Attn: TSCA Docket Clerk

Re: For Your Information Submission:

The enclosed information is submitted on behalf of Dow Corning Corporation, Midland, Michigan, 48686-0994, on a For-Your-Information (FYI) basis as a follow-up to submissions made concerning octamethylcyclotetrasiloxane (OMCTS), which chemical substance was the subject of a health and safety data rule issued under Section 8(d) of the Toxic Substances Control Act (TSCA) and with an effective date of December 28, 1984 (sunset date December 28, 1994), as codified at 40 CFR 716 (Health and Safety Data Reporting). The information presented in this submission was generated as part of our Siloxane Research Program. This program was the subject of a memorandum of understanding, dated April 9, 1996, between Dow Corning and EPA.

Listed Chemical Substance:

556-67-2 Octamethylcyclotetrasiloxane (OMCTS, D_4)

Final Study Report:

An Inhalation F_1 Generation Reproductive Toxicity Study of Octamethylcyclotetrasiloxane (D_4) in Female Sprague-Dawley Rats

TECHNICAL REPORT

WIL Research Laboratories, LLC
1407 George Road
Ashland, Ohio 44805

Report No.:	2004-I0000-54361
Title:	An Inhalation F_1 Generation Reproductive Toxicity Study of Octamethylcyclotetrasiloxane (D_4) in Female Sprague-Dawley Rats
Study No.:	9621
External Testing Facility No.:	WIL-51086
Test Article:	Octamethylcyclotetrasiloxane (D_4)
Study Director:	Donald G. Stump, Ph.D., D.A.B.T. Associate Director, Developmental and Reproductive Toxicology
Sponsor:	Dow Corning Corporation 2200 W. Salzburg Road Midland, Michigan 48686-0994
Sponsor Representative:	Waheed H. Siddiqui, Ph.D. Associate Toxicology Scientist
Testing Facility:	WIL Research Laboratories, LLC 1407 George Road Ashland, Ohio 44805
Study Completion Date:	January 17, 2005
Security Statement:	This report may be reproduced and shared with any Dow Corning employee. The director of the issuing department must approve distribution outside the corporation. When this INTERNAL report is no longer needed, it must be destroyed in a manner that safeguards against unauthorized disclosure.

J. Study Protocol 2251

1. ABSTRACT

This study was conducted to gain mechanistic insights on the reproductive toxicity in F_1 generation Sprague-Dawley rats exposed to octamethylcyclotetrasiloxane (D_4) during different windows of development. In a previous two-generation reproductive toxicity whole-body inhalation study of D_4[1], reduced fertility was observed for F_1 females exposed at 700 ppm. Although the males used for these matings were exposed to the test article, a further mating of these males to naive females showed no fertility effect on the males, thereby demonstrating the reduced fertility was a female-specific phenomenon. No significant effect on fertility was observed in the F_0 generation, in which no *in utero*/nursing exposure occurred and direct exposures initiated at approximately 6 weeks of age. Therefore, the current study employed exposed females and unexposed males and focused on the F_1 generation. The F_0 parental animals were mated once to produce the F_1 generation. F_1 parental animals were mated twice to replicate the design of the previous two-generation study.

Groups of female Crl:CD®(SD)IGS BR rats (30/group) were exposed to test article for 6 hours daily for at least 7 days prior to mating. The target test article concentration was 700 ppm; the mean measured exposure concentration was 704 ppm for the F_0 generation and 706 ppm for the F_1 generation. The exposure regimen was as follows:

- Group 1 (filtered air control group) females were exposed to filtered air only throughout the study in the F_0 and F_1 generations. Exposure of the F_0 and F_1 females continued throughout mating and gestation through gestation day 20. Exposure of the F_0 females was re-initiated on lactation day 5 and continued through lactation day 20. Exposure of the F_1 females was re-initiated on lactation day 5 and continued throughout the second F_1 mating and gestation periods through gestation day 20.
- Group 2 (designated as 700/700-D22 ppm for reporting purposes) females were exposed to D_4 throughout the study; this group was included to replicate the conditions that were used previously and that were demonstrated to cause adverse effects on fertility. The F_0 generation was exposed as described for Group 1, and the F_1 generation was exposed to D_4 beginning on postnatal day (PND) 22 and continuing through two mating periods as described for Group 1.

- Group 3 (designated as 700/700-D44 ppm for reporting purposes) females were exposed to D_4 throughout the study. The F_0 generation was exposed as described for Group 2, and the F_1 generation was exposed to D_4 beginning on PND 44 and continuing through two mating periods as described for Group 2. This group was added to investigate the potential differences between starting the F_1 exposures at approximately 6 weeks of age versus 3 weeks of age.

- Group 4 (designated as 700/0 ppm for reporting purposes) females were exposed to D_4 during the entire F_0 generation as described for Group 2; however, F_1 animals were only exposed to filtered air throughout both mating periods. This group was added to investigate if the previously observed fertility effect was associated with indirect test article exposure of the F_1 animals *in utero* and during lactation.

- Group 5 (designated as 0/700 ppm for reporting purposes) females were exposed to filtered air during the F_0 generation; F_1 offspring were exposed to D_4 at weaning (PND 22) through both mating periods. This group was added to investigate the effects on fertility when F_1 exposures were initiated at 3 weeks of age and in the absence of any parental and potential *in utero* and nursing exposure to the test article.

All animals were observed twice daily for appearance and behavior. Clinical observations, body weights and food consumption were recorded at appropriate intervals prior to mating and during gestation and lactation. A detailed physical examination was conducted weekly. All F_0 females were allowed to deliver and rear their pups until weaning on lactation day 21. All F_1 females were allowed to deliver and rear their pups until weaning on lactation day 21 for the first mating period and until PND 4 for the second mating period. Offspring (30/sex/group) from the pairing of the F_0 animals were selected to constitute the F_1 generation. Surplus F_1 pups were euthanized and discarded without examination on PND 21 or 28, and all F_{2a} and F_{2b} pups were euthanized and discarded without examination on PND 21 and 4, respectively. Gross necropsies were performed for F_1, F_{2a} and F_{2b} pups found dead or euthanized *in extremis*. All F_0 maternal animals received a gross necropsy following completion of weaning of the F_1 pups on PND 21, on post-cohabitation day 25, on post-mating day 25 or following total loss of their litter. All F_0 and F_1 males were euthanized and discarded following their respective mating periods. Following the second mating, all surviving F_1 females were necropsied on lactation day 4, on post-mating day 25, on post-cohabitation day 25 (25 days following

completion of the second breeding period) or following total loss of their litter. Selected organs were weighed from the F_0 and F_1 maternal animals. Serum was obtained from all F_1 females and analyzed for levels of estradiol, progesterone and prolactin. Designated reproductive tissues from all F_1 maternal animals were examined microscopically.

In addition, a pharmacokinetic phase was conducted concurrently with the main study; the following plasma samples were collected. Plasma, fat and liver samples were collected from six control and 700/700-D22 ppm group F_0 females following completion of exposure on gestation day 20 and from all fetuses from each dam in the control and 700/700-D22 ppm groups on gestation day 20. Plasma, fat and liver samples were also collected from five 700/700-D22 ppm group F_1 weanlings on PND 21 and from five 0/700 ppm group weanlings that were exposed to D_4 on PND 22-26. All samples were sent to Dow Corning Corporation for analysis of D_4.

In the current study, exposure of females to 700 ppm D_4 resulted in generally the same profile of reproductive toxicity that was demonstrated previously. In the previous two-generation study[1], adverse reproductive effects noted in the females exposed to 700 ppm D_4 included dystocia (F_0 generation), reduced fertility (F_1 generation) and reduced live litter size (F_0 and F_1 generations). In the current study, one and three F_1 females in the 700/700-D22 and 700/700-D44 ppm groups, respectively, died between gestation day 22 to lactation day 5 following the first mating period and one F_1 female in both the 700/700-D44 and 0/700 ppm groups died on lactation day 0 and on gestation day 23, respectively, following the second mating. Evaluation of the in-life and *postmortem* data for the F_1 females that died prior to scheduled euthanasia revealed that the deaths were likely related to dystocia. No mortality was observed in the F_0 generation.

Reductions in mean live litter sizes and mean number of pups born were observed in all groups of F_0 and F_1 females exposed to 700 ppm D_4 following all mating periods. The differences were statistically significant for the F_0 females, the F_1 females following the first mating period and only the F_1 females in the 0/700 ppm group following the second

mating period. As a result, increased (often statistically significant) mean offspring body weights were noted in all 700 ppm groups for the F_1 and F_{2a} offspring and 0/700 ppm group for the F_{2b} offspring. Offspring body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups from the F_{2a} generation were decreased during PND 4-7, 7-14 and 14-21. Postnatal survival was reduced (not statistically significant) from birth to PND 4 in the 700/700-D22 and 700/700-D44 ppm groups for the F_{2a} offspring and for the 700/700-D44 and 0/700 ppm groups for the F_{2b} offspring.

There were no adverse effects on mating and fertility indices in the F_0 generation. However, one and four F_0 females from the 700/700-D22 and 700/0 ppm groups, respectively, were in the process of total litter resorption at the time of euthanasia on post-mating day 25. In the F_1 generation, fertility indices (OECD and EPA methods of calculation) were reduced (not statistically significant) in the 700/700-D22 ppm group for both the first and second F_1 mating periods. Estrous cycle length in the F_1 700/700-D22 and 0/700 ppm groups was also increased (not statistically significant) when compared to the control group for the first mating period but was comparable for the second mating period. In addition, one F_1 female in both the 700/700-D22 and 700/700-D44 groups failed to deliver following the first mating period and was found to be gravid, and two, one and one F_1 females in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, failed to deliver following the second mating period and were found to be gravid.

No test article-related clinical or macroscopic findings were noted in either maternal generation. No test article-related microscopic findings or effects on reproductive organ weights were noted for any F_1 female group.

No clear exposure-related effects on mean estradiol, progesterone and prolactin levels were noted for F_1 females on lactation day 4. For F_1 females that failed to deliver, mean estradiol and progesterone levels were not affected by exposure; however, mean prolactin levels in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups were increased when compared to the control group. Estradiol/progesterone (E/P) ratios for F_1 females

on lactation day 4 in the D_4-exposed groups (700/700-D22, 700/700-D44 and 0/700 ppm groups) were increased compared to the groups receiving filtered air (0/0 and 700/0 ppm groups). The higher E/P ratios in the D_4-exposed F_1 females correlated with an increased number of females in these groups with no complete basophilic corpora lutea, indicating that these females were slower to begin cycling after parturition than the F_1 females exposed to filtered air. For females that failed to deliver, E/P ratios were highly variable among the 0/0, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups. However, in all groups (including the control group), the E/P ratios for females that failed to deliver were higher than for females in the same exposure groups that delivered. In addition, the majority of the F_1 females that failed to deliver in the D_4 exposure groups did not have basophilic complete corpora lutea and/or were cycling abnormally.

Concentrations of D_4 in the plasma, liver and fat samples of F_0 females exposed to 700 ppm beginning 7 days prior to mating through gestation day 20 demonstrated that exposure occurred. When expressed on a μg/g basis, D_4 levels in fat were approximately 13- and 74-fold higher than in the liver and plasma, respectively. D_4 levels in these same tissues were measurable following indirect exposure to gestation day 20 fetuses and PND 21 weanlings and following direct exposure to F_1 females on PND 22-26. In all cases, the highest offspring concentrations were observed in fat. For both fat and liver, the highest concentrations of D_4 were observed in the PND 22-26 exposed females followed by the gestation day 20 fetuses. In contrast, plasma D_4 levels were higher in the gestation day 20 fetuses than in the PND 22-26 exposed females. For all samples evaluated, the lowest levels were measured in the indirectly exposed PND 21 weanlings. The D_4 levels in the plasma, liver and fat were 4.8-, 1.5- and 4.7-fold lower, respectively, in the PND 22-26 exposed F_1 females than in the F_0 females.

While F_1 female exposure to D_4 clearly produced reproductive toxicity (decreased live litter size), it would appear that initiating direct exposure at 6 weeks of age instead of at 3 weeks of age resulted in slightly less toxicity as demonstrated by fertility rates in the 700/700-D44 ppm group that were similar to the control group while the fertility rates in

the 700/700-D22 and 0/700 ppm groups were slightly lower (but not statistically significant) than the control group. Additionally, exposure of D_4 only to the F_0 females (700/0 ppm group) resulted in no adverse reproductive effects for the F_1 females. The live litter size of F_1 females was reduced in the absence of F_0 maternal exposure (0/700 ppm group) to virtually the same extent as when exposures initiated in the F_0 females (700/700-D22 ppm group). Therefore, *in utero* exposure to D_4 is not required to produce an adverse female reproductive outcome.

2. GLP COMPLIANCE STATEMENT

This study, designated WIL-51086, was conducted in compliance with the United States Environmental Protection Agency (EPA) Good Laboratory Practice Standards (40 CFR Part 160), October 16, 1989; the United States Environmental Protection Agency (EPA) Good Laboratory Practice Standards (40 CFR Part 792), September 18, 1989; the standard operating procedures of WIL Research Laboratories, LLC, and the protocol as approved by the sponsor, with the following exceptions. The data for the pathology assessments conducted by Dr. Robert F. McConnell (Appendix H) were not collected according to Good Laboratory Practice Regulations; however, the pathology report was audited by the WIL Quality Assurance Unit. Data contained in the study records for the pathology assessments are copies of the original data.

While this is not a regulatory guideline study, the following components of this study are consistent with the United States Environmental Protection Agency (EPA) Health Effects Test Guideline OPPTS 870.3800, Reproduction and Fertility Effects, August 1998: species and strain, group size, use of litter-based statistics, mating procedure including vaginal cytology, and F_1 female exposure regimen.

* Audit was reissued

This study was inspected in accordance with the U.S. EPA Good Laboratory Practice Standards (40 CFR Parts 160 and 792), the standard operating procedures of WIL Research Laboratories, LLC, and the sponsor's protocol and protocol amendments with the following exceptions. The data located in Appendix F (Pharmacokinetic Report) were the responsibility of the sponsor. The data located in Appendix H (Pathology Report) were the responsibility of Robert F. McConnell, D.V.M., D.A.C.V.P., P.A., Consulting Pathology Services. Quality Assurance findings, derived from the inspections during the conduct of the study and from the inspections of the raw data and draft report, are documented and have been reported to the study director. A status report is submitted to management monthly.

This report accurately reflects the data generated during the study. The methods and procedures used in the study were those specified in the protocol, its amendments and the standard operating procedures of WIL Research Laboratories, LLC.

The raw data, the retention sample(s), if applicable, and the final report will be stored in the Archives at WIL Research Laboratories, LLC, or another location specified by the sponsor.

3.2. APPROVAL

This study was inspected according to the criteria discussed in Section 3.1.

7. OBJECTIVE

In a previous two-generation reproductive toxicity whole-body inhalation study of D_4[1], reduced fertility was observed for F_1 females exposed at 700 ppm. In that study, reduced fertility was observed for the first mating of the F_1 females following *in utero*/nursing exposure and approximately 15 weeks of direct exposure (10-week pre-mating period, 2-week mating period and 3-week gestation period). Direct test article exposure for these rats was initiated at approximately 3 weeks of age. A second mating of the F_1 generation was performed following an additional approximately 12 weeks of direct exposure (3-week lactation period, 4-week latent period, 2-week mating period and 3-week gestation period) which resulted in further reduced fertility. Although the males used for these matings were exposed to the test article, a further mating of these males to naive females showed no fertility effect on the males, thereby demonstrating the reduced fertility was a female-specific phenomenon. No significant effect on fertility was observed in the F_0 generation, in which no *in utero*/nursing exposure occurred and direct exposure was initiated at approximately 6 weeks of age. The current study employed exposed females and unexposed males and focused on the F_1 generation. Therefore, the primary objective of this study was to gain mechanistic insights on the reproductive toxicity in F_1 generation Sprague-Dawley rats exposed to octamethylcyclotetrasiloxane (D_4) during different windows of development.

For clarification of the terminology used to differentiate the generations in the report text, the offspring of the F_0 generation were defined as the F_1 litters. The offspring from the first mating of the F_1 generation were defined as the F_{2a} litters, and the offspring from the second mating of the F_1 generation were defined as the F_{2b} litters. Pups from the F_1 litters were selected to constitute the F_1 generation.

The route of administration was whole-body inhalation since this is a potential exposure pathway for humans. The animal model, the Crl:CD®(SD)IGS BR rat, is recognized as appropriate for multigeneration studies[2] and was selected based on the availability of

historical control data and because of its proven susceptibility to the effects of reproductive and developmental toxicants.

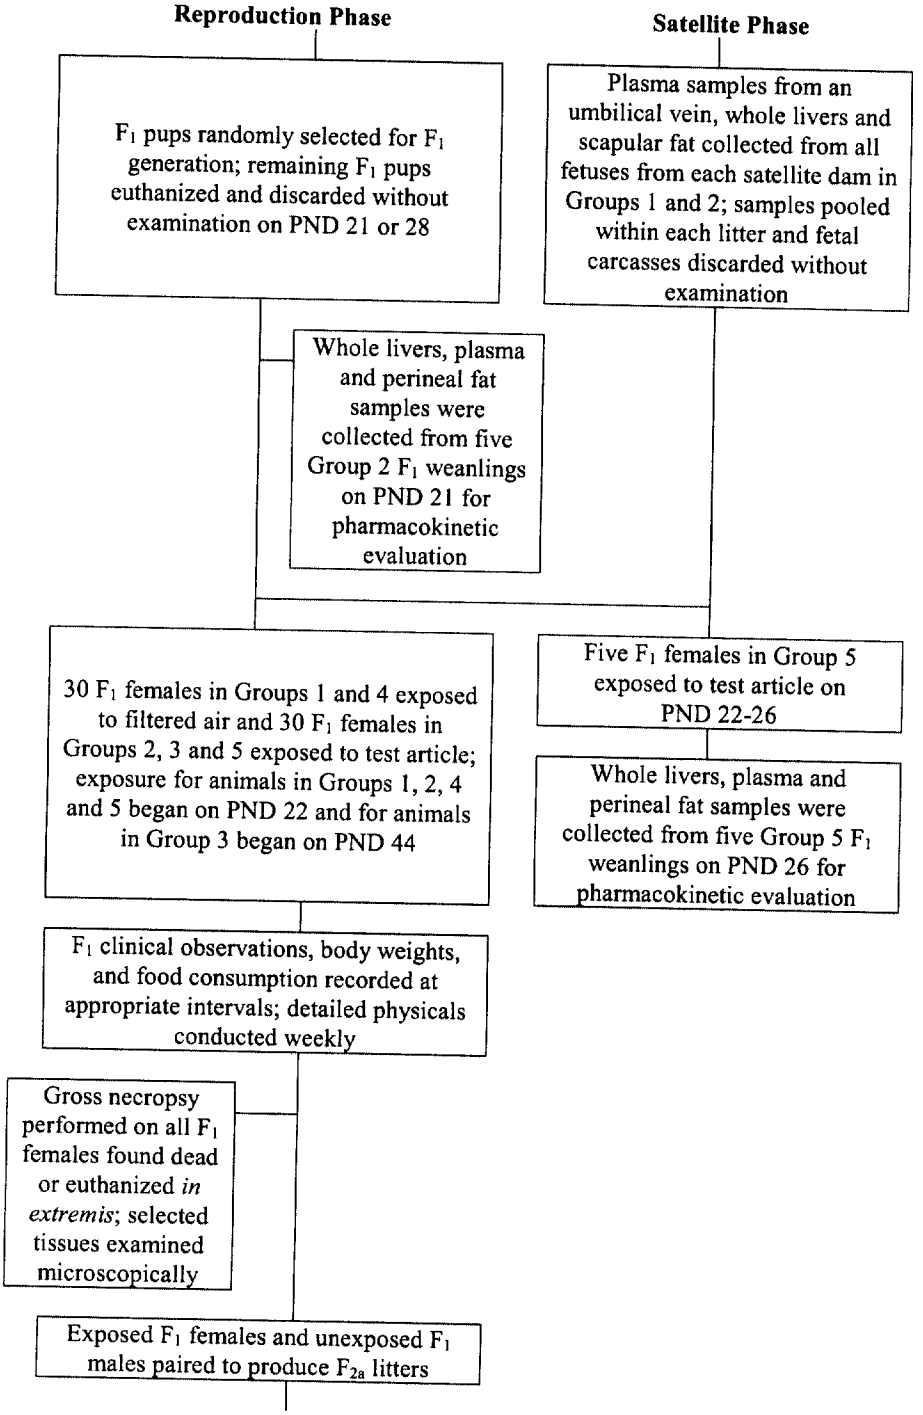
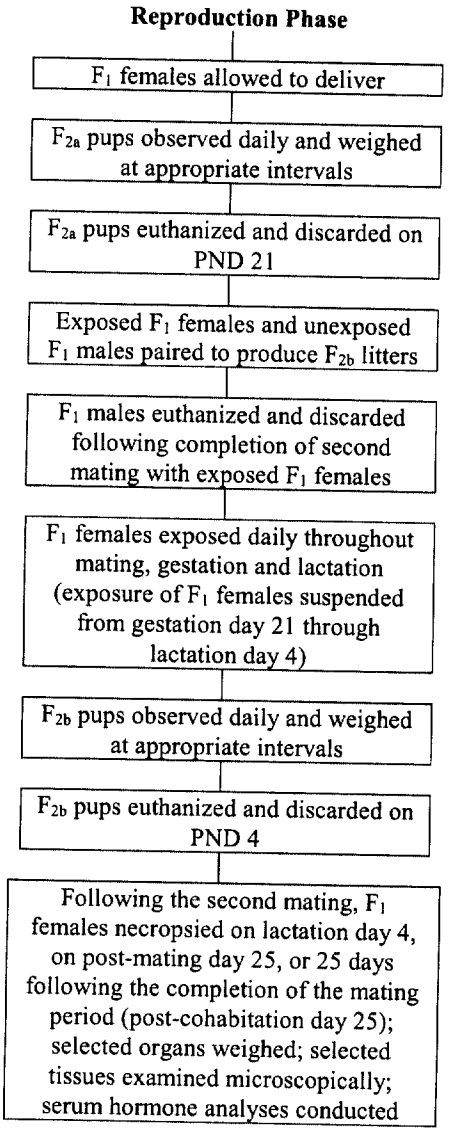
STUDY DESIGN (CONTINUED)



STUDY DESIGN (CONTINUED)



9. EXPERIMENTAL PROCEDURES

9.1. KEY STUDY DATES

Date(s)	Event(s)
November 13, 2001	Initiation of F_0 exposures
November 19 - December 1, 2001	Allotted F_0 breeding interval
December 4, 2001	F_0 males euthanized and discarded
December 15, 2001 - January 10, 2002	Necropsies of F_0 females
January 1 - 17, 2002	Unselected F_1 pups euthanized and discarded on PND 21 or 28
January 2, 2002	Initiation of F_1 exposures (first PND 22 for Groups 1, 2, 4 and 5)
January 24, 2002	Initiation of F_1 exposures (first PND 44 for Group 3)
March 27 - April 9, 2002	Allotted F_1 breeding interval: first mating
May 10 - 23, 2002	F_{2a} pups euthanized and discarded on PND 21
June 19 - July 2, 2002	Allotted F_1 breeding interval: second mating
July 3, 2002	F_1 males euthanized and discarded
July 14 - 29, 2002	Necropsies of F_1 females; F_{2b} pups euthanized and discarded on PND 4
November 19, 2002	Final test article purity determinations
April 26, 2003	Last F_1 histopathological examination

The following computer protocols were used for data collection during the study:

Computer Protocol	Type of Data Collected
WIL-51086F	F_0 maternal and F_1 litter data
WIL-51086D	F_1 maternal and F_2 litter data for first mating
WIL-51086E	F_1 maternal and F_2 litter data for second mating
WIL-51086S	F_0 female satellite animals (Groups 1 and 2) for pharmacokinetic evaluation on gestation day 20
WIL-51086G	F_1 selected weanlings from Group 2 for pharmacokinetic evaluation on PND 21

Computer Protocol	Type of Data Collected
WIL-51086H	F_1 weanlings from Group 5 for pharmacokinetic evaluation on PND 26 (animals discarded and not used)
WIL-51086K	F_1 selected weanlings from Group 5 for pharmacokinetic evaluation on PND 26
WIL-51086J	F_1 PND 21-28 unselected weanlings

Because of spacing constraints, the study title is presented as "An Inhalation Repro. Study of D_4 in Female Rats" on the report tables.

9.2. TEST AND CONTROL ARTICLES

9.2.1. TEST ARTICLE SYNTHESIS

The test article was synthesized by Dow Corning Corporation (2200 W. Salzburg Road, Midland, Michigan 48686-0994) in February, 1995. The methods used in the synthesis of the test article are summarized in the Material Documentation Management System document for the test article. A copy of this document is included in the study records maintained by the sponsor for this study.

9.2.2. TEST ARTICLE IDENTIFICATION

The test article, octamethylcyclotetrasiloxane (D_4), was received from Dow Corning Corporation, Auburn, Michigan, on September 21, 2001, as follows:

Identification	Quantity Received	Description
Dow Corning® 244 Fluid Lot # LL084732 Recertification Date: March 4, 2004 [WIL Log No. 5312A]	3 Drums Drum #1: 206.3 kg Drum #2: 202.6 kg Drum #3: 208.6 kg	Clear colorless liquid[a]

a = As described by WIL Formulations Laboratory personnel. The test article is described as colorless liquid in the protocol.

Retention and/or residual samples from each drum of the test article used in this study were analyzed for purity by the Analytical Chemistry Department at WIL Research

Laboratories, LLC. Details of the sample collection and their analyses are presented in Appendix A. The test article purity was determined to be at least 99.8%. The test article was stable when stored at room temperature. A retention sample of the test article was collected from drum no. 1 on October 22, 2001. The retention sample is stored in the Archives at WIL Research Laboratories, LLC, 1407 George Road, Ashland, Ohio 44805-9281. Following the completion of the in-life phase of study, all remaining test article was returned to the sponsor.

9.2.3. TEST ATMOSPHERE MONITORING

Exposure concentrations within each chamber were measured approximately every 30 minutes, yielding approximately 10 data points, during each daily exposure period by a validated gas chromatographic method. The GC was initially calibrated using a set of five standards prepared in triplicate; however, daily checks to confirm the GC calibration were conducted with a single standard. The standard each day was rotated so that a different standard was used daily to confirm GC calibration over the entire range. Chamber temperature, relative humidity, ventilation rate, and negative pressure within the chambers were monitored continuously and were recorded approximately every 30 minutes. Oxygen content within the chamber was measured during pre-study method development. Nominal chamber concentrations were determined daily for each chamber by weighing the amount of test article used during atmosphere generation, converting this mass to volume using standard gas laws, and dividing this test article volume by the total volume of air displaced through the chamber during the exposure. Total air volume was calculated by multiplying mean chamber ventilation rate (in standard liters per minute) by the exposure duration (in minutes). Test atmosphere homogeneity was validated during pre-study method development. The methodology and results of these analyses are presented in Appendix B.

9.2.4. EXPOSURE METHODS

Each group of animals was exposed in a 2.0-m^3 stainless steel and glass whole-body inhalation chamber. One chamber (Chamber 1) was dedicated for the filtered-air control

groups and the second chamber (Chamber 2) was dedicated for the test article-exposure groups. The chambers were operated under dynamic conditions at air flows of at least 12 to 15 air changes per hour.

The F_0 females were exposed to filtered air or to the test atmosphere for daily 6-hour exposures for a minimum of 7 consecutive days prior to mating. The F_1 females were exposed to filtered air or to the test atmosphere for daily 6-hour exposures (7 days a week) for a minimum of 70 consecutive days prior to mating. Exposure of the F_0 and F_1 females continued throughout mating and gestation through gestation day 20. Exposure of the F_0 females was re-initiated on lactation day 5 and continued through lactation day 20 of the second mating period. Exposure of the F_1 females was re-initiated on lactation day 5 following the first littering and continued during the second mating and gestation periods through gestation day 20. For F_1 females that had evidence of mating but did not deliver offspring following the first littering, exposures were re-initiated on post-mating day 26 and continued during the second mating and gestation periods through gestation day 20 of the second mating period. During lactation, the dams were removed from their litters during each daily 6-hour exposure period. The control groups were exposed to clean, filtered air under conditions identical to those used for the groups exposed to the test article. The rats were removed from their home cages in the animal room and transported to the inhalation chambers for the 6-hour exposure period. The animals were exposed to the test article or filtered air at approximately the same time each day. Following exposure, the animals were returned to their home cages. Instrumentation was set to maintain the temperature inside the exposure chamber between 20°C and 26°C and relative humidity between 30% and 70%. Exposure methods and conditions are detailed in Appendix B.

One chamber was dedicated to each control group during the F_0 (Groups 1 and 5) and F_1 (Groups 1 and 4) generations, as well as one chamber dedicated to each test article exposure group during the F_0 (Groups 2, 3 and 4) and F_1 (Groups 2, 3 and 5) generations. In order to minimize any potential variation occurring due to positioning within the

chamber, the cages were sequentially rotated around the available rack positions within the chamber on a daily basis throughout the study, in accordance with the standard operating procedures at WIL Research Laboratories, LLC.

The F_0 females were assigned to study groups as follows:

Group Number	Test Article	Exposure Level (ppm)	Number of F_0 Females: Reproduction Phase	Number of F_0 Females: Satellite Phase
1	Filtered Air	0	30	6
2	D_4	700	30	6
3	D_4	700	30	0
4	D_4	700	30	0
5	Filtered Air	0	30	0

A diagram of the exposure periods for each group is presented in Appendix C.

The F_1 females were assigned to study groups as follows:

Group Number	Test Article	Exposure Level (ppm)	Number of F_1 Females: Reproduction Phase	Number of F_1 Females: Satellite Phase
1	Filtered Air	0[a]	30	0
2	D_4	700[a]	30	0
3	D_4	700[b]	30	0
4	Filtered Air	0[a]	30	0
5	D_4	700[a]	30	5

[a] Exposures initiated on PND 22
[b] Exposures initiated on PND 44

A diagram of the exposure periods for each group is presented in Appendix C.

Group 1 (Filtered Air Control Group): The F_0 females in this group assigned to the reproduction phase (30 females/group) were exposed to filtered air daily beginning 7 days prior to mating and continuing throughout mating and gestation through gestation day 20.

Exposures were suspended from gestation day 21 through lactation day 4; exposures were re-initiated on lactation day 5 and continued through lactation day 20. Beginning on PND 22, the F_1 females were exposed to filtered air for a minimum of 70 days prior to the first mating period. Exposures continued throughout mating and gestation as described for the F_0 females. Following parturition, the F_1 females with evidence of mating were exposed to filtered air beginning on lactation day 5 and continuing throughout the remainder of lactation, following weaning of the F_{2a} pups and the second mating and gestation periods through gestation day 20 of the second mating period. This group served as the negative control group, against which results from all other groups were compared. For F_1 females with evidence of mating that did not deliver following the first littering, exposures were re-initiated on post-mating day 26 and continued during the second mating and gestation periods through gestation day 20 of the second mating period.

The F_0 females in this group assigned to the satellite phase (six females/group) were exposed to filtered air continually starting 7 days prior to mating and continuing throughout mating and gestation through gestation day 20.

Group 2 (Intra-Assay Control Group): This group assessed the reproducibility of the fertility data in comparison to the previous two-generation study[1]. Therefore, the exposure regimen for this group emulated that employed on the previous study except that the females were exposed for only 7 days instead of 70 days prior to mating. The F_0 females in this group assigned to the reproduction phase (30 females/group) were exposed continually starting 7 days prior to mating and throughout the mating, gestation and lactation periods as described for Group 1. The F_1 female generation was exposed to D_4 beginning on PND 22 and continuing throughout the two mating periods as described for Group 1.

The F_0 females in this group assigned to the satellite phase (six females/group) were exposed continually starting 7 days prior to mating and continuing throughout mating and gestation through gestation day 20.

Group 3 (6-Week Old F_1 Exposure Group): This group was included to investigate potential differences between starting the F_1 exposures at approximately six weeks of age versus three weeks of age. The F_0 females were exposed to D_4 as described for Group 2. The F_1 female weanlings were not exposed to D_4 or filtered air from weaning through PND 43. Direct exposure of the selected F_1 females to D_4 was initiated on PND 44 and continued throughout the two F_1 mating periods as described for Group 2.

Group 4 (*In Utero*/Lactation Exposure Group): This group was included to investigate whether the previously observed fertility effect was associated with indirect test article exposure of the F_1 animals *in utero* and during lactation. The F_0 females were exposed to D_4 as described for Group 2. Direct exposure of the F_1 females to D_4 did not occur. Beginning on PND 22, the F_1 females were exposed to filtered air prior to mating and continuing throughout two mating periods as described for Group 1.

Group 5 (3-Week Old F_1 Exposure Group): This group was included to investigate effects on fertility when F_1 exposures were initiated at 3 weeks of age and occurred in the absence of any maternal and potential *in utero* and nursing exposure to the test article. The F_0 females were exposed to filtered air as described for Group 1. Direct exposure of the selected F_1 females to D_4 began on PND 22 and continued throughout the two F_1 mating periods as described for Group 2.

An additional five F_1 females in this group, assigned to the satellite phase, were exposed for 5 consecutive days from PND 22 through PND 26.

9.3. F_0 ANIMAL RECEIPT AND ACCLIMATION

One hundred eighty female Crl:CD®(SD)IGS BR rats were received from Charles River Laboratories, Inc., Portage, Michigan, on November 1, 2001. The animals were 78 days old upon receipt. Animals were individually housed in clean, suspended, wire-mesh cages, suspended above cage-board, in an environmentally controlled room. The wire-mesh cages used to house the animals during the study were approximately 6 3/4" W x 9 5/8" D x 7 1/8" H or 10 3/16" W x 10 1/16" D x 7" H (depending on particular cage

style used). Each animal was examined by a qualified technician upon receipt and weighed the day following receipt. All animals were uniquely identified by a Monel® metal eartag displaying the animal number. The males used on this study were obtained from the stock colony at WIL Research Laboratories, LLC and were received from the same supplier as the females. During the acclimation period (12 days), individual body weights were recorded twice (following receipt and at randomization), and the animals were observed twice daily for mortality and moribundity.

9.4. F_0, F_1 AND F_2 ANIMAL HOUSING

Following the initial acclimation period (F_0) or PND 28 selection (F_1) and until pairing, all F_0 and F_1 parental test animals were individually housed in clean, wire-mesh cages suspended above cage-board, which was changed three times per week. Individual cage cards, which displayed the animal number, exposure group number, WIL study number, and exposure level were affixed to each cage. The animals were paired for mating in the home cage of the male. Following positive evidence of mating, the unexposed males were euthanized and discarded without examination, and the exposed females were transferred to plastic maternity cages (approximately 10 1/2" W x 19" D x 8" H) with ground corncob nesting material (Bed-O'Cobs®; The Andersons, Industrial Products Division, Maumee, Ohio). Periodic analyses of the nesting material for the presence of contaminants are performed by the manufacturer. The results of these analyses were reviewed by the study director, and it was determined that contaminants were not present in the nesting material at levels that would interfere with the objectives of this study. The dams were housed in these cages until weaning on lactation day 21. Following weaning of the F_1 litters, the F_0 maternal females were individually housed in suspended wire-mesh cages until the scheduled necropsy. The F_1 maternal females were housed individually following weaning of the F_{2a} litters and were then remated with the F_1 unexposed males and housed during gestation as described previously until necropsy. Beginning on PND 28, the F_1 rats were housed individually in suspended wire-mesh cages, except during the F_1 mating period. Maternal females for which there was no

evidence of mating were placed in plastic maternity cages with nesting material upon completion of a 14-day mating period. If these animals did not deliver after 25 days, they were returned to individual suspended wire-mesh cages. Animals were housed in accordance with the "Guide for the Care and Use of Laboratory Animals."[3] The animal facilities at WIL Research Laboratories, LLC, are accredited by the Association for Assessment and Accreditation of Laboratory Animal Care International (AAALAC International).

9.5. DIET, DRINKING WATER AND MAINTENANCE OF F_0 AND F_1 ANIMALS

The basal ration used in this study was PMI Nutrition International, Inc., Certified Rodent LabDiet® 5002, in meal form; the lot numbers used were recorded in the study records. The diet used at WIL Research Laboratories, LLC, was a certified feed with appropriate analyses performed and provided by the manufacturer. Municipal water supplying the facility is regularly sampled and analyzed for contaminants according to standard operating procedures. The results of these analyses were reviewed by the study director, and it was determined that contaminants were not present in animal feed or water at levels that would interfere with the objectives of this study. Feeders were changed and sanitized once per week. Reverse osmosis-purified drinking water, delivered by an automatic watering system, and the basal diet were provided *ad libitum* throughout the acclimation period and during the study, with the following exceptions. Food and water were withheld during each daily exposure period.

9.6. ENVIRONMENTAL CONDITIONS

Except during exposure, all animals were housed throughout the acclimation period and during the study in an environmentally controlled room. Instrumentation was set to maintain room temperature and humidity controls at daily averages of 71 ± 5°F (22 ± 3°C) and 50 ± 20% relative humidity. Prior to March 1, 2002, room temperature and relative humidity were recorded daily. During this time, the actual temperature ranged from 71.0°F to 76.3°F (21.7°C to 24.6°C) and humidity ranged from 30.7% to 52.2%. From March 1, 2002 through the end of the study, room temperature and relative humidity were

monitored using the Metasys® Network and were recorded approximately hourly. These data are summarized in Appendix D. Actual mean daily temperature in the nonexposure animal room ranged from 66.8°F to 74.9°F (19.3°C to 23.8°C) and mean daily relative humidity ranged from 35.5% to 59.8% during the study. Light timers were calibrated to provide a 12-hour light (6 a.m. to 6 p.m.)/12-hour dark photoperiod. Air handling units were set to provide approximately 10 fresh air changes per hour.

9.7. ASSIGNMENT OF F_0 ANIMALS TO TREATMENT GROUPS

At the conclusion of the acclimation period, all available F_0 animals were weighed and examined in detail for physical abnormalities. At the discretion of the study director, animals judged to be in good health and meeting acceptable body weight requirements were selected for use in the computerized randomization procedure, which ensures homogeneity of group means and variances for body weight. The weight of each animal was within ± 20% of the overall mean. At that time, the individual body weights and corresponding animal identification numbers were entered into the WIL Toxicology Data Management System (WTDMS™). A printout containing the animal numbers, corresponding body weights and individual group assignments was generated based on body weight stratification randomized in a block design. The animals were then arranged into groups according to the printout. The females were approximately 13 weeks old at the initiation of test article exposure. Female body weights ranged from 228 g to 292 g on the day of randomization (prior to study initiation). The individual randomization weights are not presented in this report but were placed in the study records.

9.8. DATA RETENTION

The sponsor has title to all documentation records, raw data, specimens or other work product generated during the performance of the study. All work product generated by WIL Research Laboratories, LLC, including raw paper data, magnetically encoded records and specimens, are retained in the Archives at WIL Research Laboratories, LLC, until notification from the sponsor regarding final disposition of the said work products. Pathology data used to generate the report by Dr. McConnell are retained at WIL

Research Laboratories, LLC. Pharmacokinetic data generated by Dow Corning Corporation will be archived by the sponsor.

The raw data, the retention and residual samples of the test article, pertinent electronic storage media, the original protocol, protocol amendments, deviations and the original final report are retained in the Archives at WIL Research Laboratories, LLC, 1407 George Road, Ashland, Ohio 44805-9281, in compliance with regulatory requirements.

10. PARAMETERS EVALUATED

10.1. F_0 AND F_1 OBSERVATIONS

10.1.1. CLINICAL OBSERVATIONS AND MORTALITY

The unexposed males were observed twice daily for moribundity and mortality. These observations are maintained in the raw data.

The females were observed twice daily for appearance, behavior, moribundity, and mortality. Detailed physical examinations were recorded weekly for all females throughout the study period. All observations were performed by the same trained technicians, whenever possible. Exposed females were also observed for clinical signs within approximately 1 hour after completion of exposure. All significant clinical findings were noted at the post-exposure observations. The examinations included, but were not limited to, evaluations for changes in the skin, fur, eyes, mucous membranes, respiratory, circulatory, and autonomic and central nervous system function, somatomotor activity, and behavior patterns. Special attention was paid to the degree of salivation and lacrimation, presence or absence of urination and defecation (including polyuria and diarrhea), pupil size, degree of palpebral closure, presence of convulsions, tremors or abnormal movements, presence of posture and gait abnormalities, and the presence of any unusual or abnormal behaviors and any repetitive actions (stereotypies). Females that were expected to deliver were also observed twice daily during the period of expected parturition and at parturition for dystocia (prolonged labor, delayed labor) or other difficulties at parturition.

10.1.2. BODY WEIGHTS

Individual body weights for the unexposed F_0 and F_1 males were recorded on a weekly basis until euthanasia and are maintained in the raw data.

Individual F_0 and F_1 female body weights were recorded on a weekly basis, beginning with the initiation of exposure and continuing until evidence of copulation was observed. Group mean body weights were calculated weekly. Individual and group mean body

weight changes were calculated for each weekly interval. Once evidence of mating was observed, individual female body weights were measured on gestation days 0, 7, 10, 14 and 20 and on lactation days 1, 4, 7, 14 and 21. Group mean body weights were calculated for each of these days. Individual and group mean body weight changes were calculated for each corresponding gestation or lactation interval and for gestation days 0-20 and lactation days 1-21. After weaning (lactation day 21), weekly body weights were recorded for the F_0 females until the scheduled necropsy. For the F_1 females, weekly body weights were recorded beginning after weaning of the F_{2a} litters on lactation day 21 and continuing until evidence of copulation was observed after the second pairing with the F_1 males. Once evidence of mating was observed, individual F_1 female body weights were measured on gestation days 0, 7, 10, 14 and 20 and on lactation days 1 and 4. Cumulative body weight changes presented in the tables include intervals from the start of exposure to the beginning of each breeding period (weeks 8-19 for the first breeding period and 8-31 for the second breeding period).

When body weights were unavailable for a given interval, the appropriate interval was footnoted as "NA" (Not Applicable) in the individual tables.

10.1.3. FOOD CONSUMPTION

Individual F_0 and F_1 female food consumption was measured weekly until pairing. Food intake was not recorded during the mating period. Once evidence of mating was observed, individual female food consumption was recorded on gestation days 0, 7, 10, 14 and 20 and on lactation days 1, 4, 7, 14 and 21. After weaning of the F_{2a} litters, food consumption for F_1 females was recorded weekly until the start of the second mating period with the F_1 males. Once evidence of mating was observed, individual food consumption was measured on gestation days 0, 7, 10, 14 and 20 and on lactation days 1 and 4. Food consumption was not measured for the unexposed males. Food consumption was calculated and reported as g/animal/day and g/kg/day for the corresponding body weight change intervals. Individual food efficiency (body weight

gained as a percentage of food consumed) was also calculated and reported for each weekly, gestation, and lactation interval. Calculations are as follows:

$$\text{g/animal/day} = \frac{\text{Total food consumed (g) per interval}}{\text{Number of days in interval}}$$

$$\text{g/kg/day} = \frac{\text{Total food consumed (g) per interval}}{\text{Mean body weight (kg) per interval*} \times \text{Number of days in interval}}$$

$$\text{* mean body weight per interval} = \frac{\text{(Body weight at beginning of interval + Body weight at end of interval)}}{2}$$

$$\text{Food efficiency (\%)} = \frac{\text{Total body weight gained (g) per interval}}{\text{Total food consumed (g) per interval}} \times 100$$

When food consumption could not be determined for an animal during a given interval (due to a weighing error, food spillage, obvious erroneous value, *etc.*), the appropriate interval was footnoted as "NA" (Not Applicable) on the individual tables.

10.2. F_0 AND F_1 REPRODUCTIVE PERFORMANCE

10.2.1. ESTROUS CYCLES

Vaginal lavages were prepared daily and the slides were evaluated to determine the stage of estrus for each F_0 female, beginning on the first day of exposure and continuing until evidence of mating was observed. For the F_1 selected females, slides were prepared daily beginning 21 days prior to each breeding period. An eyedropper or pipette containing 0.1-0.2 mL of deionized water was gently inserted into the vagina (no deeper than 0.5 cm). The deionized water was aspirated in and out of the vagina, the vaginal rinse was dropped onto a glass slide. Slides were stained with Giemsa stain and evaluated for the stage of estrus. For females with no evidence of copulation, lavaging was continued until termination of the mating period. The average cycle length was calculated for complete estrous cycles (*i.e.*, the total number of returns to metestrus [M] or diestrus [D] from estrus [E] or proestrus [P]). Estrous cycle length was determined by counting the number of days from the first M or D in a cycle to the first M or D in a subsequent cycle. The cycle during which evidence of mating was observed for a given animal was not

included in the mean individual estrous cycle length calculation. Vaginal lavages were also performed on the day of necropsy to determine the stage of estrus.

10.2.2. BREEDING PROCEDURES

At the conclusion of the acclimation period, the F_0 animals were randomly assigned to exposure groups as described in Section 9.7. The F_0 animals were paired on a 1:1 basis within each treatment group after a minimum of 7 consecutive days of test article exposure (females only). The first unexposed male stock rat was paired with the first female in that group, the second male was paired with the second female, *etc.*, until all animals were paired. A breeding record containing the male and female identification numbers and the date of cohabitation was prepared. Each female was housed in the home cage of the male. Positive evidence of mating was confirmed by the presence of a copulatory plug or the presence of sperm on a glass slide. Each mating pair was examined daily. The day when evidence of mating was identified was termed day 0 of gestation. Then the animals were separated and the female was housed individually in a plastic cage with nesting material. If no evidence of mating was detected after a period of 14 days, the female was placed in a plastic maternity cage with nesting material.

The F_0 generation was mated to allow production of one litter per dam (the F_1 litters). One day following the initiation of F_0 pairing (study week 1), female body weights ranged from 226 g to 296 g. The animals were approximately 13 weeks old. All animals were randomly selected for pairing.

Prior to weaning, the F_1 rats were randomly assigned to exposure groups as described in Section 10.4.7. The F_1 animals were paired on a 1:1 basis (avoiding sibling pairings) within each group following a minimum of 70 days of test article exposure. After a minimum of 30 days following weaning of the F_{2a} pups, each F_1 male was paired with the same F_1 female for a second mating period. Immediately prior to the initial F_1 pairing (study week 19), female body weights ranged from 228 g to 354 g. The animals were approximately 15 weeks old. Immediately prior to the second F_1 pairing (study week 31),

female body weights ranged from 264 g to 429 g. The animals were approximately 27 weeks old.

For the purpose of calculating pre-coital intervals, rats paired over a 12-hour dark cycle were considered to have been paired for 1 day.

Mating and fertility indices were calculated as follows:

$$\text{Female Mating Index (\%)} = \frac{\text{No. of Females with Evidence of Mating (or Confirmed Pregnancy)}}{\text{Total No. of Females Used for Mating}} \times 100$$

$$\text{Female Fertility Index (\%)}^{a} = \frac{\text{No. of Females with Confirmed Pregnancy}}{\text{Total No. of Females Used for Mating}} \times 100$$

$$\text{Female Fertility Index (\%)}^{b} = \frac{\text{No. of Females with Confirmed Pregnancy}}{\text{Total No. of Females with Evidence of Mating}} \times 100$$

[a] Environmental Protection Agency (EPA) method of calculation
[b] Organisation for Economic Cooperation and Development (OECD) method of calculation

10.3. F_0 AND F_1 PARTURITION

All females were allowed to deliver naturally and rear their young to weaning (PND 21), with the following exception. Following the second littering, the F_1 females remained with the litters until PND 4. During the period of expected parturition, the females were observed twice daily (approximately 8:00 a.m. and 2:00 p.m.) for initiation and completion of parturition and for signs of dystocia, prolonged labor, delayed labor, or any other difficulties during parturition. The day on which delivery initiated was designated lactation day 0. When parturition was completed, litters were sexed and examined for gross malformations, and the numbers of stillborn and live pups were recorded. Individual gestation lengths were calculated using the date delivery initiated.

10.4. F_1 AND F_2 LITTER DATA

10.4.1. LITTER VIABILITY AND DEATHS

Each litter was examined daily for survival, and all deaths were recorded. All pups were individually identified by application of tattoo markings on the digits on PND 0. A daily record of litter size was maintained. Intact offspring dying from PND 0 to 4 were necropsied using a fresh dissection technique described by Stuckhardt and Poppe.[4] Pups with external abnormalities which would warrant further skeletal examination were eviscerated and stained as described by Dawson[5] for subsequent skeletal evaluation. Findings were recorded as either developmental variations (alterations in anatomic structure that are considered to have no significant biological effect on animal health or body conformity, representing slight deviations from normal) or malformations (those anomalies that alter general body conformity, disrupt or interfere with body function, or may be incompatible with life). A detailed gross necropsy was performed on any pup dying after PND 4 and prior to weaning. The carcasses were discarded. Pups euthanized *in extremis* or due to the death of the dam were euthanized by an intraperitoneal injection of sodium pentobarbital and necropsied as described for the pups found dead.

10.4.2. LITTER REDUCTION

To reduce variability among the F_1 and F_{2a} litters, 8 pups per litter, 4 per sex when possible, were randomly selected on PND 4 using a computerized randomization procedure on WTDMS™. The remaining offspring were weighed, euthanized by an intraperitoneal injection of sodium pentobarbital and discarded on PND 4. Standardization of litter size was not performed on litters with fewer than eight pups or on the F_{2b} pups, because these pups were euthanized on PND 4.

10.4.3. CLINICAL OBSERVATIONS

Litters were examined daily for survival and any adverse changes in appearance or behavior. Each F_1 and F_{2a} pup received a detailed physical examination on PND 1, 4, 7, 14 and 21. Each F_{2b} pup received a detailed physical examination on PND 1 and 4. The observations included evaluations for changes in the appearance of the skin, fur, eyes,

mucous membranes, respiratory, circulatory, autonomic and central nervous system function, somatomotor activity, and behavior patterns. Any abnormalities in nesting and nursing behavior were recorded.

10.4.4. BODY WEIGHTS

Pups were individually weighed on PND 1, 4, 7, 14 and 21 (only on PND 1 and 4 for the F_{2b} litters). Mean pup weights were presented by sex for each litter and by exposure group.

10.4.5. SEX DETERMINATION

Pups were individually sexed on PND 1, 4, 7, 14 and 21 (only on PND 1 and 4 for the F_{2b} litters).

10.4.6. CALCULATION OF LITTER PARAMETERS

Litter parameters were defined as follows:

$$\text{Live Litter Size} = \frac{\text{Total Viable Pups Day 0}}{\text{No. Litters With Viable Pups Day 0}}$$

$$\text{Postnatal Survival Between Birth and PND 0 or PND 4 (Pre-Selection) (\% Per Litter)} = \frac{\Sigma\,(\text{Viable Pups Per Litter on PND 0 or PND 4/No. of Pups Born Per Litter})}{\text{No. of Litters Per Group}} \times 100$$

$$\text{Postnatal Survival for All Other Intervals (\% Per Litter)} = \frac{\Sigma\,(\text{Viable Pups Per Litter at End of Interval N/Viable Pups Per Litter at Start of Interval N})}{\text{No. of Litters Per Group}} \times 100$$

Where N = PND 0-1, 1-4 (Pre-Selection), 4 (Post-Selection)-7, 7-14, 14-21 or 4 (Post-Selection)-21

10.4.7. WEANING AND SELECTION

Each dam and litter remained housed together until weaning on lactation day 21, with the following exception. The F_{2b} litters were euthanized by an intraperitoneal injection of sodium pentobarbital on PND 4. Prior to weaning, a computerized randomization procedure on WTDMS™ was used to select 60 pups/sex/group (if possible) from the available F_1 pups. These pups were directly exposed to filtered air or the test article by

inhalation beginning on PND 22, with the following exception. The F_1 pups in Group 3 were exposed to D_4 beginning on PND 44. Of those pups selected prior to weaning, 30 pups/sex/group were selected on PND 28 to comprise the F_1 generation. A minimum of one male and one female from each litter were selected, when available. An additional male and/or female was selected from a litter, where necessary, to obtain 30 males and 30 females for each group. An additional five females were selected for Group 5 for exposure on PND 22-26 and subsequent pharmacokinetic analysis. Both the litters (from which the additional pups were selected) and the pups were selected using the same randomization procedure on WTDMS™. Pups selected for the F_1 generation also retained the F_0 dam number, followed by a hyphen "-" and the digit tattoo marking (*i.e.*, 99999-01). The selected F_1 animals were uniquely identified by a metal eartag. All other unselected F_1 pups were euthanized by intraperitoneal injection of sodium pentobarbital on PND 21 or 28 and discarded without examination.

10.5. SCHEDULED MACROSCOPIC EXAMINATIONS

10.5.1. F_0 AND F_1 GENERATIONS - ADULTS

All F_0 females were euthanized by carbon dioxide inhalation following a total loss of a litter (within 24 hours), following selection of the F_1 generation (lactation day 21), on post-mating day 25, or 25 days following the completion of the breeding period (post-cohabitation day 25). All surviving F_1 females were euthanized by carbon dioxide inhalation following a total loss of a litter (within 24 hours), on lactation day 4 (of the second mating), on post-mating day 25, or 25 days following completion of the second breeding period (post-cohabitation day 25). All F_0 and F_1 males were euthanized by carbon dioxide inhalation following their appropriate breeding periods and discarded without further examination. Moribund F_1 adults were euthanized *in extremis* by carbon dioxide inhalation. A complete necropsy was performed on all F_0 and F_1 females, and selective histopathologic examinations were conducted on all F_1 females as described in Section 10.7.4. Group 1 and 2 F_0 satellite females for pharmacokinetic analysis (Section 10.6.1.) were anesthetized by isoflurane inhalation and euthanized by

exsanguination on gestation day 20; the uteri of these females were examined to determine pregnancy status, and the carcasses were discarded without examination.

10.5.2. F_1 AND F_2 PUPS

Two F_1 male and two F_1 female weanlings per litter were selected on PND 21. Of these weanlings, 30 F_1 pups/sex/group were randomly selected for the F_1 parental generation. The additional F_1 pups were retained as potential replacement animals, and were euthanized by intraperitoneal injection of sodium pentobarbital and discarded without examination on PND 28. All non-selected F_1 weanlings and all F_{2a} weanlings were euthanized by intraperitoneal injection of sodium pentobarbital and discarded without examination on PND 21. Pups from the F_{2b} litters were euthanized by an intraperitoneal injection of sodium pentobarbital and discarded without examination on PND 4. Group 2 F_1 weanlings and Group 5 F_1 weanlings for pharmacokinetic analysis were anesthetized by isoflurane inhalation and euthanized by exsanguination on PND 21 and 26, respectively; the carcasses were discarded without examination.

10.6. PHARMACOKINETIC ANALYSIS

All whole livers and plasma and fat samples collected from Group 1 and Group 2 satellite F_0 females and their fetuses on gestation day 20 (Sections 10.6.1 and 10.6.2), Group 2 F_1 weanlings on PND 21 and Group 5 F_1 females on PND 26 (following 5 days of exposure) were shipped on dry ice to the sponsor for analysis of D_4. The samples were analyzed by a validated GC-MS method entitled "Procedure for Determination of D_4 in Biological Matrices." Clinical observations, reproductive performance, body weights, food consumption and pregnancy statuses collected for the Group 1 and Group 2 satellite F_0 females during the in-life phase are presented in Appendix E.

The results from analyses of these samples were reported in a contributing scientist report provided by the sponsor and are presented in Appendix F.

10.6.1. GROUP 1 AND GROUP 2 SATELLITE F_0 FEMALES

Approximately 5 minutes following the completion of exposure on gestation day 20, the Group 1 and Group 2 satellite F_0 females were anesthetized by isoflurane inhalation and euthanized by exsanguination from the vena cava or cardiac puncture, with the following exception. Because female no. 80217 in the control group had an extended pre-coital interval, this female was euthanized and discarded without examination. The blood was collected into tubes containing heparin as the anticoagulant. The blood samples were inverted several times and rocked back and forth for approximately 10 minutes. The samples were then placed on wet ice for approximately 10 minutes until centrifugation to avoid precipitation of D_4. Plasma was isolated by centrifugation at approximately 2000 x g for 10 minutes at ambient temperature. Two aliquots (approximately 200 µL each) of plasma from each sample were transferred into pre-weighed 4-mL glass vials and placed on wet ice until all samples were collected. After all samples were collected on a given day, the samples were placed at approximately -70°C within 1 hour of collection. In addition, whole livers and approximately 0.5 g of perineal fat were collected from each animal and placed into pre-weighed 4-oz glass jars and pre-weighed polypropylene tubes, respectively. The jars and tubes were placed on wet ice until all samples were collected. After all the samples were collected on a given day, the samples were placed at approximately -70°C within 1 hour of collection.

10.6.2. GROUP 1 AND GROUP 2 SATELLITE F_1 FETUSES

Following collection of the F_0 maternal tissues from Group 1 and Group 2 satellite F_0 females, blood samples from an umbilical vein, the whole livers and scapular fat samples were collected from all fetuses from each dam. The samples were pooled within each litter. The blood samples were collected using capillary tubes containing heparin. Plasma was isolated, and samples (plasma, liver and fat) were stored as described for the Group 1 and Group 2 satellite F_0 females. All fetal carcasses were discarded following sample collection.

10.6.3. F_1 PUPS

Five Group 2 F_1 weanlings were anesthetized by isoflurane inhalation and euthanized by exsanguination on PND 21. Five Group 5 females (exposed to D_4 on PND 22-26) were anesthetized by isoflurane inhalation and euthanized by exsanguination on PND 26, approximately 5 minutes following test article exposure. Whole livers and plasma and fat samples were collected and processed as described for Group 1 and Group 2 satellite F_0 females. The carcasses were discarded following sample collection.

10.7. PATHOLOGY

10.7.1. MACROSCOPIC EXAMINATION

A complete necropsy was conducted on all parental animals (F_0 and F_1) dying spontaneously, euthanized *in extremis* or surviving to the scheduled euthanasia. All surviving F_0 and F_1 females were euthanized by carbon dioxide inhalation. F_0 and F_1 males were euthanized and discarded without examination. The necropsy of the F_0 and F_1 females included examination of the external surface, all orifices, the cranial cavity, the external surfaces of the brain and spinal cord, and the thoracic, abdominal and pelvic cavities including viscera. At the time of necropsy, the following F_0 and F_1 maternal tissues and organs were collected and placed in 10% neutral-buffered formalin:

Mammary tissue	Uterus
Ovary	Vagina
Pituitary	Gross lesions

10.7.2. ORGAN WEIGHTS

The following organs from all F_0 and F_1 females euthanized at scheduled termination were weighed:

Ovary	Uterus (with oviducts and cervix)
Pituitary	

Absolute weights and organ to final body weight ratios were reported.

10.7.3. HORMONE ANALYSIS

Blood was collected at the terminal necropsy of all F_1 females from the vena cava, and serum was prepared for hormone analysis. Hormone analysis methods, procedures and references are presented in Appendix G. Serum obtained from the F_1 females was analyzed for the following:

Estradiol
Progesterone
Prolactin

10.7.4. HISTOLOGICAL PROCEDURES AND MICROSCOPIC EXAMINATION

Microscopic evaluations were performed on the following tissues for all F_1 maternal animals:

Mammary tissue
Ovary
Pituitary
Uterus
Vagina
Gross lesions

The following procedure was used for the preparation of all tissues. The pituitary glands from both the F_0 and F_1 females remained in 10% neutral-buffered formalin for only 24 hours. After fixation, specified tissues were trimmed as described by Thompson.[6] Trimmed specimens were placed in labeled and numbered cassettes. The fixed tissue samples were processed into paraffin blocks. The labeled paraffin blocks of the tissues for the F_1 females were sectioned at 5-8 microns, and the paraffin ribbons of the sectioned tissue were placed on clean glass microscopic slides labeled with the study, animal, group, and cassette numbers. Upon completion of staining with hematoxylin and eosin using established methods,[7] coverslips were placed on the slides. The paraffin blocks containing the pituitary glands from the F_0 females were not sectioned.

In addition, immunohistochemical staining for determination of prolactin and follicle stimulating hormone was done on sections of the pituitary gland from the F_1 females. Following formalin fixation, the pituitaries were processed immediately and paraffin

embedded. The tissues were then deparaffinized and hydrated with water. The slides were unmasked by placement into working pepsin solution for 10 minutes at 37°C ± 2°C and rinsed twice with reverse-osmosis water. Hydrogen peroxide was added for 5 minutes ± 30 seconds and then rinsed with Automation buffer. Approximately five drops of primary antibody, Link (Biotinylated anti-rabbit and anti-mouse immunoglobins), Streptavidin Peroxidase and DAB substrate-chromogen were added per slide and incubated for 10 ± 1 minutes; the slides were rinsed with Automation buffer prior to addition of each reagent. The sections were washed with reverse-osmosis purified water then counterstained with hemotoxylin for 10-45 seconds. The sections were then rinsed quickly in tap water, followed by 70% ethyl alcohol, 95% ethyl alcohol and 100% ethyl alcohol. The sections were soaked in 100% ethyl alcohol for 3-10 minutes followed by an additional 3- to 10-minute soak in xylene. The slides remained in the xylene until coverslipped. Paraffin blocks and slides of the pituitary glands from all F_1 females were shipped to Dow Corning Corporation, Midland, Michigan. Because of inconsistent staining, assessment of the stained slides was not performed.

Microscopic examinations of the pituitary glands, mammary tissues, ovaries, uteri and vaginas were conducted by Robert F. McConnell, D.V.M., D.A.C.V.P., P.A., Consulting Pathology Services, Penn Valley, California. At the request of the sponsor, the examinations were performed in a blinded manner. The results of the examinations performed by Robert F. McConnell, D.V.M., D.A.C.V.P., P.A., are presented in Appendix H.

10.8. STATISTICAL METHODS

All statistical tests were performed using appropriate computing devices or programs. Analyses were conducted using two-tailed tests (except as noted otherwise) for minimum significance levels of 1% and 5%, comparing each test article-treated group to the filtered air control group. Each mean was presented with the standard deviation (S.D.) and the number of animals (N) used to calculate the mean. Due to the different rounding conventions inherent in the types of software used, the means and standard deviations on

the summary and individual tables may differ by ±1 in the last significant figure. Statistical analyses were not conducted if the number of animals was two or less. Data obtained from nongravid animals were excluded from statistical analyses following the mating period. Statistical analyses were not performed when weekly food or body weight data for one or more animals were not available because the animals remained in the lactation phase. The litter was used as the experimental unit.

Parental mating and fertility indices were analyzed using the Chi-square test with Yates' correction factor.[8] Mean maternal (weekly, gestation and lactation) and offspring body weight data, parental food consumption and food efficiency data, estrous cycle data, pre-coital intervals, gestation lengths, implantation sites, live litter sizes, unaccounted sites, numbers of pups born, absolute and relative organ weights and serum hormone levels were subjected to a parametric one-way analysis of variance (ANOVA)[9] to determine intergroup differences. If the ANOVA revealed statistical significance ($p<0.05$), Dunnett's test[10] was used to compare the test article-treated groups to the filtered air control group. Mean litter proportions (percent per litter) of postnatal pup survival and pup sexes at birth (percentage of males per litter) were subjected to the Kruskal-Wallis nonparametric ANOVA test[11] to determine intergroup differences. If the ANOVA revealed statistical significance ($p<0.05$), the Mann-Whitney U-test[11] was used to compare the test article-treated groups to the filtered air control group.

11. RESULTS AND DISCUSSION

11.1. F_0 GENERATION

11.1.1. CHAMBER CONCENTRATIONS

Summary Data: Appendix B

The F_0 females were exposed to target test article concentrations of 0 or 700 ppm. The actual mean measured exposure concentration was 704 ppm.

11.1.2. CLINICAL OBSERVATIONS AND SURVIVAL

Summary Data: Tables 1, 2, 3

Individual Data: Tables 107, 108, 109

All F_0 females survived until scheduled euthanasia. No exposure-related clinical signs were noted at the daily examinations or 1 hour following exposure. The clinical observations that were reported were unremarkable and either occurred infrequently or with similar frequency in the control group.

11.1.3. REPRODUCTIVE PERFORMANCE

Summary Data: Tables 4, 5

Individual Data: Tables 110, 111

Historical Control Data: Appendix I

F_0 reproductive performance was not adversely affected by exposure to the test article. The mean numbers of days between pairing and coitus (2.8, 2.0, 2.5, 2.3 and 2.8 for the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively) were comparable across all exposure groups and similar to the WIL historical control data (mean of 2.7 days and a range of 2.0 to 3.5 days).

Female mating indices were 100%, 96.7%, 100%, 100% and 100% for the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; none of the differences from the control group were statistically significant. One female in the 700/700-D22 ppm group had no evidence of mating, did not deliver and was not gravid.

Another female in the 700/0 ppm group had no evidence of mating but delivered. One, three and one females in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, had total litter losses. Female fertility indices were 96.7%, 93.3%, 93.3%, 96.7% and 86.7% when calculated by the EPA method and 96.7%, 96.6%, 93.3%, 100% and 86.7% when calculated by the OECD method (refer to Section 10.2.2. for a description of the EPA and OECD calculation methods) for the 0/0, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; none of the differences from the control group were statistically significant. One and four females in the 700/700-D22 and 700/0 ppm groups, respectively, had evidence of mating and did not deliver, but were found to be gravid at the *postmortem* examination. The presence of gravid females that failed to deliver is consistent with the previously conducted two-generation study (WIL-51036[1]). In that study, three F_0 females in the 700 ppm group also had evidence of mating, did not deliver but were found to be gravid at the *postmortem* examinations. Rarely do gravid females fail to deliver offspring. In the two F_0 groups exposed to filtered air, all 55 gravid females delivered offspring compared to only 52 of 57 gravid females in both the 700/700-D22 and 700/0 ppm groups. Therefore, the failure of five gravid females to deliver in these two groups exposed to 700 ppm D_4 was considered to be exposure-related. The lack of gravid females that failed to deliver in the 700/700-D44 group demonstrated that this finding occurs at a low frequency following exposure to 700 ppm of D_4.

Based on assessment of the limited data available, mean estrous cycle length was unaffected by exposure to the test article. Mean estrous cycle lengths were 4.4, 4.2, 4.1, 4.3, and 4.3 days for the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; none of the differences from the control group were statistically significant. However, mean estrous cycle lengths could not be determined for 16, 25, 19, 19, and 15 females in the same respective groups because no complete estrous cycles occurred for those females. The pre-breeding period for this study covered only 1 week and was thus too short to be able to detect a full cycle for these females.

11.1.4. BODY WEIGHTS

11.1.4.1. WEEKLY

Summary Data: Tables 6, 7, Figure 1

Individual Data: Tables 112, 113

Test article-related (statistically significant at $p<0.05$ or $p<0.01$) reduced mean weekly body weight gains and/or mean body weight losses were noted in the F_0 female groups that were exposed to the test article at 700 ppm (700/700-D22 ppm, 700/700-D44 ppm, and 700/0 ppm groups) during the pre-breeding period (week 0-1). As a result, mean weekly body weights in all 700 ppm groups (Groups 2, 3, and 4) were slightly lower than the control group during study week 1. The differences in the 700/700-D44 and 700/0 ppm groups were statistically significant ($p<0.05$ or $p<0.01$) when compared to the control group. Mean body weights and body weight gains in the 0/700 ppm group were comparable to the control group during the pre-breeding period (week 0-1).

11.1.4.2. GESTATION

Summary Data: Tables 8, 9, Figure 2

Individual Data: Tables 114, 115

Mean body weight gains were statistically significantly ($p<0.05$ or $p<0.01$) reduced for all F_0 female groups that were exposed to the test article at 700 ppm (700/700-D22 ppm, 700/700-D44 ppm, and 700/0 ppm groups) during gestation days 0-7. However, because the weight gain in these groups were comparable to the 0/700 ppm group (F_0 exposure to filtered air), these reductions in body weight gain were not considered to be test article-related. Mean body weight gains in these groups were similar to the control group during gestation days 7-10 and 10-14, but again were reduced (statistically significant at $p<0.01$) by the end of the gestation period (gestation days 14-20) and when the entire gestation period (gestation days 0-20) was evaluated. The mean body weight gain reduction late in gestation was considered to be reflective of the subsequently observed reduced number of pups born in the 700 ppm groups. Mean body weights in the 700 ppm

groups (Groups 2, 3 and 4) were statistically significantly ($p<0.05$ or $p<0.01$) reduced on gestation days 7, 10, 14, and 20. The most marked reductions in mean body weight were observed on gestation day 20, when mean body weights in these groups were 8-10% lower than the control group mean. Mean body weight and body weight gain in the 0/700 ppm group were similar to the control group values; any differences noted (statistically significant or otherwise) were considered transient.

11.1.4.3. LACTATION

Summary Data: Tables 10, 11, Figure 3

Individual Data: Tables 116, 117

Mean body weight gains were unaffected by exposure to the test article and were comparable across all groups during the lactation period. The only statistically significant difference noted was an increase in the 700/0 ppm group during lactation days 14-21. However, mean body weights were lower (generally statistically significant at $p<0.05$ or $p<0.01$) than the control group values for all F_0 females exposed to the test article at 700 ppm (Groups 2, 3 and 4) on lactation days 1, 4, 7 and/or 14, as a result of the decreased mean gestation body weights. Mean body weights in the 700/700-D22, 700/700-D44 and 700/0 ppm groups were similar to the control group on lactation day 21; the differences were not statistically significant. Mean lactation body weights and body weight gains in the 0/700 ppm group were comparable to the control group values.

11.1.5. FOOD CONSUMPTION

11.1.5.1. WEEKLY

Summary Data: Tables 12, 13, 14

Individual Data: Tables 118, 119, 120

Weekly food consumption (evaluated as g/animal/day and g/kg/day) was reduced in the 700/700-D22, 700/700-D44 and 700/0 ppm groups during week 0-1, consistent with the reduced mean body weight gains observed in these groups during this interval. The differences from the control group were statistically significant ($p<0.01$) and were

attributed to test article exposure. These reductions in food consumption, combined with the effects on body weight parameters during this period, resulted in statistically significantly ($p<0.05$ or $p<0.01$) lower food efficiency in these groups during the pre-breeding period.

11.1.5.2. GESTATION

Summary Data: Tables 15, 16, 17

Individual Data: Tables 121, 122, 123

Food consumption (evaluated as g/animal/day and g/kg/day) in the 700/700-D22, 700/700-D44 and 700/0 ppm groups was decreased (statistically significant at $p<0.01$) when compared to the control group during gestation days 0-7; the decreases were considered exposure-related. Food consumption (g/animal/day and g/kg/day) remained decreased (often statistically significant at $p<0.05$ or $p<0.01$) in the 700/700-D22 group (gestation days 7-10) and in the 700/700-D44 group (gestation days 7-10 and 10-14); the 700/0 ppm group values were similar to the control group during these intervals. Food consumption in the 700 ppm groups was generally similar to that in the control group during gestation days 14-20. Food consumption (g/animal/day and g/kg/day) in the 700/0 ppm group was reduced (statistically significant at $p<0.01$ when evaluated on a g/animal/day basis) relative to that in the control group for gestation days 0-20.

Mean food efficiency in the 700/700-D22, 700/700-D44 and 700/0 ppm groups was similar to the control group values during gestation days 0-7, 7-10 and 10-14; none of the differences were statistically significant. As a result of the mean body weight gain reductions late in gestation that were discussed previously, food efficiency was decreased for all 700 ppm-exposed groups over the entire gestation period (days 0-20 of gestation) due almost entirely to decreased food efficiency that was observed during gestation days 14-20. The differences from the control group were statistically significant ($p<0.05$ or $p<0.01$).

Food consumption (evaluated as g/animal/day and g/kg/day) and food efficiency in the 0/700 ppm group were similar to the control group. The only difference noted was a statistically significant ($p<0.05$) decrease on gestation days 0-7, but was considered to be transient.

11.1.5.3. LACTATION

Summary Data: Tables 18, 19, 20

Individual Data: Tables 124, 125, 126

Food consumption (evaluated as g/animal/day and g/kg/day) and food efficiency during lactation in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups were similar to the control group values. Occasional statistically significant increases were noted; however, none were toxicologically relevant because they were minimal in magnitude and/or transient.

11.1.6. GESTATION LENGTH AND PARTURITION

Summary Data: Table 21

Individual Data: Table 127

Historical Control Data: Appendix I

There were no exposure-related changes in mean gestation length for F_0 females exposed to the test article at 700 ppm (Groups 2, 3 and 4). For the 700/700-D44 and 700/0 ppm groups, the mean values were statistically significantly ($p<0.05$ or $p<0.01$) increased relative to the control group mean; however, these differences were not considered to be toxicologically relevant because the actual differences were minimal. Mean gestation lengths were 21.8, 22.1, 22.4, 22.3 and 21.8 days in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. The WIL historical control group mean is 21.8 days and ranges from 21.6 to 22.3 days. Current study data are all within or just slightly in excess of these historical control data and thus, were not considered to by indicative of an exposure-related effect. No signs of dystocia were noted in any exposure group. However, one and four females in the 700/700-D22 and

700/0 ppm groups, respectively, had evidence of mating, did not deliver but were found to be gravid at the *postmortem* examination. The lack of gravid females that failed to deliver in the 700/700-D44 group indicates that this finding occurs at a low frequency following exposure to 700 ppm D_4.

11.1.7. F_0 PATHOLOGY

11.1.7.1. MACROSCOPIC EXAMINATION

Summary Data: Tables 22, 23, 24, 25, 26

Individual Data: Tables 128, 129, 130, 131, 132

All F_0 females survived until scheduled necropsy (including females sent to necropsy on post-cohabitation day 25, females sent to necropsy on post-mating day 25, females with total litter loss, and females that delivered litters and survived to scheduled necropsy). No exposure-related internal findings were noted. Findings in the exposed groups were unremarkable and either occurred infrequently or with similar frequency in the control group.

Test article-related reductions were observed in the mean numbers of implantation sites for F_0 females exposed to the test article at 700 ppm (Groups 2, 3 and 4). The means for these groups were up to 31% lower than the control group mean, and the differences were statistically significant ($p<0.01$). The mean numbers of pups born were subsequently reduced ($p<0.01$) for all of these groups. The mean numbers of implantation sites and pups born in the 0/700 ppm group were similar to the control group. The mean numbers of unaccounted sites were comparable between the control and test article-exposed groups.

11.1.7.2. ORGAN WEIGHTS

Summary Data: Tables 27, 28, 29, 30, 31, 32, 33, 34

Individual Data: Tables 133, 134, 135, 136, 137, 138, 139, 140

There were no exposure-related effects on F_0 female organ weights. Mean absolute and relative (to final body weight) uterine, ovarian, and pituitary weights were comparable across all groups on study; no statistically significant differences were noted.

11.1.8. F_1 LITTER DATA

11.1.8.1. PND 0 LITTER DATA AND POSTNATAL SURVIVAL

Summary Data: Tables 35, 36

Individual Data: Tables 141, 142

Historical Control Data: Appendix I

Test article-related reductions were observed in the mean numbers of F_1 pups born and the subsequent mean live litter sizes on PND 0 for all 700 ppm-exposed groups; means for these parameters were reduced up to 37% in the exposed groups, and all reductions were statistically significant ($p<0.01$) compared to the control group values. The mean number of pups born in the 700/700-D22, 700/700-D44 and 700/0 ppm groups were 10.4, 9.5 and 10.1 pups per dam, respectively, compared to 14.8 pups per dam in the control group and 14.2 (range 12.0-16.3) pups per dam in the WIL historical control data. The reduced numbers of pups born and live litter size in the groups exposed to 700 ppm D_4 were consistent with the results of the previously conducted two-generation study (WIL-51036[1]) in which similar reductions were observed following exposure of F_0 females to 700 ppm D_4. The mean numbers of pups born and mean live litter sizes in the 0/700 ppm group were similar to the control group values. The percentage of males per litter at birth was unaffected by test article exposure in all groups.

Pup survival (percent per litter) was not affected by parental exposure in any of the 700 ppm groups from birth to PND 0, PND 0-1, PND 1-4, PND 4-7, PND 7-14, PND 14-21, birth to PND 4 and PND 4-21. No statistically significant differences

between the control and exposed groups were noted. One, three and one females in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, had total litter losses by lactation day 18.

11.1.8.2. GENERAL PHYSICAL CONDITION AND MORTALITIES

Summary Data: Tables 37, 38, 39, 40

Individual Data: Tables 143, 144, 145, 146

F_1 pups that were found dead or euthanized *in extremis* prior to weaning numbered 21, 22, 26, 5 and 12 in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. In these same respective groups, 6, 3, 10, 0 and 11 pups were missing and presumed to have been cannibalized. The general physical condition of F_1 pups during the lactation period was similar across all groups on study.

F_1 weanlings found dead or euthanized *in extremis* between PND 21 and 28 numbered 5, 10, 16, 9 and 5 in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. The general physical condition of the F_1 weanlings during PND 21-28 was similar across all groups on study.

11.1.8.3. OFFSPRING BODY WEIGHTS

Summary Data: Tables 41, 42

Individual Data: Tables 147, 148

Historical Control Data: Appendix I

Mean offspring body weight gains were increased during PND 1-4 in all 700 ppm groups; these increases were often statistically significant ($p<0.01$). Mean F_1 offspring body weights (males and females) were increased in the 700 ppm groups (Groups 2, 3 and 4) relative to the control group values on PND 1, 4 and 7; these increases were generally statistically significant ($p<0.05$ or $p<0.01$) and were considered related to the reduced mean live litter sizes observed in these groups. Mean offspring body weights in the 700 ppm groups were unaffected by test article exposure on PND 14 and 21.

Mean offspring body weights and body weight gains in the 0/700 ppm group were similar to the control group during the pre-weaning period. Because the 0/700 ppm group F_0 females were not exposed to D_4, any differences from the control (0/0 ppm) group were due to biological variation.

11.1.8.4. NECROPSIES OF PUPS FOUND DEAD OR EUTHANIZED *IN EXTREMIS*

Summary Data: Table 43

Individual Data: Table 149

No internal findings that could be attributed to maternal exposure to the test article were noted at the necropsies of F_1 pups that were found dead or euthanized *in extremis* prior to weaning. One control group pup had thick, red material in the cranial region and dark red discoloration of the brain. Aside from the presence or absence of milk in the stomach, no other internal findings were noted at the necropsies of pups found dead or euthanized *in extremis* prior to weaning.

11.2. PHARMACOKINETIC ANALYSIS

Pharmacokinetic Phase In-Life Data: Appendix E

Pharmacokinetic Report: Appendix F

The mean concentrations of D_4 in the liver, plasma and fat samples of F_0 satellite females in the control and 700 ppm groups and F_1 satellite fetuses and weanlings are summarized in the following table.

Group ID	Exposure Description	Plasma D_4 Concentration (µg/g ± Std. dev.)	Liver D_4 Concentration (µg/g ± Std. Dev.)	Fat D_4 Concentration (µg/g ± Std. dev.)
Group 1 F_0 Satellite Dams	Not Exposed	0.01 ± 0.00	BLQ	0.02 ± 0.00
Group 1 Fetuses	Not Exposed	0.04 ± 0.01	BLQ	0.02 ± 0.01
Group 2 F_0 Satellite Dams	Directly exposed 7 days prior to mating to GD 20	21.31 ± 5.45	120.91 ± 11.18	1566.32 ± 409.21
Group 2 Fetuses	Indirectly exposed *in utero* until GD 20	7.95 ± 2.31	37.04 ± 5.55	80.29 ± 27.33
Group 2 PND 21 F_1 females	Indirectly exposed *in utero* and through lactation until PND 21	0.20 ± 0.20	0.50 ± 0.34	21.67 ± 12.02
Group 5 PND 26 F_1 females	Directly exposed from PND 22 until PND 26, never indirectly exposed	4.48 ± 0.95	78.69 ± 9.83	333.90 ± 88.33

11.3. F_1 GENERATION

11.3.1. CHAMBER CONCENTRATIONS

Summary Data: Appendix B

The F_1 females were exposed to target test article concentrations of 0 or 700 ppm. The actual mean measured exposure concentration was 706 ppm.

11.3.2. CLINICAL OBSERVATIONS AND SURVIVAL

Summary Data: Tables 44, 45, 46

Individual Data: Tables 150, 151, 152

In the 700/700-D22, 700/700-D44 and 0/700 ppm groups, 1/30, 4/30 and 1/30 F_1 females, respectively, were found dead or euthanized *in extremis* between weeks 22 and 34; these mortalities were considered related to exposure because no deaths were observed in the two groups of F_1 females that were exposed to filtered air. In addition, all of the deaths and moribundity noted for these animals occurred around the time of expected parturition or shortly after parturition. Female no. 80286-08 in the 700/700-D22 ppm group was euthanized *in extremis* on gestation day 29 following the first breeding period. This

animal had brown vaginal discharge on the day of euthanasia and had two fetuses that were retained in the cervix. Four females in the 700/700-D44 group were found dead or euthanized *in extremis* and included the following. Female no. 80257-03 died on gestation day 22 following the first breeding period; no clinical findings were noted for this female. Female no. 80186-05 was euthanized *in extremis* on lactation day 5 following the first breeding period; on the day of euthanasia, this female was dehydrated, hypoactive and had hair loss on various body surfaces. Female no. 80245-09 was euthanized *in extremis* on lactation day 0 following the first breeding period; on the day of euthanasia, this female was prostrate and pale in color and had labored respiration and a body that was cool to the touch. Female no. 80189-04 died on lactation day 0 following the second breeding period; on the day of death, this female was lethargic and pale in color, and had labored respiration and a body that was cool to the touch. In the 0/700 ppm group, female no. 80124-06 died on gestation day 23 following the second breeding period; on the day prior to death, this female was hypoactive and had eyes that were pale in color. All other F_1 parental animals survived to the scheduled necropsy.

No other significant clinical signs were noted at any test article concentration. Other clinical findings observed in the exposed groups occurred infrequently and/or with similar frequency in the control group.

11.3.3. REPRODUCTIVE PERFORMANCE

11.3.3.1. FIRST MATING

Summary Data: Tables 47, 48

Individual Data: Tables 153, 154

Historical Control Data: Appendix I

The F_1 females were between 97 and 107 days old at the initiation of the first breeding period. For the first F_1 pairing, mean numbers of days between pairing and coitus (2.6, 2.9, 2.8, 3.7 and 3.2 days in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively) were comparable across all groups on study and were also

comparable to WIL historical control data for this endpoint (mean of 2.7 days and a range of 2.0 to 3.5 days).

Female mating indices were determined to be 93.3%, 100%, 93.3%, 100% and 93.3% in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; none of the differences from the control group were statistically significant. Three, two and two females in the control, 700/700-D44 and 0/700 ppm groups, respectively, had no evidence of mating, and two of these females in each group did not deliver a litter; one control group female had no evidence of mating when examined during the breeding period for either the presence of sperm in a vaginal smear or a copulatory plug, but delivered a litter. Female fertility indices were 86.7%, 76.7%, 83.3%, 96.7% and 80.0%, when calculated using the EPA method and 92.9%, 76.7%, 89.3%, 96.7% and 85.7%, when calculated using the OECD method (refer to Section 10.2.2. for a description of the EPA and OECD calculation methods) in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; none of the differences from the control group were statistically significant. Although, the differences in the fertility rates were not statistically significant, the reduced fertility (primarily when using the OECD method of calculation) in the 700/700-D22 ppm group was considered to be test article-related. The lower fertility rate in the 700/700-D22 group was the result of seven females that had evidence of mating that were determined to be nongravid compared to only two females in the control group. The inability of females with evidence of mating to deliver offspring in the 700/700-D22 group was even more pronounced in the second mating period (see Section 11.3.3.2.). The lower fertility rate in the 700/700-D22 ppm group compared to the other two groups of F_1 females exposed to D_4 was attributed to the fact that only the females in the 700/700-D22 group were exposed indirectly to D_4 *in utero* and during the pre-weaning period and directly to 700 ppm D_4 beginning on PND 22. This current study replicates the conditions observed in the previous two-generation study (WIL-51036[1]) where F_1 fertility was decreased. However, unlike the previous study, no reduction in mating indices was observed in the groups exposed to D_4.

Individual variation in the estrous cycles occurred in all study groups. Mean estrous cycle lengths were 4.4, 5.2, 4.4, 4.8, and 5.6 days in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; the differences from the control group were not statistically significant. The means for the 700/700-D22 and 0/700 ppm groups exceeded the maximum mean value reported in the WIL historical control database (mean of 4.3 days, ranging from 4.1 to 5.1 days). Therefore, these increases were considered to be related to exposure and were consistent with the previous two-generation study[1] where increased estrous cycle lengths were observed at 700 ppm. Mean estrous cycle lengths could not be determined for two, one and two females in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, because no complete estrous cycles occurred for these females.

11.3.3.2. SECOND MATING

Summary Data: Tables 49, 50

Individual Data: Tables 155, 156

Historical Control Data: Appendix I

The F_1 females were between 181 and 190 days old at the initiation of the second breeding period. For the second F_1 pairing, mean numbers of days between pairing and coitus (2.3, 1.4, 2.5, 2.1 and 2.0 days in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively) were generally comparable across all groups on study and were also comparable to WIL historical control data for this endpoint (mean of 2.7 days and a range of 2.0 to 3.5 days), with the following exception. The mean value for group 2 (700/700-D22 ppm; 1.4 days) was below the historical control range. In contrast, the pre-coital intervals for animals exposed to D_4 at 700 ppm in the previous two-generation study (WIL-51036[1]) were 3.2 for the F_0 generation and 3.3 and 2.4 for the F_1 generation for the first and second mating periods, respectively. The reduced pre-coital interval in the 700/700-D22 ppm group may have contributed to the reduced fertility observed in this group but cannot be determined with certainty.

Female mating indices were determined to be 86.7%, 93.1%, 96.3%, 100% and 90.0% in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively; none of the differences were statistically significant. Four, two, one and three females in the control, 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, had no evidence of mating and did not deliver a litter. No test article-related effect on mating index was demonstrated for any group. Female fertility indices in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups were 76.7%, 58.6%, 77.8%, 86.7% and 70.0%, respectively, when calculated using the EPA method and 88.5%, 63.0%, 80.8%, 86.7% and 77.8%, respectively, when calculated using the OECD method (refer to Section 10.2.2. for a description of the EPA and OECD calculation methods). None of the differences from the control group were statistically significant. These results were qualitatively similar to what was seen in the first mating period for these F_1 animals. Despite the fact that the changes were not statistically significantly different from the control group, the reduced fertility in the 700/700-D22 ppm group was considered to be test article-related. The lower fertility rate in the 700/700-D22 ppm group was the result of 10 females that had evidence of mating that were determined to be nongravid compared to only three females in the control group. The lower fertility rate in the 700/700-D22 ppm group compared to the other two groups of F_1 females exposed to D_4 was attributed to the fact that only the females in the 700/700-D22 group were exposed indirectly to D_4 *in utero* and during the pre-weaning period and directly to 700 ppm D_4 beginning on PND 22. This reduced fertility was consistent with the reduced fertility observed in the previous two-generation study (WIL-51036[1]). However, unlike the previous study, no reductions in mating indices were observed in the groups exposed to D_4.

Individual variation in the estrous cycle occurred in all study groups. Mean estrous cycle lengths were 5.1, 5.0, 4.4, 4.4 and 5.0 days in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. The differences from the control group were not statistically significant, and the values were all within the expected range for this

parameter based upon the WIL historical control data (mean of 4.3 days, ranging from 4.1 to 5.1 days). Mean estrous cycle lengths could not be determined for five, four and one females in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, because no complete estrous cycles occurred for these females.

11.3.4. BODY WEIGHTS

11.3.4.1. WEEKLY

Summary Data: Tables 51, 52, 53, Figure 4

Individual Data: Tables 157, 158

Mean F_1 weekly body weights, body weight gains and cumulative body weight changes (from study week 8) were unaffected by test article exposure at the 700 ppm concentration. A statistically significant increase ($p<0.05$) in mean body weight in the 0/700 ppm group during study week 31 and a decrease ($p<0.01$) in mean body weight gain in the 700/700-D44 ppm group during study week 10-11 were noted. These changes were not considered to be of toxicological relevance.

11.3.4.2. GESTATION

11.3.4.2.1. FIRST MATING

Summary Data: Tables 54, 56, Figure 5

Individual Data: Tables 159, 161

Mean body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were similar to the control group during gestation days 0-7, 7-10 and 10-14; none of the differences were statistically significant. Mean body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were slightly reduced (not statistically significant) by the end of the gestation period (gestation days 14-20) and when the entire gestation period (gestation days 0-20) was evaluated; these reductions were attributed to exposure. The mean body weight gain reduction late in gestation was considered to be reflective of the subsequently observed reduced mean numbers of pups born at 700 ppm. These reductions in body weight gain were not of sufficient magnitude to produce any

reductions in mean body weights; none of the differences were statistically significant. Similar reductions in mean body weight gain during gestation days 14-20 were noted in animals exposed to 700 ppm D_4 in the previous two-generation study (WIL-51036[1]) due to a reduction in the number of fetuses developing *in utero* as evidenced by a reduced number of pups born. Mean body weights and body weight gains in the 700/0 ppm group were similar to the control group values throughout gestation.

11.3.4.2.2. SECOND MATING

Summary Data: Tables 55, 57, Figure 6
Individual Data: Tables 160, 162

Mean body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were generally slightly decreased during gestation days 0-7 and 7-10 compared to the control group values; however, the differences were not statistically significant and no consistent effects across D_4 exposed groups were apparent. During gestation days 10-14, mean body weight gains in the 700/700-D22 and 0/700 ppm groups were reduced compared to the control group; the difference in the 700/700-D22 ppm group was statistically significant at $p<0.01$. During gestation days 14-20, mean body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were decreased compared to the control; again, the 700/700-D22 ppm group value was statistically significant at $p<0.05$. Because of the decreased mean body weight gains noted later in gestation, overall mean gestation body weight gains (gestation days 0-20) in all 700 ppm groups were reduced compared to the control group with a more pronounced statistically significant ($p<0.01$) effect noted in the 700/700-D22 group. Mean body weights in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were generally similar to and not statistically significant different from the control group.

Mean body weights and body weight gains in the 700/0 ppm group were similar to the control group during gestation.

11.3.4.3. LACTATION

11.3.4.3.1. FIRST MATING

Summary Data: Tables 58, 60, Figure 7

Individual Data: Tables 163, 165

Mean body weights and body weight gains were unaffected by test article exposure during the first F_1 lactation period. No statistically significant differences from the control group were observed.

11.3.4.3.2. SECOND MATING

Summary Data: Tables 59, 61 Figure 8

Individual Data: Tables 164, 166

Mean body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were decreased (not statistically significant) compared to the control group during lactation days 1-4. Mean body weights were unaffected by test article exposure during the second F_1 lactation period. No statistically significant differences from the control group were observed.

Mean body weights and body weight gains in the 700/0 ppm group were similar to the control group values.

11.3.5. FOOD CONSUMPTION

11.3.5.1. WEEKLY

Summary Data: Tables 62, 63, 64

Individual Data: Tables 167, 168, 169

Weekly food consumption (evaluated as g/animal/day and g/kg/day) and food efficiency were unaffected by test article exposure in the F_1 females throughout the study. A few statistically significant ($p<0.05$ or $p<0.01$) differences from the control group were noted in one or more exposed groups throughout the study; however, no consistent effects across D_4 exposed groups were apparent that would suggest a test article-related effect.

11.3.5.2. GESTATION

11.3.5.2.1. FIRST MATING

Summary Data: Tables 65, 67, 69

Individual Data: Tables 170, 172, 174

Food consumption (evaluated as g/animal/day and g/kg/day) in the 700 ppm F_1 groups (Groups 2, 3 and 5) during the first gestation period was unaffected by test article exposure. No statistically significant differences from the control group were observed.

Food efficiency in the 700/700-D22, 700/700-D44 and 0/700 ppm groups during the first F_1 gestation period was similar to the control group during gestation days 0-7, 7-10 and 10-14. During gestation days 14-20 and when the entire gestation period (gestation days 0-20) was evaluated, food efficiency was reduced (not statistically significant) in these groups relative to the control group, because of decreased mean body weight gains without concurrent decreases in food consumption. Food efficiency in the 700/0 ppm group was similar to the control group throughout the first F_1 gestation period.

11.3.5.2.2. SECOND MATING

Summary Data: Tables 66, 68, 70

Individual Data: Tables 171, 173, 175

Food consumption (evaluated as g/animal/day and g/kg/day) during the second F_1 gestation period was unaffected by test article exposure at 700 ppm. Statistically significantly ($p<0.05$ or $p<0.01$) reduced g/kg/day food consumption values were noted in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups relative to the control group during gestation days 0-7 and 7-10. These changes were not considered to be toxicologically relevant because they were minimal in magnitude, were not noted for the g/animal/day values and occurred similarly in the groups exposed to the test article and one of the groups receiving filtered air.

Mean food efficiency in the 700 ppm groups was similar to the control group values during gestation days 0-7 and 7-10. Mean food efficiency was reduced in the

700/700-D22 and 0/700 ppm groups during gestation days 10-14, in all three 700 ppm groups during gestation days 14-20 and subsequently, for the entire gestation period (gestation days 0-20); the differences in the 700/700-D22 group were statistically significant ($p<0.01$) compared to the control group. These reductions are the result of the test article-related reductions in mean gestation body weight gain that occurred without concurrent decreases in food consumption in these animals during this period. Mean food efficiency in the 700/0 ppm group was unaffected by test article exposure.

11.3.5.3. LACTATION

11.3.5.3.1. FIRST MATING

Summary Data: Tables 71, 73, 75

Individual Data: Tables 176, 178, 180

Food consumption (evaluated as g/animal/day and g/kg/day) during the first F_1 lactation period was slightly reduced in the 700/700-D22, 700/700-D44 and 0/700 ppm groups during lactation days 1-4, 4-7, 7-14, 14-21 and 1-21; these reductions were often statistically significant ($p<0.05$ or $p<0.01$) and were attributed to exposure. Food consumption in the 700/0 ppm group was unaffected by test article exposure during the first lactation period.

Mean food efficiency was unaffected by exposure to the test article during the first lactation period.

11.3.5.3.2. SECOND MATING

Summary Data: Tables 72, 74, 76

Individual Data: Tables 177, 179, 181

Food consumption (evaluated as g/animal/day and g/kg/day) and food efficiency were reduced in the 700/700-D22, 700/700-D44 and 0/700 ppm groups during the second lactation period (lactation days 1-4). Although none of the differences from the control group were statistically significant, the food consumption reductions were consistent with

the reductions observed during the first mating period and were therefore, attributed to exposure.

Food consumption and food efficiency in the 700/0 ppm group were similar to the control group values during the second lactation period.

11.3.6. GESTATION LENGTH AND PARTURITION

11.3.6.1. FIRST MATING

Summary Data: Table 77

Individual Data: Table 182

Historical Control Data: Appendix I

Mean gestation length for the first mating was not affected by exposure to the test article. The mean lengths of gestation were 22.1, 22.3, 22.2, 22.1 and 22.3 in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. No statistically significant differences from the control group were noted.

Female no. 80245-09 in the 700/700-D44 group delivered one pup on lactation day 0, following 22 days of gestation; however, this female was euthanized prior to completion of delivery (due to moribund condition, dystocia) and had 13 dead fetuses *in utero*. Female no. 80286-08 in the 700/700-D22 ppm group was euthanized *in extremis* on gestation day 29 due to two fetuses blocking the cervix. No other signs of dystocia or signs of extended gestation were in the remaining F_1 females following the first mating. However, female no. 80257-03 also in the 700/700-D44 ppm group was found dead on the expected day of parturition (gestation day 22).

11.3.6.2. SECOND MATING

Summary Data: Table 78

Individual Data: Table 183

Historical Control Data: Appendix I

Mean gestation length for the second mating was not affected by exposure to the test article. The mean lengths of gestation were 22.0, 22.2, 22.3, 22.3 and 22.4 in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. No statistically significant differences from the control group were noted. Female no. 80189-04 in the 700/700-D44 group delivered eight pups on lactation day 0 and was found dead with six fetuses *in utero*. Female no. 80124-06 in the 0/700 ppm group was found dead during the period of expected parturition (gestation day 23) with 14 fetuses *in utero*.

11.3.7. HORMONE ANALYSES

Summary Data: Table 79

Individual Data: Tables 184, 185

Mean estradiol levels in the exposure groups were similar to the control group for females euthanized on lactation day 4 and for those that failed to deliver. Mean progesterone levels in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were decreased (16.7, 9.9 and 15.0 ng/mL, respectively) relative to the control group value (20.5 ng/mL) for females that were euthanized on lactation day 4; the difference in the 700/700-D44 ppm group was statistically significant ($p<0.01$). However, because similar statistically significant reductions were not observed in the 700/700-D22 and 0/700 ppm groups, this decrease was not considered test article-related. For females that failed to deliver, mean progesterone level in the 700/0 ppm group was statistically significantly ($p<0.05$) increased (9.6 ng/mL; $n = 4$) than the control group value (2.3 ng/mL); no other statistically significant differences in mean progesterone levels were noted for the females that failed to deliver. Because the F_1 females in this group were not exposed to the test

article and a similar increase was not observed in this group for females that delivered, this increased progesterone level was not attributed to the test article.

Mean estradiol/progesterone (E/P) ratios for the lactation day 4 F_1 females that were exposed to D_4 were greater than for the lactation day 4 F_1 females exposed to filtered air. E/P ratios were 16.1, 22.7 and 17.6 pg/ng, in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, compared to 4.2 and 4.7 pg/ng in the 0/0 and 700/0 ppm groups, respectively. The difference in the 700/700-D44 ppm group was statistically significant ($p<0.05$). There was a strong correlation in the 700/700-D22, 700/700-D44 and 0/700 ppm groups of females with elevated E/P ratios and females with no complete basophilic corpora lutea, indicating that these females were slower to begin cycling after parturition than F_1 females exposed to filtered air. For females that failed to deliver, E/P ratios were highly variable among the 0/0, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups (72.1, 71.3, 29.7, 21.4 and 76.6 pg/ng, respectively); none of the differences were statistically significant compared to the control group. However, in all groups (including the control group), the E/P ratios for females that failed to deliver were higher than for females in the same exposure groups that delivered. The majority of the females that failed to deliver in the 700/700-D22, 700/700-D44 and 0/700 ppm groups also did not have basophilic complete corpora lutea and/or were cycling abnormally. Mean prolactin levels were decreased in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups (94.2, 91.5, 99.0, 65.7 ng/mL, respectively) when compared to the control group (223.4 ng/mL). However, because the control group value was atypically high, the decreases were not considered to be test article-related. The differences were statistically significant ($p<0.05$ or $p<0.01$). For females that failed to deliver, mean prolactin levels in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups were increased (83.9, 119.9, 61.4 and 66.8 ng/mL) when compared to the control group (38.6 ng/mL); none of the differences were statistically significant.

11.3.8. F_1 PATHOLOGY

11.3.8.1. MACROSCOPIC EXAMINATION

Summary Data: Tables 80, 81, 82, 83, 84

Individual Data: Tables 186, 187, 188, 189, 190

In the 700/700-D22, 700/700-D44 and 0/700 ppm groups, 1/30, 4/30 and 1/30 females, respectively, were found dead between weeks 22 and 34. Female no. 80286-08 in the 700/700-D22 ppm group was euthanized *in extremis* on gestation day 29 following the first breeding period. Two fetuses were blocking the cervix of this female; no other internal findings were noted. Four females in the 700/700-D44 group were found dead or euthanized *in extremis* and included the following. Female no. 80257-03 died on gestation day 22 following the first breeding period; this female had 12 fetuses *in utero* and no other internal findings. Female no. 80186-05 was euthanized *in extremis* on lactation day 5 following the first breeding period; this female had pale kidneys and white areas on the kidneys and on the median, left and caudate lobes of the liver. Female no. 80245-09 was euthanized *in extremis* on lactation day 0 following the first breeding period and had pale kidneys, a pale liver and 13 dead fetuses with no apparent malformations *in utero*; this female had previously delivered one pup. Female no. 80189-04 died on lactation day 0 following the second breeding period; this female had a pale pituitary gland, dark red contents in the stomach and six retained fetuses with no apparent malformations *in utero*; this female had previously delivered eight pups. In the 0/700 ppm group, female no. 80124-06 died on gestation day 23 following the second breeding period; this female had 14 fetuses with no apparent malformations *in utero* and no other internal findings. All other F_1 parental animals survived to the scheduled necropsy.

At the scheduled necropsies of the F_1 females, no exposure-related internal findings were noted. Findings in the exposed groups occurred infrequently or with similar frequency in the control group. No relationship to the test article exposure was evident.

11.3.8.2. ORGAN WEIGHTS

Summary Data: Tables 85, 86, 87, 88, 89, 90, 91, 92

Individual Data: Tables 191, 192, 193, 194, 195, 196, 197, 198

There were no test article-related effects on absolute or relative (to final body weight) uterine, ovarian, or pituitary weights for any group on study. No statistically significant differences from the control group were observed for organ weights. These results are in contrast to the increased pituitary weights observed in the 700 ppm group F_1 females in the previous two-generation study (WIL-50136[1]).

11.3.8.3. MICROSCOPIC EXAMINATION

Pathology Report: Appendix H

No test article-related effects were noted microscopically in the ovary, uterus, vagina, mammary gland or pituitary gland in any F_1 female. All F_1 females appeared to have essentially normal pregnancies. Although the estrous cycles of the F_1 females from weaning to necropsy were not yet totally normal, they were resolving in an expected manner without any recognizable exposure effect.

The ovaries and varying corpora lutea development indicated that the rats from all groups had been cycling. The numbers of basophilic new corpora lutea in the 700/700-D22 and 700/700-D44 and 0/700 ppm groups were less than the control and 700/0 ppm groups; however, the numbers of females with activated corpora lutea were approximately equal in all groups, including the control group. The exact cause for these differences was not clear; there was a suggestion that the F_1 females in the 700 ppm-exposed groups were beginning to recycle but may have been somewhat slower than the F_1 females in the filtered air-exposed groups.

The uterus and vagina of each female were similar among all groups including the control group. The 700/700-D22 and 0/700 ppm groups had 9/30 and 8/30 females, respectively, in proestrus, which was greater than the other groups. Mucification levels in the 700/700-D44 and 0/700 ppm groups were slightly increased compared to the control,

700/700-D22 and 700/0 ppm groups. However, these differences were not clearly different and no definitive reason could account for these changes.

The mammary gland had alveolar/lobular development with secretory activity. One, four, five, one and two females in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively, had duct ectasia.

The pituitary gland was essentially normal with a single 700/700-D22 group female that had a cyst.

11.3.9. F_2 LITTER DATA

11.3.9.1. PND 0 LITTER DATA AND POSTNATAL SURVIVAL

11.3.9.1.1. FIRST MATING

Summary Data: Tables 93, 95

Individual Data: Tables 199, 201

Historical Control Data: Appendix I

There were test article-related reductions in the mean numbers of F_{2a} pups born and the subsequent mean live litter sizes on PND 0 for the 700/700-D22, 700/700-D44, and 0/700 ppm groups following the first F_1 mating. Means for these parameters were reduced up to 33% in the exposed groups, and all reductions were statistically significant ($p<0.01$) compared to the control group. The mean number of pups born in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were 10.0, 9.5 and 10.1 pups per dam, respectively, compared to 13.7 pups per dam in the control group and 14.2 (range 12.0-16.3) pups per dam in the WIL historical control data. The reduced numbers of pups born and live litter size in the groups exposed to 700 ppm of D_4 were consistent with the reductions observed in the F_1 females exposed to 700 ppm of D_4 in a previously conducted two-generation study (WIL-51036[1]). The mean number of pups born and mean live litter size in the 700/0 ppm group were similar to the control group values. The percentage of males per litter at birth was unaffected by test article exposure in all groups.

Postnatal survival was slightly decreased in the 700/700-D22 group on PND 0; the difference was not statistically significant compared to the control group and no effects were noted in the remaining groups. There were slight, statistically significant reductions ($p<0.05$) in F_{2a} postnatal survival observed in the 700/700-D22 and 700/700-D44 ppm groups on PND 0-1; these reductions were considered related to test article-exposure. The postnatal survival values for the interval from birth to PND 4 for these groups were 87.5% and 89.4% per litter, respectively, compared to 96.2% per litter in the control group. These differences, although not statistically significant, were lower than the reported range in the WIL historical control data (mean of 96.2%, ranging from 91.3% to 99.3%). No other effects on pup survival were noted in the 700/700-D22 and 700/700-D44 ppm groups during PND 1-4, 4-7, 7-14, 14-21 and 4-21. Pup survival in the 700/0 and 0/700 ppm groups was unaffected by exposure. One female each in the 700/700-D22 and 700/700-D44 groups had total litter losses by lactation day 5.

11.3.9.1.2. SECOND MATING

Summary Data: Tables 94, 96

Individual Data: Tables 200, 202

Historical Control Data: Appendix I

There were test article-related reductions in the mean numbers of F_{2b} pups born and the subsequent mean live litter sizes on PND 0 for the 700/700-D22, 700/700-D44, and 0/700 ppm groups following the second F_1 mating; means for these parameters were reduced up to 34% in the exposed groups and replicated the reductions in these groups observed during the first F_1 mating period. The differences in the 0/700 ppm group were statistically significant ($p<0.05$) compared to the control group. The mean number of pups born in the 700/700-D22, 700/700-D44 and 0/700 ppm groups were 9.3, 9.7 and 8.9 pups per dam, respectively, compared to 12.7 pups per dam in the control group and 14.2 (12.0-16.3) pups per dam in the WIL historical control data. The mean number of pups born and mean liver litter size in the 700/0 ppm group were similar to the control

group values. The percentage of males per litter at birth was unaffected by test article exposure in all groups.

Postnatal pup survival in the 700/700-D44 and 0/700 ppm groups (86.3% and 88.2% per litter, respectively) was reduced compared to the control group (93.1% per litter) from birth to PND 4. Although the differences were not statistically significant, the values were below the minimum mean value in the WIL historical control data (91.3% per litter) and were considered related to test article exposure. Pup survival (percent per litter) was not affected by parental exposure in the 700/700-D22 and 700/0 ppm groups from birth to PND 4. No statistically significant differences from the control group were noted. One and two females in the control and 700/700-D44 groups had total litter losses by lactation day 2.

11.3.9.2. GENERAL PHYSICAL CONDITION AND MORTALITIES

11.3.9.2.1. FIRST MATING

Summary Data: Table 97

Individual Data: Table 203

Pups from the first F_1 mating (F_{2a} pups) which were found dead numbered 14, 25, 29, 7 and 9 in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively. In the same respective groups, 2, 5, 5, 1 and 3 pups were missing and presumed to have been cannibalized. The general physical condition of the F_{2a} pups during lactation was similar across all groups on study, with the following exception. Thirteen, 26, 6 and 8 pups in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, respectively, were small in size compared to two pups in the control group.

11.3.9.2.2. SECOND MATING

Summary Data: Table 98

Individual Data: Table 204

Pups from the second F_1 mating (F_{2b} pups) which were found dead numbered 6, 9, 4, 7 and 24 in the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups,

respectively. In the control, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups, 10, 1, 7, 4 and 0 pups, respectively, were missing and presumed to have been cannibalized. The general physical condition of the F_{2b} pups during lactation was similar across all groups on study.

11.3.9.3. OFFSPRING BODY WEIGHTS

11.3.9.3.1. FIRST MATING

Summary Data: Tables 99, 101, Figures 9, 10

Individual Data: Tables 205, 207

Historical Control Data: Appendix I

Mean F_{2a} offspring body weights and body weight gains were increased in the 700/700-D22, 700/700-D44 and 0/700 ppm groups during PND 1 to 4. These increases were attributed to the exposure-related reductions in the mean number of pups born and mean live litter sizes noted in these groups. As a result of decreased mean body weight gains in these groups during PND 4 to 7, mean body weights in all D_4-exposed groups were similar to the control group on PND 7. Mean body weight gains in all D_4-exposed groups continued to be lower than the control group throughout the remainder of lactation, resulting in decreased mean pup body weights on PND 14 and 21. The differences from the control group were often statistically significant ($p<0.05$ or $p<0.01$). Mean F_{2a} offspring body weights and body weight gains in the 700/0 ppm group were similar to the control group.

11.3.9.3.2. SECOND MATING

Summary Data: Tables 100, 102, Figures 11, 12

Individual Data: Tables 206, 208

Historical Control Data: Appendix I

Test article-related increases were observed in mean offspring (male and female) body weight gains in the 0/700 ppm group during lactation days 1-4. Mean male and female offspring body weights were increased in this group on PND 1 and 4. With the exception

of female mean body weight on PND 1, the differences in mean body weights from the control group were statistically significant ($p<0.05$ or $p<0.01$) and were attributed to the decreased mean live litter size that was observed for this group. Mean offspring body weights and body weight gains in the 700/700-D22, 700/700-D44 and 700/0 ppm groups were similar to the control group values; no statistically significant differences were noted.

11.3.9.4. NECROPSIES OF PUPS FOUND DEAD OR EUTHANIZED DUE TO DEATH OF DAM

11.3.9.4.1. FIRST MATING

Summary Data: Tables 103, 105

Individual Data: Tables 209, 211

No internal findings that could be attributed to F_1 exposure were noted at the necropsies of F_{2a} pups that were found dead or euthanized due to the death of the dam. One control group animal had red fluid contents in the stomach. Aside from the presence or absence of milk in the stomach, no other internal findings were noted.

11.3.9.4.2. SECOND MATING

Summary Data: Tables 104, 106

Individual Data: Tables 210, 212

No internal findings that could be attributed to F_1 exposure were noted at the necropsies of F_{2b} pups that were found dead or euthanized due to the death of the dam. Aside from the presence or absence of milk in the stomach, no internal findings were noted.

12. CONCLUSIONS

The current study was conducted to gain mechanistic insights into the previously demonstrated reproductive toxicity in F_1 generation Sprague-Dawley rats exposed to octamethylcyclotetrasiloxane (D_4) for 6 hours daily during different windows of development. Four exposure groups and a concurrent control group were utilized in this design:

- Group 1 (filtered air control group) females were exposed to filtered air only throughout the study in the F_0 and F_1 generations.
- Group 2 (700/700-D22 ppm) females were exposed to D_4 throughout the study; the F_0 generation was exposed beginning 7 days prior to mating and continuing until euthanasia and the F_1 generation was exposed to D_4 beginning on PND 22 and continuing through two mating periods.
- Group 3 (700/700-D44 ppm) females were exposed to D_4 throughout the study; the F_0 generation was exposed beginning 7 days prior to mating and continuing until euthanasia, and the F_1 generation was exposed to D_4 beginning on PND 44 and continuing through two mating periods.
- Group 4 (700/0 ppm) F_0 females were exposed to D_4 during the entire F_0 generation; however, F_1 animals were only exposed to filtered air throughout both mating periods.
- Group 5 (0/700 ppm) F_0 females were exposed filtered air during the F_0 generation; F_1 offspring were exposed at D_4 beginning at weaning (PND 21) and continuing throughout both mating periods.

In the previous two-generation reproductive toxicity whole-body inhalation study of D_4[1], reduced fertility was observed for F_1 females exposed at 700 ppm. In the first mating of F_1 females, the reduced fertility was observed following *in utero*/nursing exposure and approximately 15 weeks of direct exposure (10 weeks pre-mating, 2-week mating, and a 3-week gestation period). Direct test exposures for these rats initiated at approximately 3 weeks of age. A second mating of the F_1 generation was performed and further reduced fertility was observed following an additional approximately 12 weeks of direct exposure (3-week lactation period, 4-week latent period, 2-week mating period, and 3-week gestation period). Although the males used for these matings were exposed to the test article, a further mating of these males to naive females showed no fertility effect on the

males, thereby demonstrating the reduced fertility was a female-specific phenomenon. No significant effect on fertility was observed in the F_0 generation, in which no *in utero*/nursing exposure occurred, and direct exposures initiated at approximately 6 weeks of age. Therefore, the current study employed exposed females and unexposed males and focused on the F_1 generation.

In the current study, exposure of females to 700 ppm D_4 resulted in generally the same profile of reproductive toxicity that was demonstrated previously. In the previous two-generation study[1], adverse reproductive effects noted in the females exposed to 700 ppm D_4 included dystocia (F_0 generation), reduced fertility (F_1 generation) and reduced live litter size (F_0 and F_1 generations). In the current study, one and three F_1 females in the 700/700-D22 and 700/700-D44 ppm groups, respectively, died between gestation day 22 to lactation day 5 following the first mating period and one F_1 female in both the 700/700-D44 and 0/700 ppm groups died on lactation day 0 and on gestation day 23, respectively, following the second mating. Evaluation of the in-life and *postmortem* data for the F_1 females that died prior to scheduled euthanasia revealed that the deaths were likely related to dystocia. No mortality was observed in the F_0 generation.

Reductions in mean live litter sizes and mean number of pups born were observed in all groups of F_0 and F_1 females exposed to 700 ppm D_4 following all mating periods. The differences were statistically significant for the F_0 females, the F_1 females following the first mating period and only the F_1 females in the 0/700 ppm group following the second mating period. As a result, increased (often statistically significant) mean offspring body weights were noted in all 700 ppm groups for the F_1 and F_{2a} offspring and 0/700 ppm group for the F_{2b} offspring. Offspring body weight gains in the 700/700-D22, 700/700-D44 and 0/700 ppm groups from the F_{2a} generation were decreased during PND 4-7, 7-14 and 14-21. Postnatal survival was reduced (not statistically significant) from birth to PND 4 in the 700/700-D22 and 700/700-D44 ppm groups for the F_{2a} offspring and for the 700/700-D44 and 0/700 ppm groups for the F_{2b} offspring.

There were no adverse effects on mating and fertility indices in the F_0 generation. However, one and four F_0 females from the 700/700-D22 and 700/0 ppm groups, respectively, were in the process of total litter resorption at the time of euthanasia on post-mating day 25. In the F_1 generation, fertility indices (OECD and EPA methods of calculation) were reduced (not statistically significant) in the 700/700-D22 ppm group for both the first and second F_1 mating periods. Estrous cycle length in the F_1 700/700-D22 and 0/700 ppm groups was also increased (not statistically significant) when compared to the control group for the first mating period but was comparable for the second mating period. In addition, one F_1 female in both the 700/700-D22 and 700/700-D44 groups failed to deliver following the first mating period and was found to be gravid, and two, one and one F_1 females in the 700/700-D22, 700/700-D44 and 0/700 ppm groups, respectively, failed to deliver following the second mating period and were found to be gravid.

No test article-related clinical or macroscopic findings were noted in either maternal generation. No test article-related microscopic findings or effects on reproductive organ weights were noted for any F_1 female group.

No clear exposure-related effects on mean estradiol, progesterone and prolactin levels were noted for F_1 females on lactation day 4. For F_1 females that failed to deliver, mean estradiol and progesterone levels were not affected by exposure; however, mean prolactin levels in the 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups were increased when compared to the control group; none of the differences were statistically significant. Estradiol/progesterone (E/P) ratios for F_1 females on lactation day 4 in the D_4-exposed groups (700/700-D22, 700/700-D44 and 0/700 ppm groups) were increased compared to the groups receiving filtered air (0/0 and 700/0 ppm groups); the difference in the 700/700-D44 ppm group was statistically significant. The higher E/P ratios in the D_4-exposed F_1 females correlated with an increased number of females in these groups with no complete basophilic corpora lutea, indicating that these females were slower to begin cycling after parturition than the F_1 females exposed to filtered air. For females

that failed to deliver, E/P ratios were highly variable among the 0/0, 700/700-D22, 700/700-D44, 700/0 and 0/700 ppm groups; none of the differences were statistically significant compared to the control group. However, in all groups (including the control group), the E/P ratios for females that failed to deliver were higher than for females in the same exposure groups that delivered. In addition, the majority of the F_1 females that failed to deliver in the D_4 exposure groups did not have basophilic complete corpora lutea and/or were cycling abnormally.

Concentrations of D_4 in the plasma, liver and fat samples of F_0 females exposed to 700 ppm beginning 7 days prior to mating through gestation day 20 demonstrated that exposure occurred. When expressed on a μg/g basis, D_4 levels in fat were approximately 13- and 74-fold higher than in the liver and plasma, respectively. D_4 levels in these same tissues were measurable following indirect exposure to gestation day 20 fetuses and PND 21 weanlings and following direct exposure to F_1 females on PND 22-26. In all cases, the highest offspring concentrations were observed in fat. For both fat and liver, the highest concentrations of D_4 were observed in the PND 22-26 exposed females followed by the gestation day 20 fetuses. In contrast, plasma D_4 levels were higher in the gestation day 20 fetuses than in the PND 22-26 exposed females. For all samples evaluated, the lowest levels were measured in the indirectly exposed PND 21 weanlings. The D_4 levels in the plasma, liver and fat were 4.8-, 1.5- and 4.7-fold lower, respectively, in the PND 22-26 exposed F_1 females than in the F_0 females.

While F_1 female exposure to D_4 clearly produced reproductive toxicity (decreased live litter size), it would appear that initiating direct exposure at 6 weeks of age instead of at 3 weeks of age resulted in slightly less toxicity as demonstrated by fertility rates in the 700/700-D44 ppm group that were similar to the control group while the fertility rates in the 700/700-D22 and 0/700 ppm groups were slightly lower (but not statistically significant) than the control group. Additionally, exposure of D_4 only to the F_0 females (700/0 ppm group) resulted in no adverse reproductive effects for the F_1 females. The live litter size of F_1 females was reduced in the absence of F_0 maternal exposure

(0/700 ppm group) to virtually the same extent as when exposures initiated in the F_0 females (700/700-D22 ppm group). Therefore, *in utero* exposure to D_4 is not required to produce an adverse female reproductive outcome.

14. DEVIATIONS FROM THE PROTOCOL

This study was conducted in accordance with the protocol and protocol amendments, except for the following.

- **Section 9.2.2.** A stability sample was not collected for drum no. 2 and a purity sample was not collected for drum no. 3 of the test article for analysis.
- **Section 9.2.3.** The protocol required environmental data (temperature, humidity and/or negative pressure) and/or concentration to be recorded every 30 minutes, however, the following exceptions were noted. On December 25, 2001 (all chambers), January 1, 2002 (chambers 1 and 2), January 12, 2002 (chamber 2), March 26, 2002 (all chambers), April 27, 2002 (all chambers) and June 28, 2002 (chamber 2) environmental data and/or concentrations were not recorded for one or two of the 30-minute sampling times during those days.
- **Section 9.2.3.** On June 27, 2002, chambers 1 and 2 were not sampled during the 11^{th} sampling round; there was a 57-minute interval during which chambers 1 and 2 were not sampled. Room air was not sampled during the 12^{th} sampling round; the last sample was collected following 5 hours 10 minutes of exposure.
- **Section 9.2.4.** On April 20, 2002 (gestation day 20), dam no. 80193-09 in the control group showed signs of early parturition at the time inhalation chambers were loaded; therefore, exposure for this female was suspended and the female was not exposed on gestation day 21.
- **Section 9.2.4.** On December 17, 2001 (lactation day 5), F_0 animal nos. 80193 in the control group, 80241 in the 700/700-D22 ppm group and 80258 in the 700/0 ppm group were inadvertently not exposed; however, the animals were exposed on the following day (lactation day 6).
- **Section 9.2.4.** On February 13, 2002, exposure for the test article-exposed groups was 20 minutes longer than the protocol-required 6 hours.
- **Section 9.6.** The room temperature was above the protocol-specified range on November 19, 2001 (first day of breeding).
- **Section 9.7.** At randomization for the F_0 females, the body weight range was expanded to 228-292 g for the main study animals and 240-279 g for the satellite phase animals.
- **Section 10.1.1.** During the week of December 2-8, 2001, detailed physical examinations were recorded twice.
- **Section 10.1.2 and 10.1.3.** On July 15, 2002 (lactation day 1), body and food weights were not collected for animal no. 80284-08 in the 0/700 ppm group.

DEVIATIONS FROM THE PROTOCOL (CONTINUED)

- **Section 10.4.1.** On April 21, 2002, F_{2a} found dead pup nos. 1, 2 and 3 of dam no. 80222-08 in the 700/0 ppm group did not receive a gross necropsy examination.
- **Section 10.5.1.** On December 18, 2001, F_0 female no. 80218 in the 700/0 ppm group was euthanized by isoflurane on post-mating day 25 instead of by carbon dioxide inhalation.
- **Section 10.5.2.** Although not required by protocol, the following PND 21-28 unselected F_1 animals received gross necropsies: no. 80136-13 in the control group, no. 80126-10 in the 700/700-D22 group, nos. 80153-11, 80182-08 and 80227-07 in the 700/700-D44 group, nos. 80278-06 and 80277-01 in the 700/0 ppm group and no. 80289-14 in the 0/700 ppm group. These data will not be reported but will be maintained in the raw data.
- **Section 10.6.2.** There was no documentation that the capillary tubes used for fetal blood collection on December 10, 11, 12 and 15, 2001 were heparinized or that the December 12, 2001 fetal blood samples were placed in ice water following collection. In addition, according to the documentation in the study records, the fetal blood samples were collected from the vena cava instead of the umbilical vein on December 11, 2001.
- **Section 10.7.2.** At necropsy, organ weights were not collected for F_0 female no. 80207 in the 0/700 ppm group.
- **Section 10.7.3.** Samples collected at necropsy for hormone analysis from the F_1 lactation day 4, post-mating day 25 and post-cohabitation day 25 females (collected from July 15-29, 2002) were frozen in a -20°C freezer but were then transferred to a -70°C freezer on August 16, 2002.
- **Section 10.8.** Histopathologic findings in the test article-exposed groups were not compared to the filtered air control group using a two-tailed Fisher's Exact test as required by protocol; no statistics were performed on these findings.
- **Appendix B.** On January 12, 2002, the teflon tubing used to transfer vapors was changed over to a glass 18" x ½" I.D. beaded pipe.

These deviations did not negatively impact the quality or integrity of the data nor the outcome of the study.

NOTE: FOR THE PURPOSE OF CALCULATING MATING INDICES, POSITIVE EVIDENCE OF MATING WAS CONSIDERED TO INCLUDE THE PRESENCE OF SPERM ON A SLIDE FOLLOWING VAGINAL LAVAGE, OBSERVATION OF A COPULATORY PLUG, AND/OR IF THE FEMALE WAS FOUND TO BE GRAVID.
PRE-COITAL INTERVALS NOT SIGNIFICANTLY DIFFERENT FROM CONTROL GROUP USING DUNNETT'S TEST
MATING AND FERTILITY INDICES NOT SIGNIFICANTLY DIFFERENT FROM CONTROL GROUP USING CHI-SQUARE TEST
NA = NOT APPLICABLE

DOW CORNING CORPORATION
HEALTH AND ENVIRONMENTAL SCIENCES
TECHNICAL REPORT

WIL Research Laboratories, LLC
1407 George Road
Ashland, Ohio 44805

Report No.:	2004-I0000-54361
Title:	An Inhalation F_1 Generation Reproductive Toxicity Study of Octamethylcyclotetrasiloxane (D_4) in Female Sprague-Dawley Rats
Study No.:	9621
External Testing Facility No.:	WIL-51086
Test Article:	Octamethylcyclotetrasiloxane (D_4)
Study Director:	Donald G. Stump, Ph.D., D.A.B.T. Associate Director, Developmental and Reproductive Toxicology
Sponsor:	Dow Corning Corporation 2200 W. Salzburg Road Midland, Michigan 48686-0994
Sponsor Representative:	Waheed H. Siddiqui, Ph.D. Associate Toxicology Scientist
Testing Facility:	WIL Research Laboratories, LLC 1407 George Road Ashland, Ohio 44805
Study Completion Date:	January 17, 2005
Security Statement:	This report may be reproduced and shared with any Dow Corning employee. The director of the issuing department must approve distribution outside the corporation. When this INTERNAL report is no longer needed, it must be destroyed in a manner that safeguards against unauthorized disclosure.

DOW CORNING CORPORATION
HEALTH AND ENVIRONMENTAL SCIENCES
TECHNICAL REPORT

WIL Research Laboratories, LLC
1407 George Road
Ashland, Ohio 44805

Report No.:	2004-I0000-54361
Title:	An Inhalation F_1 Generation Reproductive Toxicity Study of Octamethylcyclotetrasiloxane (D_4) in Female Sprague-Dawley Rats
Study No.:	9621
External Testing Facility No.:	WIL-51086
Test Article:	Octamethylcyclotetrasiloxane (D_4)
Study Director:	Donald G. Stump, Ph.D., D.A.B.T. Associate Director, Developmental and Reproductive Toxicology
Sponsor:	Dow Corning Corporation 2200 W. Salzburg Road Midland, Michigan 48686-0994
Sponsor Representative:	Waheed H. Siddiqui, Ph.D. Associate Toxicology Scientist
Testing Facility:	WIL Research Laboratories, LLC 1407 George Road Ashland, Ohio 44805
Study Completion Date:	January 17, 2005
Security Statement:	This report may be reproduced and shared with any Dow Corning employee. The director of the issuing department must approve distribution outside the corporation. When this INTERNAL report is no longer needed, it must be destroyed in a manner that safeguards against unauthorized disclosure.

DOW CORNING CORPORATION
HEALTH AND ENVIRONMENTAL SCIENCES
TECHNICAL REPORT

WIL Research Laboratories, LLC
1407 George Road
Ashland, Ohio 44805

Report No.:	2004-I0000-54361
Title:	An Inhalation F_1 Generation Reproductive Toxicity Study of Octamethylcyclotetrasiloxane (D_4) in Female Sprague-Dawley Rats
Study No.:	9621
External Testing Facility No.:	WIL-51086
Test Article:	Octamethylcyclotetrasiloxane (D_4)
Study Director:	Donald G. Stump, Ph.D., D.A.B.T. Associate Director, Developmental and Reproductive Toxicology
Sponsor:	Dow Corning Corporation 2200 W. Salzburg Road Midland, Michigan 48686-0994
Sponsor Representative:	Waheed H. Siddiqui, Ph.D. Associate Toxicology Scientist
Testing Facility:	WIL Research Laboratories, LLC 1407 George Road Ashland, Ohio 44805
Study Completion Date:	January 17, 2005
Security Statement:	This report may be reproduced and shared with any Dow Corning employee. The director of the issuing department must approve distribution outside the corporation. When this INTERNAL report is no longer needed, it must be destroyed in a manner that safeguards against unauthorized disclosure.
