanks (LCY)	137,567

**Notes:**

- 1 - Quantities with red bold formatting are cost estimate input values.
- 2 - Total quantities are rounded up to the nearest whole number.
- 3 - Quantity derivation for the riverbank volumes are presented Table D2.b.

#### Summary of Dredging and Riverbank Excavation Volumes

	Alt. F Mod
Total Dredged Volume (Low Overdredge) (CY)	2,481,000
Total Dredged Volume (High Overdredge) (CY)	3,308,000
Total Dredged Volume (Average) (CY)	2,894,000
Total Riverbank Excavation Volume (CY)	123,000
Total Combined Dredge/Excavation Volume (Low) (CY)	2,604,000
Total Combined Dredge/Excavation Volume (High) (CY)	3,431,000
Total Combined Dredge/Excavation Volume (Average) (CY)	3,017,000

**Notes:**

- 1 - Green bold quantities are presented in ROD Text and Tables.
- 2 - Quantities are rounded to the nearest thousand.

### Table D2.d. Treatment and Disposal Quantities

Portland Harbor Superfund Site  
 Portland, Oregon

#### Treatment and Disposal Assumptions

1. Not Reliably Contained (NRC) / Non Aqueous Phase Liquid (NAPL) Principal Threat Waste (PTW) will be disposed at Subtitle C and everything else will be disposed at a Subtitle D facility
2. For purposes of evaluating cost, ex-situ treatment will be assumed only for NRC/NAPL PTW materials. Ex-situ treatment assumptions differ depending on whether the NRC/NAPL PTW is dredged from Area 6W or Area 7W. The table below summarizes assumptions:

Material	No Treatment
NRC/NAPL PTW - Area 6W	0%
NRC/NAPL PTW - Area 7W	33.33%
All Other Materials	100%

Material	Disposal	
	Subtitle C	Subtitle D
NRC/NAPL PTW - Area 6W	X	
NRC/NAPL PTW - Area 7W	X	
All Other Materials		X

### Table D2.d. Treatment and Disposal Quantities (continued)

Portland Harbor Superfund Site  
 Portland, Oregon

3. Assumed amendment rates are summarized below:

Treatment Type	Diatomaceous Earth Amendment Rate
Stabilization/Solidification	5%
Thermal Desorption	10%
No Treatment - Subtitle C Disposal	10%
No Treatment - Subtitle D Disposal	5%

Note:

Quicklime amendment rate is based on the average amendment rate of two case studies presented in *Ex-Situ Treatment of Dense Non-Aqueous Phase Liquids Using Calcium Oxide (Quick Lime)*, Indiana Department of Environmental Management (IDEM), 2009. Amendment rates were 5% by weight and 5% by volume (8.84% by weight).

4. Assumed material densities are summarized below:

Diatomaceous Earth Density (LB/CF): 19  
 Diatomaceous Earth Density (TON/CY): 0.26  
*Source: MSDS (Wet Bulk Density)*

Quicklime Density (g/cm<sup>3</sup>): 3.25  
 Quicklime Density (TON/CY): 2.74  
*Source: Vendor Website - Quicklime Safety Data Sheet*

Dredged Sediment Density (LB/CY): 3,100  
 Dredged Sediment Density (TON/CY): 1.55  
*Source: Caterpillar Performance Handbook, edition 3.1 (Assumes Sand - Wet)*

#### Summary of Subtitle C Volumes by Area

	Alt. F Mod
Nav Subtitle C Dredge Volume (Low Overdredge) (CY)	30,200
Nav Subtitle C Dredge Volume (High Overdredge) (CY)	40,300
FMD Subtitle C Dredge Volume (Low Overdredge) (CY)	11,600
FMD Subtitle C Dredge Volume (High Overdredge) (CY)	15,500
Intermediate Subtitle C Dredge Volume (Low Overdredge) (CY)	85,800
Intermediate Subtitle C Dredge Volume (High Overdredge) (CY)	114,400
Shallow Subtitle C Dredge Volume (Low Overdredge) (CY)	41,100
Shallow Subtitle C Dredge Volume (High Overdredge) (CY)	54,800

#### Summary of Ex Situ Treatment Volumes

Total In-Water Ex-Situ Treatment Dredge Volume (Low Overdredge) (CY)	156,000
Total In-Water Ex-Situ Treatment Dredge Volume (High Overdredge) (CY)	208,000
Total In-Water Ex-Situ Treatment Dredge Volume (Average) (CY)	182,000
Total Riverbank Ex-Situ Treatment Excavation Volume (CY)	9,500
Total Combined Dredge/Excavation Volume (Low) (CY)	165,500
Total Combined Dredge/Excavation Volume (High) (CY)	217,500
Total Combined Dredge/Excavation Volume (Average) (CY)	191,500

Notes:

- Cells highlighted in Yellow are direct output quantities from R code. Green bold quantities are presented in ROD Text and Tables.
- Total in-water quantities are rounded to the nearest thousand. All other quantities are rounded to nearest hundred.

1 - Quantities with red bold formatting are cost estimate input values.  
 2 - Total quantities are rounded up to the nearest whole number.

**Quantities for Highly Toxic PTW**

	<b>Alt. F Mod</b>
Total Highly Toxic PTW Volume Dredged Neat	514,913
Low Highly Toxic PTW Volume with Overdredge	772,370
High Highly Toxic PTW Volume with Overdredge	1,029,826
<b>Highly Toxic PTW Dredged for Subtitle D Disposal (Not Including Riverbanks) (CY)</b>	<b>901,098</b>

Notes:

1 - Neat volumes are multiplied by an overdredge factor of 1.5 to estimate the "Low Volume with Overdredge" and multiplied by an overdredge factor of 2.0 to estimate the "High Volume with Overdredge"  
 2 - Dredge Volume Totals represent an average of the estimated Low and High Overdredge Volumes.  
 3 - Quantities above are rounded to the nearest whole number.

	Alt. F Mod
Significantly Augmented Reactive Cap (3ft)	NA
Dredge with significantly augmented reactive cap (3ft)	383.0
Dredge with significantly augmented reactive cap with Beachmix (3ft)	293.8
<b>Volume of Low Permeability Sand, Open Water Placement (CY):</b>	<b>677</b>

**Notes:**

1 - Cells highlighted in Yellow are direct output quantities from R code. Red bold quantities are cost estimate input values.

### Summary of Sand Quantities

	Alt. F Mod
<b>In-water Sand Material Quantities (including reactive layer mixing sand) (CY)</b>	<b>910,284</b>
<b>In-water Low Permeability Sand Material Quantities (CY)</b>	<b>3,946</b>
<b>Riverbanks Sand Material Quantities (CY)</b>	<b>97,629</b>
<b>Riverbanks Low Permeability Sand Material Quantities (CY)</b>	<b>4,465</b>
<b>Total Sand Material Quantities (does not include Low Permeability Sand) (CY)</b>	<b>1,007,913</b>
<b>Total Low Permeability Sand Material Quantities (CY)</b>	<b>8,411</b>

**Notes:**

1 - Total quantities are rounded up to nearest whole number.

### Cost Estimate Quantity Assumptions

- For purposes of estimating costs, total sand quantities presented below are assumed to include low permeability sand.
- Sand quantities (materials, placement and mixing) for reactive layers is presented in D2.g, and not included in the totals presented below.

	Alt. F Mod
<b>Total Sand Material Quantities, Including Low Permeability Sand (CY)</b>	<b>914,382</b>
<b>Confined Placement of Sand, Including Low Permeability Sand (CY)</b>	<b>81,653</b>
<b>Open Water Placement of Sand, Including Low Permeability Sand (CY)</b>	<b>730,635</b>
<b>Sand for Backfill and Capping Riverbanks, Including Low Permeability Sand (CY)</b>	<b>102,094</b>

**Notes:**

- Total quantities are rounded up to nearest whole number.
- Quantities with red bold formatting are cost estimate input values.

	Alt. F Mod
<b>In-water Sand Material Quantities (including reactive layer mixing sand) (CY)</b>	<b>910,000</b>
<b>In-water Low Permeability Sand Material Quantities (CY)</b>	<b>3,900</b>
<b>Riverbanks Sand Material Quantities (CY)</b>	<b>98,000</b>
<b>Riverbanks Low Permeability Sand Material Quantities (CY)</b>	<b>4,500</b>
<b>Total Sand Material Quantities (does not include Low Permeability Sand) (CY)</b>	<b>1,008,000</b>
<b>Total Low Permeability Sand Material Quantities (CY)</b>	<b>8,400</b>

**Notes:**

- Green bold quantities are presented in ROD Text and Tables.
- Low permeability sand quantities are rounded to nearest hundred. Sand quantities are rounded to the nearest thousand.

- 1 - Quantities with red bold formatting are cost estimate input values.
- 2 - Quantities for Armoring, Riverbank Areas with Armoring, and Total Mitigation Area are rounded up to the nearest whole number.
- 3 - Calculations for riverbank areas by technology assignment are presented in worksheet D2.b.

**Table D2.o. Truck, Rail, Barge Size Assumptions**

Portland Harbor Superfund Site  
Portland, Oregon

**Truck, Rail, Barge Size Assumptions**

The following densities, unit weights, and volume capacities were used for determination of the number of barge, truck, or rail gondola loads that may be required for transportation of contaminated material to an off-site disposal location and for transportation of import materials to the site. The densities for waste amended with diatomaceous earth or diatomaceous earth and quicklime were determined from weight and volume calculations presented in D2.d. Assumed average weight and volume per transportation method was based on previous work by others, quantity assumptions, or manufacturer literature. Densities utilized in the section are consistent with densities used in other sections of D2.d.

**Transportation Method Assumptions**

**Super Jumbo Barge**

	Length	Dimensions		Capacity	
		Width	Depth	Weight	Volume
		FT		TON	CY
Low End	250	40	9	2500	3333
High End	290	52	9	3000	5027

Source: River Mechanics (2002) - Pierre Julien

Density (TON/CY) > 0.76 means capacity is limited by weight for low end  
 Density (TON/CY) < 0.76 means capacity is limited by volume for low end

**Rail Gondola**

	Weight	Capacity	
		Volume	
	TON	CF	CY
65' Gondola	100-110	3242	120

Source: Standard Railroad Equipment Sizes - CSX Website

Density (TON/CY) > 0.83 means capacity is limited by weight for 65' gondola  
 Density (TON/CY) < 0.83 means capacity is limited by volume

**Density Calculations**

PORTLAND HARBOR RI/FS  
**APPENDIX G - UPDATE**  
**Detailed Analysis Cost Estimate**

# Memorandum

To: U.S. Environmental Protection Agency (EPA) Administrative Record

From: EPA Team

Date: November 16, 2016

Subject: Methodology and Organization of Selected Remedy Cost Estimate, Record of Decision, Portland Harbor Superfund Site

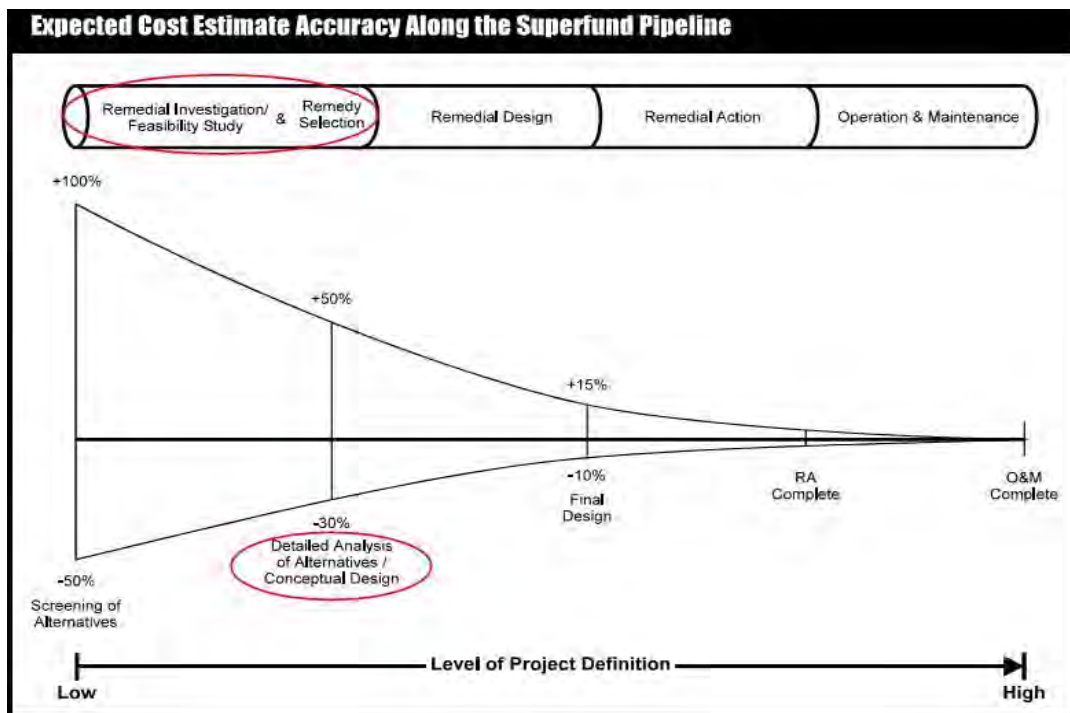

## Introduction

The EPA Record of Decision (ROD) Team has been tasked to develop a ROD cost estimate for Alternative F Modified (selected remedy) as part of the ROD for the Portland Harbor Superfund Site (herein referred to as "ROD cost estimate"). The ROD cost estimate is based on the scope of the selected remedy as presented in the ROD.

## Purpose and Accuracy of ROD Selected Remedy Cost Estimate

The ROD cost estimate was developed to support remedy selection, not to establish project budgets or negotiate Superfund settlements. At the ROD stage of the project, the "design" for the remedial action as represented by the selected remedy is still conceptual, not detailed, and the cost estimate is considered to be "order-of-magnitude".

Exhibit 1. Expected Cost Estimate Accuracy Along the Superfund Pipeline (EPA 2000)

The information provided in the cost estimate is based on the best available information regarding the anticipated scope of the selected remedy. As described in *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* (EPA 2000), this level of cost estimate is expected to have an accuracy between -30% to +50% of actual cost, based on the scope presented in the ROD. **Exhibit 1** illustrates the relationship between level of alternative scope definition and related accuracy as a typical project progresses through the CERCLA process.

## Generalized Scope of Selected Remedy

The selected remedy presented in the ROD includes the following primary scope elements to address contaminated sediment and riverbank soils as presented in the ROD text:

- Technology assignments
  - capping (several types depending on location and conditions)
  - dredging/excavation and related transportation/disposal
  - enhanced natural recovery (ENR)
- Monitored natural recovery (MNR)
- Institutional controls
- Monitoring and maintenance of remedy components (technology assignments as well as ICs) and five year site reviews

Other secondary elements of this scope include but are not limited to erosion/sedimentation best management practices and mitigation.

Transportation and disposal of dredged/excavated materials is a significant consideration that affects the overall costs of the selected remedy. As discussed in the text of the ROD, EPA selected offsite disposal for the selected remedy (i.e. confined disposal facility (CDF) disposal as indicated in the Proposed Plan was not selected).

The primary variable scope item between alternatives for off-site disposal is the type of facility used for off-site disposal of dredged/excavated contaminated sediments and riverbank soils and whether ex situ treatment is required prior to disposal. There are a number of complicating factors that can affect this decision such as presence of listed or characteristic RCRA hazardous waste, state hazardous waste (such as DDx), and designation of ex situ treatment principal threat waste (PTW) (i.e. not reliably contained [NRC]/non-aqueous phase liquid [NAPL] PTW). Assumptions for material management and disposal of dredged/excavated materials are consistent with the ROD text. In addition, the off-site facilities have the right to accept or reject the wastes proposed for disposal based on acceptance criteria.

The following assumptions were made for purposes of the ROD cost estimate with respect to management, disposal, and ex situ treatment (if needed) at off-site facilities:

- Contaminated materials designated for the Subtitle C/TSCA facility need to be sufficiently managed through pre-treatment (dewatering and/or amendment with diatomaceous earth) to pass the paint filter test.

- Contaminated materials designated for the Subtitle D facility need to be sufficiently managed through pre-treatment (dewatering assumed with diatomaceous earth) to minimize free liquids.
- All NRC/NAPL PTW will be disposed of at the representative Subtitle C/TSCA facility. Treatment assumptions prior to disposal at Subtitle C/TSCA facility were broken down by which of the two areas the NRC/NAPL PTW originated from (Area 6W or Area 7W).
- All NRC/NAPL PTW originating from Area 6W is assumed to undergo ex-situ solidification treatment (using quicklime) prior to disposal at the Subtitle C/TSCA facility.
- For NRC/NAPL PTW originating from Area 7W, one-third will undergo ex-situ solidification treatment (using quicklime) prior to disposal, one-third is assumed to undergo ex-situ low temperature thermal desorption treatment prior to disposal, and the remaining one-third is assumed to not require treatment prior to disposal at the Subtitle C/TSCA facility.
- Ex-situ stabilization/solidification will consist of quicklime amendment on the barge prior to transportation offsite for disposal.
- Ex-situ low temperature thermal desorption will be performed offsite at the Subtitle C/TSCA facility prior to disposal.
- All other contaminated sediment and riverbank soils designated for off-site disposal is assumed to be disposed of at the representative Subtitle D facility.
- No treatment will be performed for contaminated sediment and riverbank soils designated for the Subtitle D facility as they are assumed to have waste classifications and contaminant concentrations when generated that are acceptable to the facility.

Several modes of transport (truck, rail, and barge) are available for disposal of contaminated sediments and riverbank soils. After discussions with the representative Subtitle C/TSCA disposal facility (Chemical Waste Management of the Northwest) and the representative Subtitle D facility (Roosevelt Regional), the following assumptions were made for purposes of the ROD cost estimate with respect to transport methods for disposal at off-site facilities:

- Transport of contaminated sediment/riverbank soils to the Subtitle C/TSCA facility is assumed to be by barge. The representative facility's opinion is that barge transportation will have a cost similar to rail or trucking. For costing purposes, transloading was assumed to occur at the Port of Morrow, near Boardman, Oregon, followed by truck transportation from the Port of Morrow to the Subtitle C/TSCA facility.
- Transport of contaminated sediment/riverbank soils for off-site disposal at the Subtitle D facility is assumed to be by barge. The representative facility's opinion is that for their facility barge transport will have a cost representative of other transportation methods, and they provided unit costs for transloading at an off-site facility and truck transportation from the transload facility to the Subtitle D facility.

The selected remedy includes the work activities listed as follows.

***Major Work Activities Costed for Selected Remedy:***

1. Implementation of institutional controls

2. Mobilization/demobilization
3. Debris removal and disposal from dredge/excavation areas
4. Obstruction (i.e. structure and utility) removal and relocation from dredge/excavation areas
5. Dredging of contaminated sediments (both open water and confined dredging)
6. Excavation of riverbank materials (assumed for cost estimating purposes to be from barges)
7. Development of an offsite transload facility for facilitating off-site disposal of contaminated sediments and riverbank soils
8. Offloading of sediments to the transload facility
9. Management of dredged/excavated sediments and riverbank soils prior to off-site transportation to the transload facility, including ex-situ solidification for select NRC/NAPL PTW materials and dewatering for all materials.
10. Transportation (assumed to be by barge) to the off-site transload facility.
11. Transportation and disposal of contaminated sediments/riverbank soils at off-site facilities, including ex-situ thermal desorption treatment of select NRC/NAPL PTW materials at the off-site Subtitle C/TSCA facility
12. Placement of sand, beach mix, armor, reactive layer amendments, organoclay mats, and geofabric for technology assignments including capping, reactive residual layers, ENR, and in situ treatment (such as broadcast GAC)
13. Mitigation of nearshore areas impacted by activities such as capping, dredging, in situ treatment and ENR that extend to a depth of -13 feet NAVD88
14. MNR
15. Site-wide monitoring, cap area monitoring, and reactive layer monitoring
16. Long-term maintenance for capping, ENR, and in-situ treatment
17. Five-year site reviews

### ***Assumptions for Scope of Selected Remedy that Represent Cost Refinement Opportunities***

As described in the section above, for various elements of the selected remedy, assumptions were made about the scope and implementation of the selected remedy during remedial action. These assumptions are based on the best available information regarding the anticipated scope of the selected remedy and represent elements of scope that have significant impact on the overall estimated cost of the selected remedy. There could be opportunities for refinements to approaches during remedial design represented by these assumptions that could result in cost reductions, assuming other estimated costs during implementation do not increase. These include:

- Treatment of dredged/excavated materials - There are a number of complicating factors that can affect treatment of dredged/excavated contaminated sediments and riverbank soils, such as presence of listed or characteristic RCRA hazardous waste, state hazardous waste (such as DDX), and designation of ex situ treatment PTW (i.e. NRC/NAPL PTW). Based on future determinations of what types of treatment would be required, refinements to the treatment and

pre-treatment (dewatering and/or amendment with diatomaceous earth) approaches during the Remedial Design phase could potentially result in beneficial impacts to the costs.

- Disposal of dredged/excavated materials – In developing costs for disposal of contaminated sediments and riverbank soils, a preliminary evaluation of available landfill facilities was conducted. Based on that evaluation, assumptions were built into this cost estimate for representative Subtitle D and Subtitle C/TSCA landfill facilities, distances to those landfills, and tipping fees. Additional evaluation of available landfill facilities during the Remedial Design phase could result in further refinements to approach and thus cost.
- Transportation of dredged/excavated materials – For cost estimating purposes, barging was the assumed mode of transportation for offsite disposal of dredged/excavated materials. Further evaluation of other modes of transportation, such as rail, during the Remedial Design may result in beneficial impacts to costs. Additionally, as described above, further evaluation of landfill facilities could result in refinements to transportation distance to landfills that could beneficially affect costs.
- Dredging – In developing the costs for dredging, quantities for dredging were split out into open water and confined dredging. Crews and unit costs for open water dredging and confined dredging were developed with open water dredging assuming larger equipment and crews, but also higher productivity. During the Remedial Design phase, further refinement is expected in delineating open water and confined dredge areas as well as potentially refining the type of equipment that would be required for each type of dredging that could potentially result in reduced costs for dredging.
- Mitigation – Assumptions were made concerning types of capping and residual layer materials that would constitute onsite mitigation and would reduce the requirements for offsite mitigation. Coordination with Oregon Department of Fish and Wildlife (ODFW), National Marine Fisheries Service (NMFS), and U.S. Fish and Wildlife Service (USF&W) would need to be conducted during future phases in order to determine mitigation requirements under CWA 404 and ESA. In addition, mitigation costs were based on numerous projects in the Pacific Northwest region rather than local, Portland-specific mitigation. Therefore, current mitigation assumptions may need to be re-evaluated in future phases which could potentially result in cost reductions.
- Reactive Layers - For cost estimating purposes, assumptions were made about depths of reactive materials for reactive layers and the type of reactive materials that would be used for these reactive layers. During the Remedial Design phase, the definition of these assumptions will be further refined and could result in beneficial impacts to costs.
- Erosion/Residual Control Measures and Obstruction Removal/Relocation – Costs for erosion/residual control measures, including silt curtains and sheet piles, and obstruction removal/relocation were estimated using technology assignment figures for the selected remedy. During the Remedial Design phase further refinement is expected for these components, including what specific types of erosion/residual control measures would be required and where they would be required as well as what obstructions would require removal or relocation. Depending on the revised assumptions, these could potentially result in reduced costs.

As previously stated, the cost estimate developed in the ROD for the selected remedy is not meant to establish project budgets or negotiate Superfund settlements because they are conceptual, not detailed, and the cost estimate is considered “order-of-magnitude” with an expected accuracy that could result in costs as much as 50 percent greater during implementation than currently projected. This is particularly true of the Portland Harbor Superfund Site that involves remediation of miles of river with potentially hundreds of property owners that could involve incremental implementation and funding. Thus, any potential cost reductions indicated here may be nullified by increases in costs for other estimated activities within the scope of the selected remedy.

## **General Methodology and Relevant Cost Guidance**

This cost estimate was developed according to *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 2000). Flexibility is incorporated into the selected remedy for the location of remedial facilities, the selection of cleanup levels, and the period in which remedial action will be completed.

Types of costs that are assessed for the selected remedy include the following:

- Capital costs
- Periodic costs
- Present value of capital and periodic costs

The levels of detail employed in making this estimate are conceptual but are considered appropriate for the remedy selection process. The information provided in the cost estimate is based on the best available information regarding the anticipated scope of the selected remedy.

The costs are evaluated with respect to the following categories:

- Capital costs are expenditures that are required to construct a remedial action. They are exclusive of costs required to operate or maintain the action throughout its lifetime. Capital costs consist primarily of expenditures initially incurred to build or install the remedial action. Capital costs include all labor, equipment, and material costs (including contractor markups, such as overhead and profit) associated with activities, such as mobilization/demobilization, site work, dredging of sediments, installation of caps, and disposal facilities. Capital costs also include expenditures for professional/technical services that are necessary to support construction of the remedial action. The construction activities occurring as capital costs include major work activities 1 through 13.
- Periodic costs are costs that occur only once every few years (e.g., 5-year reviews, monitoring, and maintenance) or expenditures that occur only once during the entire O&M period or remedial time frame (e.g., site closeout and remedy failure/replacement). These costs may be either capital or O&M costs, but because of their periodic nature, it is more practical to consider them separately from other capital or O&M costs in the estimating process. The post-construction activity occurring on a periodic basis that is typical of capital costs is the pre-construction baseline MNR event for major work activity 13. The post-construction activities

occurring on a periodic basis that are typical of O&M costs include major work activities 14 through 17.

- The present value cost represents the amount of money that, if invested in the initial year of the remedial action at a given rate, would provide the funds required to make future payments to cover all costs associated with the remedial action over its planned life. Future O&M and periodic costs are included and reduced by the appropriate present value real discount rate (7%) as outlined in *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 540-R-00-002, July 2000). Inflation and depreciation were not considered in preparing the present value costs developed from the constant dollar analysis that the undiscounted capital and periodic costs represent.

## Development Approach for Information Provided in Cost Worksheets

Unit quantities (lengths, areas and volumes) used to cost activities such as capping, dredging, in-situ treatment, ENR, MNR, transport, and disposal were developed for each alternative primarily using the results of the technology assignment modeling performed using the software called "R". Additional calculations were developed to supplement the quantities provided by the model. Output quantities from the technology assignment model and supplemental calculations are provided in Appendix IV. In addition to the model quantities and supplemental calculations, additional quantities such as obstruction removal and relocation, riverbanks, mitigation, and installation of silt curtains and sheet piles were estimated from the technology assignment figures for the selected remedy. Information provided by Anchor QEA, vendors, literature from sites of similar scope, as well as engineering judgment was used to develop quantity assumptions and other design components not estimated from the technology assignment model or figures.

Unit costs were derived from three main sources:

- EPA-Derived Unit Costs – EPA-derived unit costs were prepared using USACE's Micro Computer Aided Cost Engineering System (MCACES) Second Generation (MII) software version 4.2, Build 3. This is the software platform generally used by Federal agencies, including the EPA, to develop construction cost estimates for CERCLA remedial actions. The MII unit costs account for local market conditions to the degree practicable (e.g. the estimate uses local Davis Bacon wage rate determinations for labor costs and local fuel and energy rates for equipment costs). Crews and productivities were developed based on assumptions within the ROD. Assumptions for the MII crews and productivities are presented in the MII backup calculations (PDSM-01, CRW-01, and PD-01).
- Unit Costs Previously Developed by Anchor QEA – These unit costs were derived from costs developed by Anchor QEA in 2010. Crew productivities assumed in development of the unit costs by Anchor QEA were not modified by EPA. These unit costs were originally obtained in 2010 and were escalated to the base year of these estimates (2016) using the Civil Works Construction Cost Index System (CWCCIS), Engineer Manual (EM) 1110-2-1304, Amendment #7 revised as of 30 September 2015. In addition, some of these unit costs were converted to another unit of measure using assumed densities as presented in the cost buildup calculations (CALC-1).

- Project-Specific Vendor Quotes – EPA obtained project-specific vendor quote for numerous items including, but not limited to, transportation and disposal of waste at off-site disposal facilities, reactive layer amendments, and quicklime.

In instances where these three cost sources were not sufficient for costing all major work activities, supplemental unit costs were obtained. Costs that were derived from other sources include the following:

- Vendor quotes from a project of similar scope were utilized for geotextile material and placement costs.
- Unit costs for professional labor rates included in the labor rate backup were determined using FLCdatacenter.com tailored to the Portland, Oregon area. These labor rates were used in developing costs for implementation of institutional controls, evaluating and updating institutional controls, and five-year site reviews.
- The mitigation unit cost was calculated from the average cost of projects presented in Tables 6.1-1 and 6.1-4 of the Appendix M, Attachment 1, Anchor QEA FS (2010) as well as select other projects. The calculation of the mitigation cost is presented in the summary of cost buildup (CALC-MITIGATION).
- Mobilization/demobilization costs are applied as a percentage of the capital cost for each alternative. This percentage was based on an evaluation of the mobilization/demobilization costs presented in the detailed cost estimates of the Lower Duwamish Waterway Final Feasibility Study (EPA 2012). Lower Duwamish mobilization/demobilization costs accounted for approximately 1.5%-1.6% of total capital costs for each alternative based on the scope of the work. The scope and duration of the remedial activities assumed for each of the Lower Duwamish Waterway FS alternatives was taken into consideration when determining the cost assumption for mobilization/demobilization presented in the ROD. The derivation of the mobilization/demobilization assumption is presented in the summary of cost buildup (CALC-01).

Specific modifications from the general approach and shown in the cost worksheets include the following:

- Unit costs developed by EPA using MII include contractor markups such as overhead and profit; therefore, additional no additional overhead and profit was added to these items in the cost worksheets.
- Unit cost buildups provided by Anchor QEA (including quotes) indicate they include prime contractor overhead and profit; thus, no additional overhead and profit was added to these items.
- Disposal and treatment costs obtained by EPA from the disposal facilities presumably include the facility's overhead and profit. However, the prime contractor implementing the work would likely need to have some type of overhead costs for administering and tracking disposal off-site. Thus a handling fee of 1 percent was included in the prime contractor overhead but no additional profit was added on that activity.

- In addition to disposal and treatment costs, EPA obtained vendor quotes for materials such as reactive layer amendments and quicklime. For these items, a handling fee of 5 percent was included in the prime contractor overhead but no additional profit was added.

## **Development Approach for Information Provided in Cost Summary Tables**

The cost summary tables are organized by the two major cost categories: capital costs and periodic costs. Costs are totaled for each major work activity. Contingency and professional/technical services are applied within the cost summary tables after subtotaling the costs for major work activities. Percentages used for contingency and professional/technical services costs are based on the recommended ranges presented in Section 5.0 of *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* (EPA 2000), unless otherwise noted within the cost summary tables.

Specific modifications from the general approach and shown in the cost summary tables include the following:

- As described in Section 5.4 of *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, engineering judgment may be used to adjust rule-of-thumb percentages presented in Exhibit 5-6 for scope contingency with a lower contingency indicating that project scope will undergo minimal change during design. Due to the high overall costs for major work activities and a detailed level of conceptual design performed as part of the technology assignment modeling, the scope contingency percentages were modified to the low end of the recommended range presented in the guidance, to better reflect the detailed evaluation and concepts developed for these items.
- As described in Section 5.5 of *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, engineering judgment may be used to adjust rule-of-thumb percentages presented in Exhibit 5-8 for project management, remedial design, and construction management as well as the recommended range presented for technical support. Due to the high overall costs for major work activities, the professional/technical percentages were modified to lower than the recommended range presented in the guidance, to better reflect realistic costs for professional/technical services costs for these items.
- As described in Section 5.6 of *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, contingency is generally not applied to institutional control cost elements. However, due to the complexity of the site and the numerous property owners involved at the site, a 15% contingency (10% Scope, 5% Bid) was applied to account for uncertainties relating to implementation of institutional controls and a 10% contingency (10% Scope, 0% Bid) was applied to account for uncertainties relating to evaluating and updating institutional controls.
- As described in Section 5.5 of *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study*, bid contingency is typically applied to remedial action construction or O&M activities. Since costs for 5-Year Site Reviews fall outside that definition, bid contingency was not applied for 5-Year Site Review Periodic Costs and only 10% scope contingency was applied.

## Development Approach for Information Provided in Present Value Tables

The present value cost represents the amount of money that, if invested in the initial year of the remedial action at a given rate, would provide the funds required to make future payments to cover all costs associated with the remedial action over its planned life. Future O&M periodic costs are included and reduced by the appropriate present value discount rate as outlined in *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 2000a). Per the guidance, the present value analysis was performed on the selected remedy using a 7 percent real discount (interest) rate over the period of evaluation for the selected remedy. Per guidance, inflation and depreciation were not considered in preparing the present value costs.

Specific modifications from the general approach and shown in the present value tables include the following:

- As discussed in *A Guide to Developing and Documenting Cost Estimates during the Feasibility Study* (EPA 2000), the real discount (interest) rate used for present value analysis depends on whether the Site is classified as a federal facility site. Federal facility sites are former or current installations operated or controlled by a federal government agency and identified by EPA's Federal Facilities Restoration and Reuse Office (FFRRO). Based on a cursory review, the areas within the Site are not a federal facility identified within FFRRO's site inventory. In addition, the guidance specifically mentions that although a federal-lead site cleaned up by EPA using the Superfund trust fund (i.e., fund-lead sites) may be an analogous situation to a federal facility site being cleaned up using Superfund authority, there is always a chance that a potentially responsible party (PRP) could remediate the Site. Thus, per guidance a real discount rate of 7 percent should be used in calculating present value costs for all non-federal facility sites. A 7 percent real discount rate was used to develop present value costs for the selected remedy over the period of evaluation since there is PRP involvement and the site or areas within the site are not identified as federal facilities in the FFRRO site inventory.
- The project duration for the selected remedy is longer than the period of evaluation for present value analysis (Years 0 through 30 as selected by EPA). The guidance indicates in those situations that site-specific justification for the selected period of evaluation should be provided. It is likely that the selected remedy would require an indefinite duration of O&M (evaluated as periodic costs within these estimates). However, evaluation of long durations of O&M is cumbersome and is generally not necessary for comparative evaluation between alternatives because of the effects of cost discounting in later years under present value analysis. The period of analysis for the ROD is assumed to be 30 years, because the increase of present value cost due to small periodic expenditures for maintenance and monitoring after 30 years is minimal relative to the accuracy range of the estimates.
- As described in Section 4.2 of *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* (EPA 2000), most cost analyses assume that initial construction and startup will occur in year zero, but this assumption can be modified if it is known that capital costs will be expended beyond one year. Capital costs for the selected remedy were split out evenly over assumed construction durations. Due to the vast size of the cleanup and factors external to the project, construction durations were assumed to be longer than the minimum calculated which were based solely on productivities and work windows. The assumed

construction duration for the selected remedy (starting at Year 0) is 13 years. This was based on the construction duration for Alternative F without modifications. While the construction duration may be slightly less for Alternative F Modified, the estimated duration would be conservative and would not affect undiscounted costs. The impact to present value cost would not be significant relative to the expected accuracy range of the estimate.

- In addition, a “no-discounting” scenario is included for the present value analysis of the selected remedy as recommended by the guidance for long-term projects (e.g., project duration exceeding 30 years). A non-discounted constant dollar cash flow over time demonstrates the impact of a discount rate on the total present value cost and the relative amounts of future annual expenditures. Non-discounted constant dollar costs are presented for comparison purposes only and should not be used in place of present value costs in the Superfund remedy selection process.

## **Record of Decision Selected Remedy Cost Estimate Organization**

The ROD selected remedy cost estimate are organized into the following sections:

- Methodology and Organization of the Selected Remedy Cost Estimate, Record of Decision, Portland Harbor Superfund Site

This is the memorandum you are currently reading that summarizes the approach to developing the selected remedy cost estimate within the ROD for the Portland Harbor Superfund Site.

- Alternative F Modified Cost Estimate

**Alternative F Modified Cost Estimate**

**The cost spreadsheets included in this appendix were developed in accordance with EPA 540-R-00-002 (OSWER 9355.0-75) July 2000.**

**Costs for project management, remedial design, and construction management were determined as percentages of capital cost per the guidance. Costs for these work items may not reflect costs for implementation. These costs are determined based on specific client requirements during implementation.**

**Cost Summary  
Alternative F Modified**

**TABLE CS-SUMMARY****SELECTED REMEDY COST SUMMARY**

**Site:** Portland Harbor Superfund Site  
**Location:** Portland, Oregon  
**Phase:** Record of Decision (-30% to +50%)  
**Base Year:** 2016

<u>Selected Alternative</u>	<u>Total Capital Cost</u>	<u>Total Periodic Cost</u>	<u>Total Non-Discounted Cost</u>	<u>Present Value Cost</u>
F Modified	\$1,184,607,000	\$524,028,000	\$1,708,635,000	\$1,054,200,000

**Notes:**

- 1 - Capital costs, annual costs, and periodic costs are presented on Table CS-F (MOD).
- 2 - Estimated remedial timeframe and associated present value analysis for the selected alternative are provided on Table PV-F (MOD).
- 3 - The total present value cost demonstrates the impact of a discount rate on the total non-discounted cost and the relative amount of future annual expenditures. Non-discounted costs are presented for comparison purposes only and should not be used in place of present value costs in the CERCLA remedy selection process.
- 4 - Costs presented for this alternative are expected to have an accuracy between -30% to +50% of actual costs, based on the scope presented.

<b>TOTALS:</b>	\$4,573,000	\$9,486,000	\$1,170,548,000	\$474,600,000	\$47,580,000	\$1,848,000	\$1,708,635,000		\$1,054,204,802
<b>TOTAL PRESENT VALUE OF ALTERNATIVE F MODIFIED<sup>5</sup></b>									<b>\$1,054,200,000</b>

**Notes:**

- <sup>1</sup> The selected remedy is expected to require cost expenditures for perpetuity since some contamination addressed by the remedy within the sediment bed and associated riverbank soils would remain in-place that do not allow for unrestricted use or unlimited exposure to human or ecological receptors. However, the period of analysis was assumed to be 30 yrs beyond the start of construction in Year 0.
- <sup>2</sup> Capital costs, for purposes of this analysis, are assumed to be distributed as indicated on Table CS-F(MOD).
- <sup>3</sup> Total annual expenditure is the total cost per year with no discounting.
- <sup>4</sup> Present value is the total cost per year including a 7.0% discount factor for that year. See Table PV-ADRFT for details.
- <sup>5</sup> Total present value is rounded to the nearest \$10,000. Inflation and depreciation are excluded from the present value cost. Costs presented for this alternative are expected to have an accuracy between -30% to +50% of actual costs, based on the scope presented.

		YR	Years

**Cost Database Code:**  
 The Cost Database Code is a reference code for linking with line item cost information with the cost source database and is not otherwise used within these cost worksheets. The following cost source database prefixes apply:  
 L (EPA-Derived Labor Unit Costs), M (Project-Specific Vendor Unit Costs), P (Previously Developed Unit Costs by Anchor QEA for Portland Harbor), A (EPA-Derived MII Unit Costs), O (Unit Costs from Other Projects/Sources)

**Source of Cost Data:**  
 For citation references, the following sources apply:  
 ALL (Allowance), FLC (www.flodatacenter.com), LD (Costs Derived from Lower Duwamish Waterway Final Feasibility Study), MII (MII), O (Other), P (Previously Developed by Anchor QEA for Portland Harbor), and V (Vendor Quote)

**Cost Adjustment Checklist:**

<b>FACTOR:</b>	<b>NOTES:</b>
H&S Productivity (labor and equipment only)	Field work will be in Level 'D' PPE.
Escalation to Base Year	MII assembly costs include HPF adjustments.
Area Cost Factor	2016 cost sources are not escalated (EF=1.00). All other costs are escalated based on the USACE CWCCIS, EM 1110-2-1304, Sept 2015.
Subcontractor Overhead and Profit	An AF of 1.05 is used for Oregon, except that an AF of 1.00 (national unmodified average) is used for MII assembly costs and local vendor quotes.
Prime Contractor Overhead and Profit	It is assumed that home office OH is 8% and profit is 9% for the Prime Contractor. Professional labor overhead is 100%. Allowances and items with mandated costs such as per diem do not have overhead and profit applied.
	Items previously developed by Anchor QEA already include contractor markups, therefore overhead and profit were not applied to those items.
	It is assumed that OH is 1% and profit is 0% for vendor quotes for treatment and disposal at offsite disposal facilities. It is assumed that OH is 5% and profit is 0% for quotes for all other material vendor quotes.
	Items developed using MII already include contractor markups such as overhead and profit, therefore additional overhead and profit were not applied in the PC OH and PC PF to those items.

H&S Productivity (labor and equipment only)	MII assembly costs include HPF adjustments.
Escalation to Base Year	2016 cost sources are not escalated (EF=1.00). All other costs are escalated based on the USACE CWCCIS, EM 1110-2-1304, Sept 2015.
Area Cost Factor	An AF of 1.05 is used for Oregon, except that an AF of 1.00 (national unmodified average) is used for MII assembly costs and local vendor quotes.
Subcontractor Overhead and Profit	It is assumed that home office OH is 8% and profit is 9% for the Prime Contractor. Professional labor overhead is 100%.
Prime Contractor Overhead and Profit	Allowances and items with mandated costs such as per diem do not have overhead and profit applied. Items previously developed by Anchor QEA already include contractor markups, therefore overhead and profit were not applied to those items. It is assumed that OH is 1% and profit is 0% for vendor quotes for treatment and disposal at offsite disposal facilities. It is assumed that OH is 5% and profit is 0% for quotes for all other material vendor quotes. Items developed using MII already include contractor markups such as overhead and profit, therefore additional overhead and profit were not applied in the PC OH and PC PF to those items.

**COST WORKSHEET**

**Periodic Cost Sub-Element  
Evaluating and Updating Institutional Controls**

Site: Portland Harbor Superfund Site  
 Location: Portland, Oregon  
 Phase: Record of Decision  
 Base Year: 2016

Prepared By: JN Date: 10/20/2016  
 Checked By: MS Date: 10/27/2016

**Work Statement:**  
 This sub-element involves evaluating and updating of institutional controls for the site. The following cost includes labor and materials to required for evaluating and updating institutional controls every 5 years.  
 Quantity development presented in Appendix IV.

**Cost Analysis:**  
 Cost for Evaluating and Updating Institutional Controls (Lump Sum)

PC PF	Prime Contractor Profit	LS	Lump Sum
BUR LIC	Burdened Line Item Cost	MO	Month
		SF	Square Foot
		SY	Square Yard
		TON	Tons
		YR	Years

**Cost Database Code:**

The Cost Database Code is a reference code for linking with line item cost information with the cost source database and is not otherwise used within these cost worksheets. The following cost source database prefixes apply:

L (EPA-Derived Labor Unit Costs), M (Project-Specific Vendor Unit Costs), P (Previously Developed Unit Costs by Anchor QEA for Portland Harbor), A (EPA-Derived MII Unit Costs), O (Unit Costs from Other Projects/Sources)

**Source of Cost Data:**

For citation references, the following sources apply:

ALL (Allowance), FLC (www.flcdatabcenter.com), LD (Costs Derived from Lower Duwamish Waterway Final Feasibility Study), MII (MII), O (Other), P (Previously Developed by Anchor QEA for Portland Harbor), and V (Vendor Quote)

**Cost Adjustment Checklist:**

**FACTOR:**  
 H&S Productivity (labor and equipment only)  
 Escalation to Base Year  
 Area Cost Factor  
 Subcontractor Overhead and Profit  
 Prime Contractor Overhead and Profit

**NOTES:**

Field work will be in Level "D" PPE.  
 MII assembly costs include HPF adjustments.  
 2016 cost sources are not escalated (EF=1.00). All other costs are escalated based on the USACE CWCCIS, EM 1110-2-1304, Sept 2015.  
 An AF of 1.05 is used for Oregon, except that an AF of 1.00 (national unmodified average) is used for MII assembly costs and local vendor quotes.  
 It is assumed that home office OH is 8% and profit is 9% for the Prime Contractor. Professional labor overhead is 100%.  
 Allowances and items with mandated costs such as per diem do not have overhead and profit applied.  
 Items previously developed by Anchor QEA already include contractor markups, therefore overhead and profit were not applied to those items.  
 It is assumed that OH is 1% and profit is 0% for vendor quotes for treatment and disposal at offsite disposal facilities. It is assumed that OH is 5% and profit is 0% for quotes for all other material vendor quotes.  
 Items developed using MII already include contractor markups such as overhead and profit, therefore additional overhead and profit were not applied in the PC OH and PC PF to those items.

 2016 cost sources are not escalated (EF=1.00). All other costs are escalated based on the USACE CWCCIS, EM 1110-2-1304, Sept 2015.  
 An AF of 1.05 is used for Oregon, except that an AF of 1.00 (national unmodified average) is used for MII assembly costs and local vendor quotes.  
 It is assumed that home office OH is 8% and profit is 9% for the Prime Contractor. Professional labor overhead is 100%.  
 Allowances and items with mandated costs such as per diem do not have overhead and profit applied.  
 Items previously developed by Anchor QEA already include contractor markups, therefore overhead and profit were not applied to those items.  
 It is assumed that OH is 1% and profit is 0% for vendor quotes for treatment and disposal at offsite disposal facilities. It is assumed that OH is 5% and profit is 0% for quotes for all other material vendor quotes.  
 Items developed using MII already include contractor markups such as overhead and profit, therefore additional overhead and profit were not applied in the PC OH and PC PF to those items.

	174,300	SF	\$1,113,777	\$6.39

**Notes:**

Further information about the development of cost worksheets can be found in the memorandum - Methodology and Organization of Selected Remedy Cost Estimate. The quantity bolded in the QTY column is the quantity selected as the representative unit quantity for this cost worksheet. If multiple quantities are bolded, the representative unit quantity is the sum of those quantities. When the LS unit is utilized, the default representative unit quantity is 1.  
 HTRW productivity factor is from Exhibit B-3 or B-4 of "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study", EPA 2000  
 EPA developed project-specific unit costs using the Micro Computer Aided Cost Engineering System (MCACES) Second Generation (MII) software version 4.2, build 3

**Abbreviations:**

QTY	Quantity	AC	Acre
EQUIP	Equipment	CLF	100 Linear Foot
MATL	Material	CY	Cubic Yard
HPF	HTRW Productivity Factor	DY	Days
ADJ LABOR	Adjusted Labor for HFP	EA	Each
ADJ EQUIP	Adjusted Equipment for HFP	FTE	Full Time Equivalent
UNMOD UC	Unmodified Unit Cost	HR	Hours
UNMOD LIC	Unmodified Line Item Cost	LB	Pounds

		SF	Square Foot
		SY	Square Yard
		TON	Tons
		YR	Years

**Cost Database Code:**

The Cost Database Code is a reference code for linking with line item cost information with the cost source database and is not otherwise used within these cost worksheets. The following cost source database prefixes apply:  
 L (EPA-Derived Labor Unit Costs), M (Project-Specific Vendor Unit Costs), P (Previously Developed Unit Costs by Anchor QEA for Portland Harbor), A (EPA-Derived MII Unit Costs), O (Unit Costs from Other Projects/Sources)

**Source of Cost Data:**

For citation references, the following sources apply:  
 ALL (Allowance), FLC (www.flcdatabase.com), LD (Costs Derived from Lower Duwamish Waterway Final Feasibility Study), MII (MII), O (Other), P (Previously Developed by Anchor QEA for Portland Harbor), and V (Vendor Quote)

**Cost Adjustment Checklist:**

**NOTES:**

**FACTOR:**  
 H&S Productivity (labor and equipment only)  
 Escalation to Base Year  
 Area Cost Factor  
 Subcontractor Overhead and Profit  
 Prime Contractor Overhead and Profit

Field work will be in Level "D" PPE.  
 MII assembly costs include HPF adjustments.  
 2016 cost sources are not escalated (EF=1.00). All other costs are escalated based on the USACE CWCCIS, EM 1110-2-1304, Sept 2015.  
 An AF of 1.05 is used for Oregon, except that an AF of 1.00 (national unmodified average) is used for MII assembly costs and local vendor quotes.  
 It is assumed that home office OH is 8% and profit is 9% for the Prime Contractor. Professional labor overhead is 100%.  
 Allowances and items with mandated costs such as per diem do not have overhead and profit applied.  
 Items previously developed by Anchor QEA already include contractor markups, therefore overhead and profit were not applied to those items.  
 It is assumed that OH is 1% and profit is 0% for vendor quotes for treatment and disposal at offsite disposal facilities. It is assumed that OH is 5% and profit is 0% for quotes for all other material vendor quotes.  
 Items developed using MII already include contractor markups such as overhead and profit, therefore additional overhead and profit were not applied in the PC OH and PC PF to those items.

<b>Location:</b> Portland, Oregon	<b>Checked By:</b> MS	<b>Date:</b> 10/27/2016
<b>Phase:</b> Record of Decision		
<b>Base Year:</b> 2016		

**Work Statement:**  
 This sub-element involves the development of a transload facility for facilitating offsite disposal of contaminated sediments. It includes costs for on-site labor, equipment, and materials developed from previous work. Transload facility is expected to be operated for 19 years, based on estimated construction duration. Property lease quantity (20 acres) adjusted for construction duration. Labor for the annual inspections is assumed to be 2.5 times full time equivalent. Environmental monitoring is assumed to be once per quarter year for construction duration.

**Cost Analysis:**  
 Cost for Transload Facility Development (Lump Sum)

COST WORKSHEET

Periodic Cost Sub-Element  
 Long-Term Maintenance for Capping, ENR, and In Situ Treatment

Site: Portland Harbor Superfund Site  
 Location: Portland, Oregon  
 Phase: Record of Decision  
 Base Year: 2016

Prepared By: JN Date: 10/20/2016  
 Checked By: MS Date: 10/27/2016

**Work Statement:**  
 This sub-element involves replacement of 5% of the technology assignment layers as part of long-term maintenance. It includes costs for on-site labor, equipment, and materials developed from previous work. Quantities represent 5% of material placement quantities which were developed and presented in Appendix IV.

**Cost Analysis:**  
 Cost for Long-Term Maintenance (Lump Sum)

<b>COST WORKSHEET SUMMARY</b>	1	LS	\$5,153,976	\$5,153,976

**Notes:**  
 Further information about the development of cost worksheets can be found in the memorandum - Methodology and Organization of Selected Remedy Cost Estimate. The quantity bolded in the QTY column is the quantity selected as the representative unit quantity for this cost worksheet. If multiple quantities are bolded, the representative unit quantity is the sum of those quantities. When the LS unit is utilized, the default representative unit quantity is 1.  
 HTRW productivity factor is from Exhibit B-3 or B-4 of "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study", EPA 2000  
 EPA developed project-specific unit costs using the Micro Computer Aided Cost Engineering System (MCACES) Second Generation (MII) software version 4.2, build 3

**Cost Database Code:**  
 The Cost Database Code is a reference code for linking with line item cost information with the cost source database and is not otherwise used within these cost worksheets. The following cost source database prefixes apply:  
 L (EPA-Derived Labor Unit Costs), M (Project-Specific Vendor Unit Costs), P (Previously Developed Unit Costs by Anchor QEA for Portland Harbor), A (EPA-Derived MII Unit Costs), O (Unit Costs from Other Projects/Sources)

**Source of Cost Data:**  
 For citation references, the following sources apply:  
 ALL (Allowance), FLC (www.flcdatabase.com), LD (Costs Derived from Lower Duwamish Waterway Final Feasibility Study), MII (MII), O (Other), P (Previously Developed by Anchor QEA for Portland Harbor), and V (Vendor Quote)

**Abbreviations:**

		YR	Years

<b>Cost Adjustment Checklist:</b>	<b>NOTES:</b>
FACTOR:	Field work will be in Level "D" PPE.
H&S Productivity (labor and equipment only)	MII assembly costs include HPF adjustments.
Escalation to Base Year	2016 cost sources are not escalated (EF=1.00). All other costs are escalated based on the USACE CWCCIS, EM 1110-2-1304, Sept 2015.
Area Cost Factor	An AF of 1.05 is used for Oregon, except that an AF of 1.00 (national unmodified average) is used for MII assembly costs and local vendor quotes.
Subcontractor Overhead and Profit	It is assumed that home office OH is 8% and profit is 9% for the Prime Contractor. Professional labor overhead is 100%.
Prime Contractor Overhead and Profit	Allowances and items with mandated costs such as per diem do not have overhead and profit applied.
	Items previously developed by Anchor QEA already include contractor markups, therefore overhead and profit were not applied to those items.
	It is assumed that OH is 1% and profit is 0% for vendor quotes for treatment and disposal at offsite disposal facilities. It is assumed that OH is 5% and profit is 0% for quotes for all other material vendor quotes.
	Items developed using MII already include contractor markups such as overhead and profit, therefore additional overhead and profit were not applied in the PC OH and PC PF to those items.

PROJECT: Portland Harbor FS  
 JOB NO.: 79171.3383.345.FSZ  
 CLIENT: EPA

COMPUTED BY: JN  
 DATE: 3/4/2016

CHECKED BY: AB  
 DATE CHECKED: 3/7/2016  
 WRKSHT NO.: CALC-1

Description: Summary of cost buildup for unit costs for detailed costing of alternatives for Portland Harbor FS.

Estimate Base Year	2016	
<b>Assumed Material Properties</b>		
Density of Sand (wet), LB/LCY:	3,100	Caterpillar Performance Handbook, edition 3.1
Density of Sand (dry), LB/LCY:	2,400	Caterpillar Performance Handbook, edition 3.1
Density of Riprap, LB/LCY:	2,700	Caterpillar Performance Handbook, edition 3.1
Density of Gravel (pitrun), LB/LCY:	3,250	Caterpillar Performance Handbook, edition 3.1
<b>Material and Placement Costs for Capping Materials</b>		
<b>Material Costs</b>		
Sand Material Cost, \$/TN:	\$14.60	cost developed by Anchor QEA, 2010 (See Backup Table 29A) based on material cost from Knife River quote #7838 (2010)
Sand Material Cost, \$/LB:	\$0.0073	
<b>Unescalated Sand Material Cost, \$/LCY:</b>	<b>\$17.52</b>	
<b>Unescalated Backfill Material Cost, \$/LCY:</b>	<b>\$17.52</b>	Assumes backfill will be sand
ODOT 200 Armor Material Cost, \$/TN:	\$31.50	cost developed by Anchor QEA, 2010 (See Backup Table 29A) based on material cost from Knife River quote #7838 (2010)
ODOT 200 Armor Material Cost, \$/LB:	\$0.0158	
<b>Unescalated ODOT 200 Armor Material Cost, \$/LCY:</b>	<b>\$51.19</b>	Assumed density of Gravel (pitrun)
Beach Mix Material Cost, \$/TN:	\$31.50	cost developed by Anchor QEA, 2010 (See Backup Table 29A) based on material cost from Knife River quote #7838 (2010)
Beach Mix Material Cost, \$/LB:	\$0.0158	
<b>Unescalated Beach Mix Material Cost, \$/LCY:</b>	<b>\$51.19</b>	Assumed density of Gravel (pitrun)
Diatomaceous Earth Material Cost, \$/TN:	\$94.00	material cost from Waste Management (2010), see Anchor QEA, 2010 (See Backup Table 24)
<b>Unescalated Diatomaceous Earth Material Cost, \$/TN:</b>	<b>\$94.00</b>	
Geotextile Material Cost, \$/SY:	\$1.16	material cost from vendor quote (2014) for 8 oz/sy geotextile
<b>Unescalated Geotextile Material Cost, \$/AC:</b>	<b>\$5,614.40</b>	
Organoclay Material Cost, \$/SF:	\$2.70	cost developed by Anchor QEA, 2010 (See Backup Table 29A) based on material cost from Cetco quote (2010), excludes 15% cost increase for overlap
<b>Unescalated Organoclay Material Cost, \$/SF:</b>	<b>\$2.70</b>	
Geotextile Installation Cost, \$/SF:	\$0.16	installation cost from vendor quote (2014) for 8 oz/sy geotextile
<b>Unescalated Geotextile Installation Cost, \$/AC:</b>	<b>\$6,969.60</b>	
<b>Unit Costs for Obstruction and Debris Removal</b>		
Pile Removal and Disposal, \$/EA:	\$635	cost developed by Anchor QEA, 2010 (See Backup Table 3), includes removal and disposal
<b>Unescalated Pile Removal and Disposal, \$/EA:</b>	<b>\$635.00</b>	
Pile Replacement, \$/EA:	\$6,636	cost developed by Anchor QEA, 2010 (See Backup Table 4)
<b>Unescalated Pile Replacement, \$/EA:</b>	<b>\$6,636.00</b>	
Temporary Dock Relocation, \$/EA:	\$89,173	cost developed by Anchor QEA, 2010 (See Backup Table 5)
<b>Unescalated Temporary Dock Relocation, \$/EA:</b>	<b>\$89,173.00</b>	
Debris Removal and Disposal, \$/EA:	\$11,630	cost developed by Anchor QEA, 2010 (See Backup Table 2), includes removal and disposal

**Made by/Received by:** Abby Broadstone

**Talked with:** Mark Krening at Chemical Waste Management of the Northwest (503-519-3959)

**Subject:** Subtitle C Transportation, Pretreatment and Disposal of Contaminated Sand/Sediment

**Distribution:** Scott Coffey, Gary Hazen, and Eleonora Borisova

**Discussion:**

**Standard Tipping Fee:** Standard tipping fee for Subtitle C is \$85/TN. This is for waste that does not require pretreatment or does not exceed LDRs.

**Treatment Costs:** Stabilization is typically used for heavy metal contamination, and solidification is typically used for non-hazardous waste. Based on the fact that the waste contains TCE, PAH, Benzene (D018), and listed wastes (F002 and F027), we will need thermal desorption with organic recovery unit. The costs for thermal desorption treatment is in the range of \$315/TN and \$565/TN based on concentration and moisture content. This cost is based on the minimum volumes, those estimated for Alt B. There may be some cost savings based on volumes of waste.

Note: At the Arlington Facility they cannot accept Dioxin/Furan contamination with concentrations above treatment standards of 1 (typical of F027 wastes). This waste would have to go to Canada for incineration. This was not communicated with vendor, but note that the RPAC Outfall (F027) Waste concentrations of TCDDs do not exceed the 1 ug/kg treatment standard, total TCDFs were detected offshore of the RPAC outfall in two samples at 3.878 and 3.614 ug/kg.

**Transportation Costs:** Truck transport costs from Portland are approximately \$45/TN with up to 34 TN/truckload. Rail transportation from Portland does not provide costs savings compared to truck transport. Barge costs may provide some cost savings based on bulk volume efficiencies; however, there is not a Port in Arlington. The barge will need to unload at the Port of Morral and trucked to Chemical Waste Management in Arlington. Barge costs are site-specific and dependent on location.

**Subject:** RE: Pricing for Disposal of Sediments at Roosevelt Landfill

Ok, if we assume you would be responsible for the transload of the dredge sediment and we would be responsible for transport and disposal from the Portland Area and we would use rail there- \$55.00 per ton plus the **Portland Metro Taxes (which is \$ 3.50 per ton.**

**If we offload barges at SDS in Bingen-** where we would be responsible for transload, transport and disposal **-\$70.00 per ton plus the Portland Metro Taxes.**

When you have more information I can work on the numbers but the above is a good estimate.

Leslie

**From:** John Collins <jcollins@aquablok.com>  
**Sent:** Tuesday, July 21, 2015 11:13 AM  
**To:** Broadstone, Abby  
**Cc:** Nielsen, Justin C.  
**Subject:** RE: CDM Smith Aquagate Sand Mixture Quote

Abby,

Thanks for the call, glad to get into the discussion.

Per our call, we can offer two products that meet the 0.12lb/SF/cm objective. These are as follows:

**AquaGate+PAC 5%** - \$385/CY (1,944lb of material at \$400/ton) – This product would constitute 94.7% of a CY in volume, so only a small amount sand/aggregate would be required to fill out the CY volume.

**AquaGate+PAC 10%** - \$220/CY (972lb of material at \$450/ton) – This product would constitute 48.6% of a CY in volume, so the balance of the volume would need a sand/aggregate mixture.

In regard to the 0.48lb/CF/cm carbon loading (which equates to 1.22lb/SF/Inch), AquaBlok does not have a carbon amended product that can meet this loading. However, for comparison, our AquaGate+PAC 10% material will provide a loading of 0.616lb/SF/Inch in carbon loading – which is approximately one half of this requested target loading. The pricing for this material at maximum loading is based on our nominal bulk density of 74lb/CF – or approximately 2,000lb per CY - \$450/CY (which is also almost exactly the price per ton).

As we discussed, I would question the 0.48lb/SF/cm loading, as this is very high compared to most activated carbon applications we have seen in the industry. It would be appreciated if we would have a further opportunity to discuss the need for this high loading level.

Please give me a call if you want to discuss or review the above.

Thanks, John

**Subject:** AquaBlok

Scott, attached is a summary of my conversation with John Collins yesterday.

Eric

On December 17, 2015, I spoke to John Collins of AquaBlok about application of AquaBlok to contaminated sediments beneath docks and similar structures.

AquaBlok is a low permeability material that is typically used in capping. Three questions must be answered when considering placement of AquaBlok – will it stay there when placed, will it mix with the sediments, will it move over time. Two physical conditions that can limit application of AquaBlok are placement on steep slopes and in high energy environments.

Typically, AquaBlok is placed with some sort of cover (sand, armor stone) to ensure that it remains in place.

The material can be placed under dock structures using telebelts or similar equipment. AquaBlok conducted a pilot study that involved placement of AquaGate material underneath dock structures at the Bremerton Naval Base in Washington.

Typically, a 6" hydrated layer of AquaBlok is required. This requires a dry placement thickness of 4" (hydrated thickness is typically 50% to 100% greater than dry thickness).

4.2" of thickness requires 30 lb per square foot at a density of 85 lb per cubic foot. The cost of AquaBlok is \$200 per ton or \$3.00 per square foot at 30 lb per square foot.

AquaBlok can be manufactured on site using the same manufacturing facility that would be used for manufacture of AquaGate. This reduces transportation costs. Approximately 2 acres of land with large buildings for weather protection is required.

Table 24. Upland Subtitle D Landfill Disposal Cost Buildup

Task	Unit	Quantity	Unit Cost	Total Cost	Basis/Notes
<b>Transload Facility Development</b>					
Transload facility permitting	LS	1	\$40,000	\$5,000	(1); Based on past experience normalized over total landfill disposal volume
Transload facility development	LS	1	\$7,500,000	\$863,000	(1,2); One time cost normalized over total estimated landfill disposal volume
Yearly property lease rate	ACRE	20	\$23,500	\$470,000	(3); Lease rate based on Port of Portland T6 public records.
Yearly gondola mobilization	Cars	500	\$4,000	\$2,000,000	(4); Car mobilization price from Waste Management
<b>Materials Handling and Stabilization</b>					
Materials handling from barge to upland stockpile	TON	345,000	\$6	\$2,070,000	(5); Offloading rate based on crane on dock and off-road trucks hauling to stockpile
Purchase Diatomaceous Earth (DE)	TON	17,250	\$94	\$1,622,000	Assumed 5% by weight mixing rate. DE price from Waste Management
Mix DE with dredged material to improve handling	TON	17,250	\$2	\$35,000	Cost based on end loader mixing DE and dredge material
Materials handling from stockpile to rail cars	TON	362,250	\$5	\$1,811,000	Cost assumes end loaders loading to rail cars on each side of stockpiles
Water treatment	1,000 gal	7,500	\$10	\$75,000	(6); Water treatment cost based on recent construction project.
<b>Transportation and Disposal</b>					
Rail transportation and tipping fee at Subtitle D landfill	TON	362,250	\$50	\$18,113,000	Price from Waste Management for unit train service.
<b>Inspection and Monitoring of Transload Facility</b>					
Labor inspections during operations	FTE	2.5	\$75,000	\$188,000	Assumes 7 people during 4 months of dredging and 1 during subsequent 2 months
Environmental monitoring direct costs during offloading	MONTH	4	\$15,000	\$60,000	Cost for boat, monitoring equipment and chemistry analysis
Reporting	Year	1	\$40,000	\$40,000	Based on past experience
<b>Total Estimated Cost</b>				<b>\$27,352,000</b>	
<b>Total Cubic Yards Handled Per Season</b>				<b>230,000</b>	(7)
<b>Total Tons Handled Per Season</b>				<b>345,000</b>	Assumes 1.5 tons/cy unit weight
<b>Estimated Cost Per Cubic Yard</b>				<b>\$119</b>	
<b>Estimated Cost Per Ton</b>				<b>\$79</b>	

**Notes:**

- (1) Assumed total dredge volume taken to upland landfill through life of facility: 2,000,000 cy  
 Alts B&C - ~200,000 to 1,260,000 cy (w/o in-water); 0 to 600,000 cy (w/ in-water)  
 Alts D&E - ~440,000 to 2,300,000 cy (w/o in-water); 0 to 600,000 cy (w/ in-water)  
 Alt F - ~2,200,000 to 6,698,000 cy (w/o in-water); 0 to 4,305,000 cy (w/ in-water)
- (2) Assumption for site development:  
 Pier/dock structure development/upgrade (~\$1.5M)  
 -Addition of ~10,000 feet of new rail line & ~5 switches (~\$3.5M)  
 Creation of 12 to 15 acres of bermed stockpile areas holding up to 70,000 cy of sediment (~\$1M)  
 Mobilization of offloading equipment, off-road trucks, end loaders and other equipment (~\$0.5M)  
 Miscellaneous site improvements (utilities, water treatment, offices, etc.) (~\$1M)
- (3) Assumed another ~5 acres for support activities for total site need of 20 acres. Lease rate is yearly.
- (4) Assuming 3,000 to 5,000 tons/day loaded out, 100 tons/gondola, and 10-day turnaround produces 300 to 500 rail cars needed each year.
- (5) Assumes 230,000 cy/season and 1.5 tons/cy weight conversion.
- (6) Assumes 15-acre stockpile receiving 37 inches/year of rain over the 6-month stockpile time.
- (7) Assumes for transload volume per year:  
 -85 to 105 days of dredging (5 to 6 days/week) in a 120-day construction window  
 -700 cy/day/site and 2 to 3 cleanup sites being dredged at one time  
 - 10 to 15 acres of 5-foot stockpiles can hold between 70,000 and 120,000 cy for shipping to the landfill after the dredging season is complete.

*The following terms will apply to material purchased at Knife River for this project:*

1. Prices include standard ODOT quality control and process control tests at the plant during production of the above quoted product(s). Acceptance of materials supplied by Knife River is at the plant at the time of production.
2. All gradations per ODOT specifications unless otherwise stated. Materials contain natural moisture only.
3. Credit terms net 15th of month following invoice.
4. Prices are for all materials and dump sites quoted inclusive.
5. Per ton pricing is based upon full load deliveries. Short loads are priced at truck time plus materials.
6. Knife River will attempt to secure adequate trucking with a minimum of 48 hours notice.
7. If applicable, dump site agreement must be signed before any export will be accepted.
8. Conversion rates & proctors are for information only & shall not be used to determine pay quantities.
9. No retainage of any material purchased.

---

**Remarks:**

1. PRICING IS FOR BUDGET PURPOSES.
2. KNIFE RIVER HAS A BARGE LOAD OUT FACILITY IF BARGING MATERIAL IS AN OPTION.
3. THE PRICE TO RENT KNIFE RIVER'S 6000 TON BARGE, KR-1, IS \$500 PER HOUR. THIS DOES NOT INCLUDE A TUGBOAT.
4. WE WILL LOAD THE ABOVE MATERIAL FROM THE REICHOLD SOURCE ONTO THE CUSTOMER'S BARGE FOR A FEE OF \$0.50 PER TON.
5. THE RATE AT WHICH WE LOAD KR-1 IS 1500 TONS PER HOUR. IF NEEDED, KNIFE RIVER WILL BACK THAT SPEED DOWN TO 1000 TONS PER HOUR TO ACCOMMODATE THE CUSTOMER'S BARGES LOADING CAPABILITY.

**Description:** Determination of base wage rates for general construction personnel (i.e., labor, equipment operators, etc.). Wage rates based on Foreign Labor Certification (FLC) Data Center Online Wage Library (flcdatacenter.com) or base wage rates from Davis-Bacon determinations for Multnomah County, Oregon obtained February 2016. Fringe rates were assumed where Davis-Bacon determination did not set fringe rates. Payroll taxes and insurance are included in the MII estimate calculations.

**Craft Labor Rates**

Wildlands Inc - Alder Creek Restoration Project, Multnomah County, OR <sup>4,5</sup>	-	-	\$75,000	14.34	\$1,075,500.00	2014	-	\$1,091,056	Agreement for Purchase and Sale of Discounted Acre-Year Credits and Escrow Instructions (Alder Creek-City of Portland). City of Portland Ordinance No. 186911
A Primer on Habitat Project Costs - Estuary Restoration Matrix Cost Range <sup>6</sup> (Evergreen Funding Consultants 2003)	\$1,050,000	1	-	-	\$1,050,000.00	2003	\$1,616,122	\$1,616,122	A Primer on Habitat Project Costs (Evergreen Funding Consultants 2003). Used the middle of cost range for "Highly Developed" Land Use and "Moderate/Average" Extent of Earthmoving.
							<b>Revised Average Unit Cost (2016):</b>	<b>\$1,070,827</b>	

Notes:

Mitigation costs were escalated from the year of construction to 2016. The weighted average composite indices from USACE Civil Works Construction Cost Index System (CWCCIS), EM 1110-2-1304, revised 31 March 2012 and amended 30 September 2015 was used to determine the escalation rate to the base year of the current estimate (2016).

Mitigation costs for the McCormick & Baxter Superfund Site were excluded from the analysis as of 2/9/16 because costs for mitigation were not quantified per discussion with DEQ.

<sup>1</sup> - For projects where the construction year was not specified, costs were assumed to be current as of the year the source document was produced.

<sup>2</sup> - The cost presented in Table 6.1-4 of the Appendix M, Attachment 1, Anchor QEA FS (2010) for this item is \$885,581, as shown in the table above. However, the actual costs present in A Primer on Habitat Project Cost is \$885,817.

<sup>3</sup> - The cost presented in Table 6.1-4 of the Appendix M, Attachment 1, Anchor QEA FS (2010) for this item used the high end of cost range for "Somewhat Developed" Land Use and "Moderate/Average" Extent of Earthmoving. This cost is likely underestimating the cost of mitigation, as the Portland Harbor Site should be classified as "Highly Developed". See footnote 6.

<sup>4</sup> - Costs for the Alder Creek Restoration project are based on DSAY (discounted service-acre year) credits as opposed to acreage because it was for NRDA mitigation. Because the acreage and total project cost does not reflect in the calculation, it is not presented for purposes of this table.

<sup>5</sup> - Based on the Habitat Equivalency Analysis method used to evaluate the Alder Creek Restoration project, it is expected that 14.34 DSAY credits will be generated per acre. Therefore, a conversion factor of 14.34 DSAYs/AC was used to convert the unit cost of \$/DSAY to \$/AC.

<sup>6</sup> - Due to Table 6.1-4 of the Appendix M, Attachment 1, Anchor QEA FS (2010) likely underestimating the cost of mitigation, as discussed in footnote 3, a separate cost was included from the A Primer on Habitat Project Costs - Estuary Restoration Matrix Cost Range. This cost used the middle of cost range for "Highly Developed" Land Use and "Moderate/Average" Extent of Earthmoving.

**APPENDIX J - UPDATE**

**Calculation of Residual and Post  
Construction Risk Estimates**

## J1. CALCULATION OF RESIDUAL RISK ESTIMATES

Residual risk is defined as the cancer risk or HI once the PRGs are achieved. Because not all selected PRGs are risk-based, the residual risk or HQ for individual COCs may be greater than the  $1 \times 10^{-6}$  cancer risk or HQ of 1 used to calculate risk-based PRGs.

The residual risk for RAO 1 was calculated as the ratio of the carcinogenic risk-based PRGs and the selected PRG values presented in Table 2.2-4 using the following equation:

$$Residual\ risk = \sum_{n=a}^n \frac{S - PRG_n}{R - PRG_n} \times 10^{-6} \quad \text{Equation J1-1}$$

Where S-PRG<sub>a</sub> and R-PRG<sub>a</sub> represent the selected- and risk-based PRGs, respectively, for each COC in sediment. Residual risks and HIs for RAO 1 are presented in **Table J1-1**.

The residual risk for RAO 2 was calculated as the ratio of the average tissue concentration in fish for the selected sediment PRGs and the risk-based fish tissue concentrations. The selected average tissue concentrations were derived from the FWM using the methodology described in Appendix B, assuming a surface water concentration for each COC equal its respective water quality criterion (see RAO 3 PRGs). The risk-based tissue PRGs are presented in Table B3-5. This comparison was conducted using the following equations:

$$Residual\ risk = \sum_{n=a}^n \frac{Tissue\ Conc_{PRG-based}}{Tissue\ Conc_{Risk-based}} \times 10^{-6} \quad \text{Equation J1-2}$$

$$Residual\ HI = \sum_{n=a}^n \frac{Tissue\ Conc_{PRG-based}}{Tissue\ Conc_{Risk-based}} \quad \text{Equation J1-3}$$

Residual risks and HIs on a Site-wide scale were calculated using the risk-based tissue PRGs assuming consumption rate of 142 g/day, residual risks and HIs on a river-mile and SDU scale were calculated using the tissue PRGs assuming a consumption rate of 49 g/day. Residual risks and HIs for RAO 2 are presented in **Table J1-2**.

Residual HQs for RAO 6 were calculated as the ratio of the selected PRG and the risk-based PRG for each COC from Table 2.2-9 and using the following equation:

$$Residual\ HQ = \frac{F - PRG}{R - PRG} \quad \text{Equation J1-4}$$

The PRGs presented in Table 2.2-9 are COC-specific, but are not species-specific. For example, the PRG for PCBs is based on mink via dietary exposure from consumption of fish and shellfish, while the PRG for DDX is based on the Sandpiper via dietary exposure from consumption of invertebrates. For this reason, each COC was evaluated separately and exposures were not considered additive, and the HQ for each COC evaluated separately. Residual HQs for RAO 6 are presented in **Table J1-3**.

## **J2. CALCULATION OF POST-CONSTRUCTION RISK ESTIMATES**

---

Post-construction risks were calculated for RAOs 1, 2, 4, 5, 6 and 8 for each for each alternative carried through the detailed analysis. These evaluations required estimates of surface sediment concentrations averaged on the following spatial scales: rolling river mile concentrations averaged over 0.5 river miles for only the eastern and western nearshore river segments and Swan Island Lagoon, rolling river mile average concentrations for each river segment, SDU-scale SWACs, and a site-wide weighted average concentration for each COC. All post-construction risks are evaluated as only the contribution from the sediment.

### **J2.1 POST-CONSTRUCTION SEDIMENT CONCENTRATIONS**

---

Surface sediment concentrations on a rolling river mile scale were calculated by averaging surface sediment concentrations over a distance of 0.5 miles (RAO 1) or 1 mile (RAOs 2 and 6) in successive 0.1 mile increments in both the east and west nearshore segments, and the navigation channel. A 0.5 mile average concentration for RAO 1 is consistent with the exposure area evaluated for exposure to sediment used in the BHHRA. A 1 mile average concentrations was used for RAOs 2 and 6, consistent with the assumptions used to evaluate consumption of fish in the BHHRA and of prey by ecological receptors in the BERA. Concentrations averaged on an SDU scale are approximate to a 1 river mile scale, thus evaluations on an SDU scale for RAOs 2 and 6 are consistent with the exposure assumptions used in the risk assessments.

A site-wide evaluation was also used for RAO 2, consistent with the RME evaluation for subsistence fishers in the BHHRA. Site-wide sediment concentrations were calculated for RAO 2 using the post remedial SWACs based on the average concentrations of each pixel over the entire Site-wide area.

### **J2.2 POST-CONSTRUCTION RISK ESTIMATES FOR RAO 1**

---

Cancer risks for RAO 1 were calculated using the rolling river mile concentrations averaged on a 0.5 mile scale and the sediment PRGs for each COC based on a  $1 \times 10^{-6}$  cancer risk, using the following equation:

$$\text{Cancer risk} = \left( \frac{\text{Conc}_a}{\text{PRG}_a} + \frac{\text{Conc}_b}{\text{PRG}_b} + \frac{\text{Conc}_c}{\text{PRG}_c} + \dots + \frac{\text{Conc}_i}{\text{PRG}_i} \right) \times 10^{-6} \quad \text{Equation J2-1}$$

The cancer risk was calculated from each 0.1 mile incremental average surface concentration for each COC. Direct contact with sediment in the navigation channel segment was not evaluated for this RAO. Rolling river mile COC concentrations averaged on a 0.5 river mile scale are presented in **Tables J2.2-1a-d**, post-construction

cancer risks for RAO 1 are presented in **Tables J2.2-2a-e**. Residual non-cancer hazard for RAO 1 was not evaluated, as there are no PRGs for RAO 1 COCs based on non-cancer effects.

### **J2.3 POST-CONSTRUCTION RISK ESTIMATES FOR RAO 2**

Post-construction risks for RAO 2 were estimated on a on a site-wide basis, a rolling river mile scale (1-mile average concentration), and by SDU. Site-wide post-construction risks were calculated using the site-wide weighted average sediment concentrations calculated for each COC (see Section J2). These sediment concentrations were input into the FWM (Appendix B1) to calculate COC concentrations in tissue. Surface water concentrations in this analysis was set to zero in order to directly assess the contribution from post-construction sediment concentrations on the post-construction risk estimate. COC concentrations in fillet tissue were calculated using the fillet-whole body concentration ratios presented in Appendix B3 (Table B3-3), and a mean exposure concentration was calculated as the average of fillet concentration in sculpin, largescale sucker, carp, and smallmouth bass (with largescale sucker as a surrogate for brown bullhead and sculpin as a surrogate for black crappie). Post-construction cancer risks and noncancer HIs were calculated using the same equations used for residual risk (equations J1-2 and J1-3, respectively). The risk-based tissue PRGs presented in Table B3-5 assuming a consumption rate of 142 g/day were used for this evaluation. Post-construction risk and hazard estimates are presented in **Tables J2.3-1a-g**.

Post-construction risks on a rolling river mile and SDU scale were calculated using the sediment PRGs based on a consumption rate of 49 g/day (Table B3-5), using the following equation:

$$Cancer\ risk = \left( \frac{Conc_a}{PRG_a} + \frac{Conc_b}{PRG_b} + \frac{Conc_c}{PRG_c} + \dots + \frac{Conc_i}{PRG_i} \right) \times 10^{-6} \quad \text{Equation J2-2}$$

Noncancer hazard was calculated using the sediment PRGs presented in Table 2.2-5 for the child or infant the following equation:

$$Hazard\ Index = \left( \frac{Conc_a}{PRG_a} + \frac{Conc_b}{PRG_b} + \frac{Conc_c}{PRG_c} + \dots + \frac{Conc_i}{PRG_i} \right) \quad \text{Equation J2-3}$$

Post construction risks were calculated for 0.1 mile incremental average surface concentration for each COC. Concentrations averaged on a 1 river mile scale are presented in **Tables J2.3-2a-m** Site-wide post-construction risk estimates for individual COCs are presented in **Tables J2.3-3a-k** (cancer risk), **Tables J2.3-4a-j** (noncancer HI), and **Tables J2.3-5a-g** (noncancer HI-infant). Cumulative post-construction risk and HI estimates are presented in **Tables J2.3-6a-c**.

Post-construction COC concentrations on an SDU scale are presented in **Table J2.3-7**. Post-construction risk estimates for individual COCs and cumulative risks on an SDU scale are presented in **Tables J2.3-8a-b** (cancer risk), **Tables J2.3-9a-b** (noncancer HI), and **Tables J2.3-10a-b** (noncancer HI-infant).

#### **J2.4 RESIDUAL RISK ESTIMATES FOR RAO 5**

---

The evaluation of risk reduction for RAO 5 was conducted using the results of the CBRA footprint (see Appendix D11 and Figure 4.1-1) and the GIS layers for each Alternative. To account for population level risk, the analysis also identified areas where the sediment concentration exceeded PRGs for RAO 5 by factors of 10 and 100 (**Figures J2.4-1** and **J2.4-2**). These areas were compared to the remedial footprint for each alternative and the area of overlap calculated. These results are presented in **Figures J2.4-3a-f** and in **Table J2.4-1**.

#### **J2.5 POST-CONSTRUCTION RISK ESTIMATES FOR RAO 6**

---

Post-construction HQs for RAO 6 were estimated on a rolling river mile scale (1-mile) and an SDU scale using the sediment PRGs presented in Table 2.2-9 using the following equation:

$$\text{Hazard Quotient} = \frac{\text{Conc}_a}{\text{PRG}_a} \quad \text{Equation J2-4}$$

Post construction risks were calculated for 0.1 mile incremental average surface concentration for each COC. Post-construction HQs on a rolling-river mile scale are presented in **Tables J2.5-1a-i** and on an SDU scale in **Table J2.5-2**.

#### **J2.6 POST-CONSTRUCTION RISK ESTIMATES FOR RAOS 4 AND 8**

---

The evaluation of risk reduction for RAOs 4 and 8 was conducted using the results of the contaminated groundwater footprint (see Figure 1.2-19) and the GIS layers for each Alternative. These areas were compared for each alternative and the area of overlap calculated. These results are presented in **Figures J2.6-1a-f** and in **Table J2.6-1**.
