## MEMORANDUM

**Date:** April 8, 2010  
**To:** Minesh Patel, Permit Section  
**From:** Matthew Harrell, Air Quality Planning Section *Mutt*  
**Subject:** Vulcan-Manteno PSD Updates (091806AAB - Construction Permit 96020014)

### Background

The purpose of this memorandum is to address a couple of issues raised by the Permit Section related to the Vulcan-Manteno project and final issuance of its current construction permit. The first issue involves updating Vulcan's Full Impact Analysis results for 24-hour PM<sub>10</sub>. The second issue is the preparation of a conservative estimate of 1-hour NO<sub>2</sub> impacts from the lime kiln in anticipation of USEPA's new 1-hour NO<sub>2</sub> standard.

### Updated 24-hour PM<sub>10</sub> Full Impact Analysis Results

Vulcan's 2006 Full Impact Analysis results for 24-hour PM<sub>10</sub> were reevaluated after the background count for the Midlothian monitor was updated from 2004-2006 to 2007-2009. Between 2006 and 2009 the background count for this monitor increased from 52 ug/m<sup>3</sup> to 54 ug/m<sup>3</sup>. This change pushed Vulcan's Full Impact Analysis results slightly over the standard of 150 ug/m<sup>3</sup>.

The highest 6<sup>th</sup> high receptor from the 2006 modeling was examined further and it was determined that its concentration of 96.81 ug/m<sup>3</sup> was primarily related to three background sources at North Central Materials (091806AAJ) located northwest of the Vulcan lime kiln. Vulcan's highest significant impact at this receptor was 1.31 ug/m<sup>3</sup>, which is well below the significant impact level of 5 ug/m<sup>3</sup>. Closer inspection of the three sources at the North Central Materials facility showed that the emission rate for the Screening process was based on Total Suspended Particles (TSP), not PM<sub>10</sub>. As a result, emissions from this background facility were grossly overestimated.

The Inventory and Data Support Unit examined the data for North Central Materials and provided corrected PM<sub>10</sub> emissions for all three background sources: P135, P136, and

Marion • 2309 W. Main St., Suite 116, Marion, IL 62959 • (618) 993-7200

P137. Emissions for P135 decreased from 3.788 to 3.34 lbs/hour. Emissions for P136 decreased from 11.41 to 3.83 lbs/hour, while emissions for P137 increased from 1.24 to 1.82 lbs/hour. The 2006 24-hour PM<sub>10</sub> Full Impact Analysis model was re-run using these updated emission values and the concentration at the critical receptor dropped to 56.81 ug/m<sup>3</sup>. The highest 6<sup>th</sup> high concentration is now 89.02 ug/m<sup>3</sup>. When this value is added to the 2007-2009 background count of 54 ug/m<sup>3</sup>, the resulting model design concentration is 143.02 ug/m<sup>3</sup>, which is below the 24-hour PM<sub>10</sub> standard of 150 ug/m<sup>3</sup>.

#### Estimated Maximum 1-hour NO<sub>2</sub> Impact from the Lime Kiln

USEPA will soon promulgate a new 1-hour standard for NO<sub>2</sub> of 100 parts per billion (ppb). The Permit Section requested that the Modeling Unit prepare an estimate of the lime kiln's potential 1-hour NO<sub>2</sub> impact based on currently available data. This was accomplished by using the 2009 1-hour CO significant impact results to create a scaling factor for NO<sub>x</sub>. The lime kiln's annual NO<sub>x</sub> emission rate of 243 lbs/hour is actually based on a peak short-term value. Thus, this emission rate can be scaled using the 1-hour CO significant impact data to produce a reasonable estimate of the peak short term NO<sub>x</sub> impact from the lime kiln as shown below:

1-hour CO emission rate: 620 lbs/hour

1-hour CO maximum significant impact concentration: 328.3 ug/m<sup>3</sup>

Estimate of 1-hour NO<sub>x</sub> maximum significant impact concentration:

$620 \text{ lbs/hour CO} / 328.3 \text{ ug/m}^3 \text{ CO} = 243 \text{ lbs/hour NO}_x / x \text{ ug/m}^3 \text{ NO}_x$ ,  
or,  $x = 128.67 \text{ ug/m}^3 \text{ NO}_x$

$1 \text{ ug/m}^3 \text{ of NO}_x = 0.53 \text{ ppb}$ ; thus,  $128.67 \text{ ug/m}^3 \text{ NO}_x \times 0.53 = 68.2 \text{ ppb NO}_x$

This estimate is doubly conservative. First, it assumes that all NO<sub>x</sub> consists of NO<sub>2</sub> (it is usually assumed that only 75% of NO<sub>x</sub> consists of NO<sub>2</sub>). Second, compliance with the new standard is based on the average of the 8<sup>th</sup> highest (98<sup>th</sup> percentile) daily maximum values over three years, not a single highest 1<sup>st</sup> high hourly concentration value. Therefore, it is highly unlikely that operation of the lime kiln will cause a violation of the new 1-hour NO<sub>2</sub> standard.
