Change pages (report cover, ES-3, 1-6, 3-2, 3-3, 4-3, 4-4, and 4-14) to the Final Human Health Risk Assessment, (CDM, November 9, 2007)

which are:

approved

approved as noted.....

for your review.....

for your files.....X

Hi Chris,

While incorporating EPA's October 18, 2007 comments to the On-Site Soils Remedial Investigation Report, I noticed that

there was a comment pertaining to the HHRA Executive Summary (Comment 4, Section 5.4 - Section ES.3, last paragraph)

that also applied to the Final HHRA. This comment was not included in EPA's October 11, 2007 or October 29, 2007 final

comments to the HHRA, therefore, this change was not incorporated in the Final HHRA that was transmitted to you Nov. 9th.

I have made the change to the HHRA (and other sections where it applied) and 3 sets of change pages are attached for your

insertion into the Final HHRA. Change pages will also go to DTSC & CH2M Hill. Please feel free to call if you have questions.

Re: Final Human Health Risk Assessment Report,
Omega Chemical Superfund Site, Whittier, California

Dear Mr. Lichens:

Enclosed is the final Human Health Risk Assessment (HHRA) for the Omega Chemical Superfund Site, Whittier, California. The HHRA incorporates the comments that were provided in the conditional approval letter submitted by the USEPA on October 11, 2007.

Should you have any questions, regarding the above, please contact me.

Sincerely,
Omega Chemical Site PRP Organized Group

Edward Modiano
Project Coordinator

Subject: Response to EPA Comments dated October 11, 2007 and October 29, 2007 on Human Health Risk Assessment for On-Site Soils, Omega Chemical Superfund Site (CDM, October 1, 2007)

Dear Mr. Lichens:

Below are OPOG's responses to EPA comments dated October 11, 2007 and October 29, 2007 to the Human Health Risk Assessment for On-Site Soils, Omega Chemical Superfund Site, CDM, dated October 1, 2007. The response to comments is organized by repeating the original EPA comment in italics followed by OPOG's response in regular text.

EPA COMMENTS – October 11, 2007

1. Section 4.4.1.6, Page 4-11, Exposure Time. *Change the residential exposure time assumption to 24 hours indoors. Although the existing exposure time of 26 hours is a conservative assumption, it is not a reasonable assumption given that there are only 24 hours in a day. The change in daily exposure from 26 to 24 hours is not expected to result in a substantial change in the overall risk estimates for residents, and will improve the defensibility of the report.*

Residential exposure was modified to include 24 hours of indoor air exposure and 0 hours of outdoor air exposure.

Location of Revisions: Text revisions on pages 4-9 and 4-11. Table changes made to Tables 4-1, 4-2, and 6-2 in the text and Appendix A3 RAGSD Tables A3-4.1, 7.5A&B, 7.6A&B, 7.7A&B, 9.5A&B, 9.6A&B, and 9.7A&B. Figure changes were made to Figures ES-3 and 4-1.

2. Table 7-2, Comparison of Modeled and Measured Air Concentrations. *Remove or modify this table since it does not appear to incorporate the most recent agency comments regarding the outdoor air emission calculations. If the table is modified, remove the reference to the RBCA toolkit, list the corrected modeled air concentrations, and compare modeled results for the above ground receptor (as opposed to trench worker) to measured results above ground.*

Mr. Chris Lichens
November 9, 2007
Page 2

This table already includes the updated values modified per the EPA's comments. However, the title of the table and the footnote were not updated. The title has been revised to "Comparison of Modeled Ambient Air with Measured Ambient Air Concentrations" to remove references to the construction worker and excavation. The footnote has been modified to read: "(1) Exposure point concentrations for soil gas were modeled using box model calculations to determine outdoor air concentrations. These concentrations are the EPC Outdoor Air values for industrial workers listed in Table 4-20." (Note that since the last version of the text, all of the table numbers after Table 4-5 have been renumbered to account for deleted Table 4-6.) Footnote for "NC" was also removed from Table 7-2. Associated text was also revised to remove references to the construction worker and excavation on page 7-5.

Location of Revisions: Revision to Table 7-2 and associated text on page 7-5.

3. Section 8, Page 8-2, Summary and Conclusions. Delete Section 8, which appears to be redundant. The report already contains an Executive Summary which summarizes results and presents conclusions. The Executive Summary is also more comprehensive in its presentation of findings.

Other modifications were made per EPA Comments – October 29, 2007.

Location of Revisions: See EPA Comments – October 29, 2007

4. Appendix D Site-Specific PRG Calculations.

PRG Estimates Based on Central Tendency (CTE) Remove the CTE based PRGs from the report. EPA previously requested that the cleanup goals be consistent with Superfund's concept of a reasonable maximum exposure (RME) (see EPA's comment letter dated 8/31/07). The subject document presents various possible cleanup goals, which avoids potential problems with omissions. However, with so many numbers presented in this Appendix, it is difficult to navigate through the various lists. Removing CTE estimates would reduce the Appendix size by about 50%.

CTE-based PRGs were removed from the report.

Location of Revisions: Deletion of Appendix D Tables D-1.1, 1.3, 1.5, 2.1, 2.3, and 2.5. Revisions made to Appendix D Tables D-3.1, 3.2, 3.3, and 4.1. Tables in Appendix D were renumbered accordingly.

Define "Ambient" Air or Replace with "Outdoor" Air Change the term "ambient" to "outdoor" air to contrast it with "indoor" air in the RAGS D type tables. This will improve the readability and consistency of the document. Without this change, it could be argued that the term "ambient" applies to indoor air for an indoor worker. Alternatively, it would be acceptable to define the term ambient air as "outdoor air" in a footnote.

Mr. Chris Lichens
November 9, 2007
Page 3

The word "ambient" was revised to "outdoor" in the RAGS D tables in Appendix D3. Some tables and figures throughout the text were revised to replace "ambient" with "outdoor"; however, not all instances in the text were revised. Instead, a footnote stating, "Throughout the text, tables, and appendices of this report, "ambient air" is defined to be "outdoor air." The two terms are used interchangeably throughout this report." was added on page ES-2 of the executive summary and page 1-5 of the introduction.

Location of Revisions: Revisions made to Appendix A3 RAGS D tables and various tables and figures in the text. Footnotes added to pages ES-2 and 1-5.

Table D-4.2A Check this table for errors. The receptor population specified in the box, "Industrial Worker and Construction Worker", is not the same population that is indicated in the title for the table; namely, "Residential".

The receptor population stated in the box has been revised to state "Resident" and that the Receptors are "Adult, Adult/Child, Child". Values in table were correct as is.

Location of Revisions: Revision to text in Table D-4.2.

EPA COMMENTS – October 29, 2007

As a follow-up to our 10/29/07 conversation regarding the subject reports, please note that EPA will accept Section ES-6 of the 10/1/07 Human Health Risk Assessment (HHRA) as the conclusion section in the final HHRA, with the following modifications.

- *Section ES.6, the second bullet – Delete "The site is still surrounded by commercial industrial land use, is located on a major arterial, and possesses no characteristics that would suggest that would make it desirable for residential development." Note that this statement is incorrect since there is a residential area across the street from the former Omega property, and that EPA previously requested that OPOG delete this sentence (EPA letter of 4/9/07, page 4).*

Sentence was deleted.

Location of Revisions: Deletion of sentence on pages ES-6 and 8-2.

- *Section ES.6, the fifth bullet- Delete this bullet. The statement was invalidated by the results of the SVE pilot test.*

Bullet was deleted.

Location of Revisions: Deletion of bullet on pages ES-6 and 8-2.

Mr. Chris Lichens
November 9, 2007
Page 4

- *Section ES.6, the last bullet- Revise this bullet to read "if the site is deemed by EPA to pose an unacceptable risk."*

Bullet was revised.

Location of Revisions: Revision of bullet on pages ES-7 and 8-3.

- *Add the third paragraph of Section ES.5.1 to the final HHRA conclusions section ("Total cancer risk estimates for future commercial/industrial indoor air worker based on data...").*

These revisions, if accepted by OPOG, would modify comment 3 of EPA's 10/11/07 conditional approval letter regarding the HHRA, and the fourth bullet under comment 4 in EPA's 10/18/07 conditional approval letter regarding the On-Site Soils Remedial Investigation Report. No other aspects of either conditional approval letter would be changed by these revisions.

The indicated paragraph was added to Section 8 conclusions.

Location of Revisions: Addition of bullet on page 8-2.

Very truly yours,

Sharon Wallin, P.G.

Executive Summary

Executive Summary

This risk assessment presents an evaluation of potential human health risks and hazards associated with exposure to residual soil and groundwater contamination at the former Omega Chemical site (the Site). The Site is located at 12504/12512 East Whittier Boulevard (Figure ES-1). This Human Health Risk Assessment (HHRA) has been prepared in accordance with Task 2 of the Statement of Work in Consent Decree No. 00-12471 between the United States Environmental Protection Agency (USEPA) and the Omega Chemical Site PRP Organized Group (OPOG). The Consent Decree was lodged on November 24, 2000 and entered into the US District Court on February 28, 2001. This HHRA is consistent with the final On-site Soils Remedial Investigation/Feasibility Study Work Plan dated September 29, 2003.

Because the Site is located in an urban area that has been developed for decades, provides no suitable habitat, and contaminated subsurface soils are covered with buildings, asphalt, or concrete, ecological impacts from the facility are not expected and are not evaluated in this report. United States Environmental Protection Agency (USEPA) will be performing an evaluation of habitat and ecological receptors in a separate report.

ES.1 Approach

This HHRA follows risk assessment guidance from USEPA and with accommodations for consistency with similar guidance from California Environmental Protection Agency (CalEPA) as necessary.

The following tasks were performed as part of this risk assessment:

- Examined the history of the Omega Chemical site in Whittier, CA, and identified types of chemicals used and likely release mechanisms for these chemicals to enter the environment
- Evaluated data collected to characterize the site and existing contamination and used the most recent of these data to select chemicals of potential concern (COPCs) and to calculate exposure point concentrations
- Analyzed the potential for exposure to COPCs at the site through an evaluation of people that might be exposed, exposure pathways that might result in significant contact between these people and COPCs, and identification of exposure parameters appropriate for quantifying exposure resulting from this contact.
- Identified appropriate toxicity criteria for site COPCs
- Estimated risk to current and potential future receptors (people) that might contact contamination

- Evaluated uncertainties in data, exposure, toxicity and risk characterization aspects of the risk assessment
- Calculated health-based remediation goals (site-specific PRGs) for use in remediation decisions for the site

ES.2 Analytical Data

Data used in the HHRA were obtained from recent sampling events conducted by CDM. During the RI, samples were collected from surface soils, subsurface soils, soil gas, indoor air, and ambient air.¹ Sample locations are shown in Figures ES-2 and ES-2b and analytical summary tables for all samples collected during the RI are provided in the RI report. Selection of data used to support quantitative evaluation is based on quality, quantity, comparability (e.g., similar detection limits), and representativeness of data for current site conditions and potential exposures at the site. These data are then used in selection of COPCs and in estimation of exposure point concentrations used in the calculation of possible chronic daily intake. A more extensive discussion of data quality is provided in the pre-final On-Site Soils RI Report, which was submitted on June 20, 2007 (CDM, 2007).

ES.3 Exposure Pathways

Potentially exposed populations evaluated in the HHRA are future on-site residents, current and future on-site and off-site indoor industrial workers, future on-site outdoor industrial workers, and a future on-site construction worker. Currently, no plans exist for residential development at the Site, and the Site location suggests that residential development in areas adjacent to the Site is unlikely. The City intends to allow redevelopment that consists of commercial and retail uses with the construction of multi-level buildings. Specifically, City representatives have stated that it is unlikely that the Omega property will be redeveloped for residential uses (Adams, 2007), although the zoning of the site as the Whittier Boulevard Specific Plan-Workplace District allows for Live/Work units and multi-family housing. Therefore, although residential use of the site is not expected to occur in the future, quantitative analysis of future residential exposures is included to provide additional information to the risk manager. Section 4 provides a more detailed discussion of current and reasonable future land uses of the site.

The SCEM for soils at the Omega Site (Figure ES-3) includes theoretically feasible exposures and provides a basis for discussing the likelihood and importance of potential exposure pathways at the site. As illustrated in the SCEM, potential exposure pathways include:

- Oral/Dermal Contact with Surface Soil and Inhalation of Fugitive Dust - Current Industrial Worker

¹ Throughout the text, tables, and appendices of this report, "ambient air" is defined to be "outdoor air." The two terms are used interchangeably throughout this report.

- Inhalation of Indoor Air - Current Industrial Worker
- Inhalation of Ambient Air - Current Industrial Worker
- Oral/Dermal Contact with Regraded Surface/Subsurface Soil and Inhalation of Fugitive Dust – Future Residents, Future Industrial Indoor and Outdoor Workers, Future Construction Workers
- Inhalation of Indoor Air from Soil Gas – Future Residents and Future Industrial Indoor Workers
- Inhalation of Ambient Air from Soil Gas – Future Residents and Future Industrial Indoor Workers, Future Construction Workers, and Future Industrial Outdoor Workers

Currently, groundwater underlying the Site and in the immediate vicinity is not used for any purpose. Use for potable purposes within this area is also unlikely for the future due to the presence of high concentrations of total dissolved solids (TDS). TDS concentrations in groundwater samples from 2004 to 2006 ranged from 630 to 1,700 milligrams per liter (mg/L). The USEPA secondary standard for TDS in drinking water is 500 mg/L while the CalEPA maximum contaminant level (MCL) for drinking water ranges from 500 mg/L (recommended) to 1,000 mg/L (upper) with a short-term concentration of 1,500 mg/L. Use of groundwater at and downgradient of the site will be addressed in a separate report, and is not included in this risk assessment.

ES.4 Toxicity Assessment

The purpose of a toxicity assessment is to review and summarize available information on the potential for each COPC to cause adverse effects in exposed individuals. Risk characterization combines exposure information with toxicological criteria to estimate carcinogenic risks and non-carcinogenic hazards. Potential cancer risks and potential non-cancer hazards are separately calculated.

Cancer risks are estimated by multiplying exposure estimates for carcinogenic chemicals by corresponding cancer slope factors. The result is a risk estimate expressed as the odds of developing cancer. Commonly, risks (or odds) of developing cancer of one to 100 in one million (1×10^{-6} to 1×10^{-4}) or less are considered to fall within a potentially acceptable range, although decisions on the need for remediation or mitigation are made on a site-by-site basis. Lower risks are typically considered de minimis, while higher risks are often deemed unacceptable (EPA, 1992). In such instances, mitigation of risks may be considered necessary.

Chronic non-cancer hazard indices are calculated by dividing exposure estimates by reference doses. Reference doses are estimates of highest exposure levels that would not cause adverse health effects even if exposures continue over a lifetime. The ratio of exposure to reference dose is termed the hazard quotient (HQ). A HQ greater than one indicates an exposure greater than that considered safe. Impacts of exposure to multiple chemicals are accounted for by adding estimated HQs for non-carcinogenic chemicals that affect the same target organ or tissue in the body. Addition of HQs for COPCs that produce effects in similar organs and tissues results in a HI that reflects possible cumulative hazards.

ES.5 Risk Characterization

The risk assessment provides quantitative estimates of cancer risk and non-cancer hazard for people that might be exposed to exposure to residual soil and groundwater contamination.

ES.5.1 Cancer Risk

Total cancer risk estimates for current commercial/industrial worker on the Site parcel (Three Kings Construction CTE, 2E-5 to 9E-5 and RME, 4E-5 to 1E-4; Star City Auto Body CTE, 3E-5 to 6E-5 and RME, 4E-5 to 9E-5) are above the point of departure of one in one million but within the EPA risk range (Table ES-1). Cancer risks for the industrial/commercial indoor worker are primarily attributable to inhalation of indoor air. Figure ES-4 shows the cancer risks due to inhalation of indoor air for the different buildings. Inhalation of benzene accounts for 38 (Star City) to 46 (Three Kings) percent of the cancer risk. Onsite, sources at Star Auto Body and/or 3 Kings Construction could be responsible for some or all of the benzene detected in indoor air. Inhalation of methylene chloride accounts for 38 percent of the cancer risk for commercial/industrial workers at Three Kings, while inhalation of PCE accounts for 50 percent of the risk at Star City Auto Body (Figure ES-5).

For the other buildings, cancer risks were assessed only for the inhalation of vapors intruding into indoor air. Estimated inhalation cancer risks for these parcels were similar to, or lower than, those for the Site parcel, except for the West Parcel - Terrapave. All inhalation cancer risks were above the point of departure of one in one million but within the EPA risk range.

Total cancer risk estimates for future commercial/industrial indoor worker based on data from All Parcels (CTE, 9E-6 to 3E-4 and RME, 1E-5 to 5E-4) are above the EPA risk range (Table ES-2; Figure ES-6). Total cancer risk estimates for future commercial/industrial outdoor worker based on data from All Parcels (CTE, 1E-5 to 2E-5 and RME, 1E-5 to 2E-5) are above the point of departure of one in one million but within the EPA risk range. Cancer risks for the future industrial/commercial indoor worker are primarily attributable to inhalation of indoor air. PCE in soil gas accounts for 90 percent of the total inhalation risk. Cancer risks for future industrial/commercial outdoor worker are primarily attributable to exposure to COPCs in soil.

Total cancer risk estimates for the future construction worker (CTE, $2E-7$ to $4E-7$ and RME, $1E-06$ to $2E-6$) on the Site parcel; on the Others Parcels (CTE, $2E-7$ to $4E-7$ and RME, $1E-06$ to $2E-6$); and on All Parcels (CTE, $2E-7$ to $3E-7$ and RME, $1E-06$ to $2E-6$) are above the point of departure of one in one million but within the EPA risk range. Cancer risks for construction workers are primarily attributable to exposure to COPCs in soil. Benzo(a)pyrene accounts for about 44 to 48 percent of the cancer risk from soil exposure for construction workers (RME and CTE, respectively). PCB-1254 and total PCBs collectively accounts for about 25 to 28 percent of the cancer risk from soil exposure for construction workers (RME and CTE, respectively).

Total cancer risk estimates for future residents (adult, $5E-5$ to $3E-3$; adult+child, $8E-5$ to $3E-3$; and child, $4E-5$ to $1E-3$) on the Site parcel and on the Others Parcels (adult, $2E-5$ to $4E-3$; adult+child, $4E-5$ to $5E-3$; and child, $3E-5$ to $2E-3$) are above the EPA risk range (Figure ES-7). Cancer risks for residents are primarily attributable to inhalation of indoor air. Inhalation of PCE in soil gas accounts for 90 to 95 percent of the total inhalation risk.

ES.5.2 Chronic Non-Cancer Hazards

Chronic non-cancer hazards for the current commercial/industrial worker (Three Kings CTE, 0.4 to 1.2 and RME, 0.6 to 2; Star City Auto CTE, 0.5 to 5.1 and RME, 0.8 to 8) are above the threshold of 1. HIs for the current commercial/industrial worker are primarily attributable to inhalation of indoor air (Figure ES-8). HIs for the current commercial/industrial worker on the Site parcel at the Three Kings building are attributable to inhalation exposure to toluene (18 percent), m,p-xylenes (27 percent), methylene chloride (21 percent), PCE (12 percent), and benzene (12 percent).

Inhalation HIs for the five parcels are summarized as follows. HIs for the north parcel (Medlin and Sons, CTE, 0.09 to 0.6 and RME, 0.1 to 1; Medlin and Sons North, CTE, 0.05 and RME, 0.08) are primarily attributable to exposure to acetone (55 percent) with a lesser contribution from PCE (32 percent). HIs for the west parcel (TerraPave, CTE, 0.5 to 1.2 and RME, 0.7 to 1.8) are primarily attributable to exposure to PCE (90 percent). HIs for the south parcel - Bishop (CTE, 0.1 to 0.4 and RME, 0.2 to 0.6) are primarily attributable to exposure to PCE (76 percent) with a lesser contribution from 1,1-DCE (6 percent). HIs for the south parcel - LA Carts (CTE, 0.06 to 0.8 and RME, 0.1 to 1.3) are primarily attributable to exposure to toluene (74 percent) with a lesser contribution from acetone (15 percent). HIs for the south parcel - Oncology Care (CTE, 0.09 and RME, 0.14 to 0.15) are primarily attributable to exposure to toluene (20 percent), 1,2-DCA (23 percent), benzene (14 percent) and acetone (11 percent).

Total HIs for future residents (Site Parcel: adult, 0.7 to 30; adult+child 1.4 to 39; and child, 4.1 to 74; Other Parcels: adult, 0.4 to 45; adult+child 1 to 58; and child, 3.4 to 108) are above the target threshold (Figure ES-9). The highest HQs for residents are calculated from data from the Other Parcels and are attributable to inhalation exposure to PCE and 1,1-DCE, which account for 90 and 6 percent of HIs for the adult+child resident and 86 and 8 percent of HIs for the child adult+child resident on the Site Parcel.

Total HIs for future commercial/industrial indoor workers (CTE, 0.15 to 4 and RME, 0.3 to 7) based on data from All Parcels are above the target threshold (Figure ES-10). Inhalation of indoor air is attributable for most of this hazard. Similar to the resident, PCE and 1,1-DCE account for most of the hazard, contributing 84 and 9 percent, respectively. When the total HI is divided by target organ for the RME future commercial/industrial indoor worker, HI associated with liver is the largest portion (90 percent of the total HI, or an HI of 6.4). HIs for all other endpoints are less than the threshold of 1. Total HIs for future commercial/industrial outdoor worker (CTE, 0.2 to 0.3 and RME, 0.3 to 0.5) based on data from All Parcels are below the target threshold of one.

Total hazard indices for the construction worker (Site Parcel: CTE, 0.08 to 0.13 and RME, 0.8 to 1.2; Other Parcels: CTE, 0.08 to 0.12 and RME, 0.8 to 1.2; and All Parcels: CTE, 0.08 to 0.12 and RME, 0.08 to 1.1) are below or at the target HI of one. Roughly 30 percent of the hazards for the future construction worker are related to inhalation of ambient air. Hazards are higher on the Site Parcel than on the Other Parcels and All Parcels. HIs for all calculated endpoints (liver, body weight effects, and kidneys) are less than the threshold of 1.

ES.6 Conclusions

Important results of the risk assessment that follow from the HHRA can be summarized as follows:

- Field investigations since 2004 provide a recent and complete site characterization. High confidence can be assigned to use of these data to select chemicals of potential concern and to estimate exposure point concentrations.
- Commercial/industrial land use is an appropriate assumption for future site use. The site has been used for such purpose since it was developed from agricultural land in the 1950's. In addition, City representatives have stated that it is unlikely that the former Omega Chemical property will be redeveloped for residential uses (Adams, 2007), although the zoning of the site as Whittier Blvd. Specific Plan-Workplace District allows for Live/Work units and multi-family housing.
- Among receptors potentially exposed to site-related contaminants, the highest cancer risks and noncancer hazards are associated with exposure of hypothetical future residents, with risks above the EPA risk range and hazards above the target threshold.
- The pathway that suggests the highest potential for exposure involves intrusion of vapors into indoor air spaces. Inhalation of these vapors indoors results in the highest estimates of potential cancer risk and noncancer hazard.
- PCE is the primary COPC of concern at the site. For example, inhalation of indoor air suggests potential total inhalation cancer risks for current industrial workers ranging from $8E-6$ to $7E-5$. Cancer risk associated with inhalation exposure to

PCE alone ranges from 5E-7 to 4E-05. Estimated hazards for PCE were relatively low, however. HQs for exposure to indoor air for PCE ranged from 0.01 to 1.6 compared to a total inhalation HIs ranging from 0.06 to 8.

- Potential risks associated with exposure to ambient (urban background) concentrations of VOCs are as high as 3×10^{-5} and may account for 12 to essentially 100 percent of total risks estimated for indoor exposures, depending on parcel. LA Carts/Oncology Care may not be affected by site-related VOCs. Further, subsurface VOC contamination appears to be insufficient to sustain releases that would produce significant ambient air concentrations over extended periods of time.
- Ambient air risks for construction workers are within and near the lower end of the EPA risk range, and ambient air hazards are below the target threshold. . Subsurface VOC contamination appears to be insufficient to sustain releases that would produce significant ambient air concentrations over the one-year time period assumed for construction worker exposures.
- Hypothetical exposure to contaminants in soil is unlikely to occur, since soil is currently covered with buildings, asphalt, and concrete and such cover is likely to remain even if the site is redeveloped for other commercial/industrial purposes in the future. Even if the current property cover is replaced by green-belt type landscape, it is unlikely that contaminated soils would be exposed at the ground surface where direct contact (e.g., dermal contact or ingestion) could occur. Further, volatile COPCs, in particular PCE, acetone, and toluene, will not persist in non-volatile form in soils exposed during excavation, and direct contact exposures (incidental ingestion and dermal contact) for construction worker exposures via these pathways are expected to be minimal. These VOCs along with benzo(a)pyrene were associated with the bulk of risks and hazards estimated for direct contact exposure to surface soils.
- Uncertainties in the risk assessment suggest that site-related risks have been adequately characterized to support risk management decisions. In fact, the database is biased toward source/release areas and likely overstates levels of contamination for the site as a whole.
- Site-related risks involving exposure to PCE vapors in indoor air appear to be adequately assessed using available site-specific data.
- Site-specific PRGs developed for PCE can be used upon approval by EPA with confidence in evaluating remedial alternatives, if the site is deemed by EPA to pose an unacceptable risk.

(1) For future scenarios there is only one set of soil data for on-site.
(2) Indoor air pathway was calculated using soil gas data since future buildings are not expected to have the same characteristics as the current building where indoor air samples were measured
(3) Outdoor air exposure concentrations calculated from soil gas concentrations.
(4) Future residential development is unlikely for any area of the site. Calculations were only conducted on-site to provide a representative calculation for potential residential exposure.
(2) Indoor air pathway was calculated using soil gas data since future buildings are not expected to have the same characteristics as the current building where indoor air samples were measured.
(3) Ambient air exposure concentrations calculated from soil gas concentrations.
(4) Future residential development is unlikely for any area of the site. Calculations were only conducted on-site to provide a representative calculation for potential residential exposure.

Section 1

Section 1

Introduction

1.1 Scope and Objectives

This risk assessment presents an evaluation of potential human health risks and hazards associated with exposure to residual soil and groundwater contamination at the former Omega Chemical site (the Site). The Site is located at 12504/12512 East Whittier Boulevard (Figure 1-1). Because the Site is located in an urban area that has been developed for decades, provides no suitable habitat, and contaminated subsurface soils are covered with buildings, asphalt, or concrete, ecological impacts from the facility are not expected and are not evaluated in this report. United States Environmental Protection Agency (USEPA) will be performing an evaluation of habitat and ecological receptors in a separate report.

This Human Health Risk Assessment (HHRA) is consistent with the final On-site Soils Remedial Investigation/Feasibility Study Work Plan dated September 29, 2003 and follows risk assessment guidance from USEPA and with accommodations for consistency with similar guidance from California Environmental Protection Agency (CalEPA) as necessary. The following documents formed the basis for the HHRA:

- Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part A). Interim Final. EPA/5401/1-891002. December 1989.
- USEPA Risk Assessment Guidance for Superfund: Volume I. Human Health Evaluation Manual. Part B, Development of Risk-Based Preliminary Remediation Goals. Interim. U.S. EPA. Washington, D.C. 1991.
- USEPA Risk Assessment Guidance for Superfund. Vol. 1: Human Health Evaluation Manual, Part E, Supplemental Guidance for Dermal Risk Assessment. EPA/540/R/99/005. 2004.
- CalEPA Supplemental Guidance for Human Health Multimedia Risk Assessments of Hazardous Waste Sites and Permitted Facilities. August 1996.
- CalEPA Selecting Inorganic Constituents as Chemicals of Potential Concern at Risk Assessments at Hazardous Waste Sites and Permitted Facilities. Human and Ecological Risk Division Department of Toxic Substances Control. February 1997.
- CalEPA DTSC Preliminary Endangerment Assessment Guidance Manual (reprinted from 1994). January 1999.
- CalEPA DTSC Guidance for the Evaluation and Mitigation of Subsurface Vapor Intrusion to Indoor Air. 2005.
- USEPA User's Guide for Evaluating Subsurface Vapor Intrusion into Buildings. March 14, 2003.

- USEPA Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. OSWER 9355.4-24. 2002.

Additional USEPA and CalEPA documents and databases consulted for this HHRA are cited in the text and listed in Section 8.

1.2 USEPA Consent Decree

This HHRA has been prepared in accordance with Task 2 of the Statement of Work in Consent Decree No. 00-12471 between the United States Environmental Protection Agency (USEPA) and the Omega Chemical Site PRP Organized Group (OPOG). The Consent Decree was lodged on November 24, 2000 and entered into the US District Court on February 28, 2001.

Task 2 requires OPOG to "Implement a Vadose Zone Remedial Investigation/ Feasibility Study (RI/FS) For Contaminant Releases On, At, or Emanating From The Omega Property". The Site location and vicinity are illustrated on Figure 1-1. The figure also illustrates the Phase 1a area, where a groundwater remedy is currently being implemented in accordance with Task 1 of the Consent Decree. The groundwater remedy is expected to be operational in mid-2007.

1.3 Site History

The following section is a summary of information regarding previous owners, operations, and known historical chemical use at and in the vicinity of the Site.

1.3.1 Owners and Operators

The subject Site located at 12504/12512 East Whittier Boulevard was first developed in 1951. The Site occupies Los Angeles County Assessor Tract No. 13486, Lots 3 and 4. The Site is approximately 41,000 square feet (~0.94 acres) in area (200 feet wide x 205 feet long) and contains two structures - an approximate 140 by 50 foot warehouse and an approximate 80 by 30 foot administrative building. A loading dock is also attached to the rear of the warehouse. The exterior areas are concrete-paved and the Site is secured with a perimeter fence and locking gate.

Prior to initial construction of buildings in July 1951, the Site was used for agriculture; apparently the site has never been used for residential purposes. The Site was operated by Sierra Bullets prior to 1963. During operation of the Sierra Bullet facility, a 500-gallon underground storage tank (UST) was utilized for storage of kerosene. The UST was subsequently removed in 1987 by Fred R. Rippey, Inc.

From 1976 to 1991 Omega Chemical Corporation operated a treatment and disposal facility for commercial and industrial solid and liquid wastes and a transfer station for storage and consolidation of wastes for shipment to other treatment and/or disposal facilities.

Van Owen Holdings LLC of Los Angeles, California purchased the property in 2003. Star City Auto Body occupies the warehouse (12504 Whittier Blvd.) and performs auto body repair and painting on the premises. The auto body shop also leases the small paved parking lot north of the warehouse building for automobile parking. The former paved parking lot north of the warehouse building for automobile parking. The former administrative building (12512 Whittier Blvd.) and larger paved parking area south of the warehouse have had a variety of tenants since 2003. The former administration building is currently unoccupied, and the parking lot is used for temporary storage of wooden pallets by L&M Pallets on a month-to-month lease basis.

1.3.2 Facility Processes and Chemical Usage

Limited information regarding volumes and types of wastes handled by the Omega Chemical Corporation is available for review. According to the Phase II Close Out Report (Hargis and Associates, England and Associates, October 1, 1996), Omega Chemical Corporation operated the facility for recycling and treatment of spent solvents and refrigerants. Drums and bulk loads of waste solvents and chemicals (primarily chlorinated hydrocarbons and chlorofluorocarbons) from various industrial activities were processed to form commercial products which were returned to generators or sold in the marketplace. An Operation Plan, prepared by Omega Chemical Corporation in 1990 for proposed expansion of the facility, provided a summary of current and proposed facility processes, tank capacities, incoming and facility-generated waste stream characteristics and handling practices, etc.

The majority of the 11 treatment units were located in the general area of the warehouse loading dock. As indicated in the Operation Plan, a total of 27 storage tanks with a combined storage capacity of 109,400 gallons were present at the facility in 1990. Six large, vertical storage tanks were arranged in an L-shaped pattern in the southern corner of the Site. Five process tanks were located in the northern yard, and were arranged in a linear pattern along the side of the warehouse. The locations of the smaller storage tanks were not indicated in the Operation Plan.

Wastes accepted by Omega Chemical Corporation for recycling were broadly characterized as organic solvents and chemicals, and aqueous wastes with organic waste constituents. Sources of the incoming waste were a wide assortment of manufacturing and industrial processes (petroleum refining, rubber and plastics, chemicals, paper and allied products, furniture and fixture products, lumber and wood products, printing and publishing, textile mill products, food and kindred products, etc.).

The treatment and transfer activities at Omega resulted in releases of chemicals to soil, soil gas, and groundwater at the Site, as evidenced by the results of previous site investigations (the first conducted in 1985 by LeRoy and Crandall Associates regarding subsurface contamination at the tank farm). A removal action was performed at Terra Pave to address lead contamination in soil. It is possible that lead in airborne particulates from Terra Pave were deposited onto surface soils at the Site.

The principal VOCs detected in the soil gas at the Omega site and at the highest concentrations were Freon 113, Freon 11, 1,1,1-TCA and PCE. The most prevalent contaminants detected in soil and groundwater are volatile organic compounds (VOCs), primarily tetrachloroethylene (PCE) and related compounds, trichloroethene (TCE), and freons. Chlorinated methane compounds, including methylene chloride and chloroform, as well as acetone and toluene, are also detected at the downgradient Site boundary and off-Site. No indications of dense non-aqueous phase liquids (DNAPLs) were identified in vadose zone soil; although some groundwater concentrations are indicative of either non-aqueous phase liquids (NAPL) or residual saturation of VOCs within or above the capillary fringe.

Material found within the loading dock sump contained the high concentrations of VOCs. The Phase 2 Close Out Report (England & Associates, Hargis + Associates, Inc., October 1, 1996) included a plan (Technical Memorandum No. 5 [TM5], February 22, 1996) for removal and disposal of contaminated soils found inside a sump located on the elevated loading dock area. Soil gas sample SG10R was collected at a depth of 6 feet from the soils contained within this sump during November 1995. TM5 and a subsequent addendum in response to EPA comments (TM5A, June 26, 1996) indicated that the sump dimensions were 6 feet x 6 feet, the total probed depth was 6 feet, and the sump was concrete-lined on all sides. TM5a indicated that the contaminated soil would be removed in July 1996 following EPA approval of the TM. Documentation of the proposed removal action was not provided in the Close Out Report. Very high concentrations of the following compounds were detected in the SG10R sample: Freon 11 (38,428,000 ppb/v), Freon 12 (8,536,000 ppb/v), Freon 113 (107,577,000 ppb/v), PCE (104,000 ppb/v), and 1,1,1-TCA (16,012,000 ppb/v). By comparison, the following significantly lower concentrations were detected at nearby RI soil gas sample location VP007 at a depth of 6 feet: Freon 11 (8,800 ppb/v), Freon 12 (not detected at a detection limit of 78 ppb/v), Freon 113 (31,000 ppb/v), PCE (65,000 ppb/v), and 1,1,1-TCA (32,000 ppb/v). It is presumed that all loading dock sump material was excavated, transported to an USEPA-approved off-Site disposal facility, incinerated, and disposed.

In August 2000, two concrete-lined sumps located in the loading dock area were drained of accumulated rainwater, and the sumps were pressure-washed and backfilled with concrete slurry. The drained fluids were transported to Demenno/Kerdoon for disposal. One of the loading dock sumps measured 6 feet by 6 feet by 6 feet. Based on the dimensions of the concrete-lined sump and its location in the loading dock, it was assumed to be the former soil-filled sump. Because the sump was concrete-lined on all sides, the SG10R soil gas sample collected from within the sump is not considered to be representative of concentrations in Site soils and has not been included in the risk assessment calculations. No other exposed or near-surface grossly contaminated materials were identified.

1.4 Potential Risk Issues

This HHRA addresses potential risks and hazards associated with residual soil contamination at the site. The HHRA evaluates the current and future use of the site for commercial purposes. Risk issues at the Site may include partitioning of volatile organic compounds (VOCs) from the soil matrix into soil gas and subsequently into ambient² and indoor air. Because VOCs may accumulate to some extent indoors, inhalation of indoor air was quantitatively evaluated in the HHRA using measured indoor air vapor concentrations for current industrial workers. In addition to the Omega Site, potential for vapor intrusion was evaluated by building using indoor air data at the following areas:

- the parcel immediately to the north currently occupied by Medlin & Sons,
- the parcel immediately to the west currently occupied by TerraPave,
- the parcel to the south and west of the site (currently the occupied by the Bishop Company), and
- the parcel south of Bishop Company currently occupied by LA Carts and Oncology Care.

Minimum and maximum building concentrations were both evaluated to provide a potential range of risks and hazards. Measured concentrations of VOCs in indoor air from the parcel immediately to the south of the site (former location of the Skateland facility) were not included in the analysis since demolition of this building was completed on April 4, 2007. Because measured indoor air concentrations in current buildings may not represent future indoor air concentrations, indoor air exposure concentrations for future industrial workers and hypothetical residential receptors were evaluated using soil gas data modeled in a spreadsheet model to estimate indoor air concentrations.

Inhalation of ambient air was evaluated for current industrial workers using measured ambient air concentrations. However, because measured ambient air concentrations may not represent future ambient air concentrations, ambient air exposure for construction workers, industrial workers, and residents were estimated by modeling soil gas concentrations. Measured ambient air data were also compared to these modeled values in the uncertainties section.

In addition, construction workers at the Site may also be in direct contact with contaminated subsurface soil through incidental ingestion or dermal contact. These scenarios are evaluated in the HHRA for soil. The HHRA did not address these

² Throughout the text, tables, and appendices of this report, "ambient air" is defined to be "outdoor air." The two terms are used interchangeably throughout this report.

scenarios for soil at the above defined separate parcels. Soil sampling locations were concentrated on and along the border of the Omega site.

Currently, groundwater underlying the Site and in the immediate vicinity is not used for any purpose. Use for potable purposes within this area is also unlikely for the future due to the presence of high concentrations of total dissolved solids (TDS). As shown in Table 1-1, TDS concentrations in groundwater samples from 2004 to 2006 ranged from 630 to 1,700 milligrams per liter (mg/L). The USEPA secondary standard for TDS in drinking water is 500 mg/L while the CalEPA maximum contaminant level (MCL) for drinking water ranges from 500 mg/L (recommended) to 1,000 mg/L (upper) with a short-term concentration of 1,500 mg/L. Use of groundwater at and downgradient of the site will be addressed in a separate report, and is not included in this risk assessment.

Currently, no plans exist for residential development at the Site, and the Site location suggests that residential development in areas adjacent to the Site is unlikely. The City intends to allow redevelopment that consists of commercial and retail uses with the construction of multi-level buildings. Specifically, City representatives have stated that it is unlikely that the Omega property will be redeveloped for residential uses (Adams, 2007), although the zoning of the site as the Whittier Boulevard Specific Plan-Workplace District allows for Live/Work units and multi-family housing. Therefore, although residential use of the site is not expected to occur in the future, quantitative analysis of future residential exposures is provided to provide additional information to the risk manager. Section 4 provides a more detailed discussion of current and reasonable future land uses of the site.

1.5 Overview of Risk Assessment Findings

Results of the risk assessment suggest that contaminated soils at the site could present a significant threat to current and future commercial/industrial workers, future construction workers, and hypothetical future residents. Cancer risk estimates ranged from $4E-7$ to greater than the upper end of the USEPA risk range of $1E-4$. Hazard indices slightly exceeded one for current commercial/industrial workers at parcels other than the Site Parcel and were greater than one for future commercial/industrial workers, future construction workers, and future residents. Exposures to soil are unlikely under current conditions because of cover of most of the site with hardscape (buildings, concrete, and asphalt). However, future development could result in the removal of existing hardscape resulting in completed exposure pathways for future receptors. Risks and hazards are primarily attributable to inhalation of indoor air for current and future commercial/industrial indoor workers and future residents and ambient air for future outdoor commercial/industrial workers.

Possible risks associated with exposure to vapors intruding into indoor air spaces for current commercial/industrial workers are typically in the upper half of EPA's target

risk range of $1E-6$ to $1E-4$ ($9E-6$ to $1E-4$). HI estimates associated with current exposure for vapors intruding into indoor air spaces fell in the range of less than one to about 7.7. Possible risks associated with exposure to vapors intruding into indoor air spaces for future commercial/industrial workers are typically in the upper half of EPA's target risk range $8E-7$ to $5E-4$. HI estimates for vapors intruding into indoor air spaces for these receptors fell in the range of less than one to about 7. Risks associated with exposure to vapors intruding into indoor air spaces were highest for hypothetical future residents with risks ranging from $1E-6$ to $5E-3$, above EPA's target risk range. HI estimates for vapors intruding into indoor air spaces for these residents ranged from less than one to 108.

Risks and hazards were estimated for the Omega site and for surrounding parcels. VOCs in ambient air, as measured at the site, may account for 10 to 50 percent of these risks depending on the parcel.

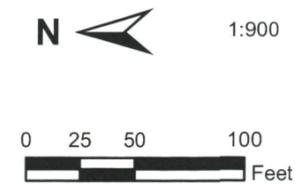

The basis for these risk estimates is provided in detail in the remainder of this report.

1.6 Report Organization

Following a brief description of the site geology and hydrology in Section 2, this HHRA was conducted in four phases as defined in Cal EPA and U.S. EPA guidance, including:

- Identification of chemicals of potential concern (COPCs) that exist in sufficient quantities to present a public health risk (Hazard Identification, Section 3)
- Analysis of ways in which people might be exposed to COPCs (Exposure Assessment, Section 4)
- Evaluation of the toxicity of COPCs that may present public health risks (Toxicity Assessment, Section 5)
- Characterization of the magnitude and location of potential health risks for the exposed community (Risk Characterization, Section 6)

Uncertainties, summary and conclusions, and references are provided in Sections 7, 8, and 9, respectively. Risk calculations are provided in Appendix A.

Section 2

Section 2

Physical Setting

A detailed description of the physical setting of the site including boring logs and cross-sections is provided in Section 2.4 of the pre-final On-Site Soils RI Report (CDM, 2007). This section provides a summary of the local geology and hydrogeology of the site.

2.1 Climate

The climate of the area is characterized as semi-arid, with an average annual precipitation of approximately 16 inches. Precipitation occurs mainly during the winter and spring months.

2.2 Surface Topography

The land surface at the former Omega Chemical property slopes to the southwest to south-southwest at approximately 0.016 feet per foot, and is situated at approximately 220 feet above mean sea level (msl).

2.3 Local Geology and Hydrogeology

In the vicinity of the former Omega Chemical property, groundwater is typically encountered between 70 and 80 feet bgs, and flows to the southwest. Table 2-1 summarizes water levels recorded in the Omega vicinity between 2001 and 2006. Well locations are shown on Figure 2-1.

Regional hydrogeologic information is inconclusive on the presence or absence of major regional named aquifers in this portion of the Whittier Area. A cross-section about 1.5 miles south of the former Omega Chemical property presented in Bulletin 104 (DWR, 1961) suggests that the uppermost aquifers present are the Gage and Jefferson Aquifers. The upper portion of the shallow aquifer may represent the Gage aquifer, while the lower aquifer is potentially the Hollydale or Jefferson aquifer. The Gage aquifer is the major water bearing member of the Lakewood formation in the Whittier area, where it consists of about 30 feet of sand with some interbedded clay. It can attain maximum depths of 150 feet. The Jefferson aquifer is part of the Lower Pleistocene San Pedro formation that underlies the entire Whittier Area. The formation is composed of sand and gravel with interbedded clay, likely of marine origin. It ranges in thickness from 20 to 40 feet and reaches a maximum depth of 350 feet.

Below the Gage and Jefferson aquifers are deeper members of the Lower Pleistocene San Pedro formation. From shallowest to deepest, they are the Hollydale, Lynwood, Silverado, and Sunnyside aquifers. The Hollydale aquifer may be located beneath the Site, as the Site is located in the western part of the Whittier Area. It ranges in thickness from 10 to 25 feet and reaches to a maximum depth of 100 feet, and merges with the overlying Gage near South Whittier. The Lynwood aquifer ranges in

thickness from 50 to 100 feet and extends to a maximum depth of 460 feet; the Silverado aquifer ranges in thickness from 110 to 300 feet, and extends to a depth of 750 feet; while the Sunnyside aquifer consists of 200 to 300 feet of sand and gravel and reaches a depth of 1,000 feet.

2.3.1 Vadose Zone

The vadose zone is generally comprised of clayey silts with occasional sand lenses. The shallower interbedded silty clays and clays are characterized by alternating layers of high and low soil conductivity materials. An important lithologic layer starting at an approximate depth of 30 feet bgs (hereinafter referred to as the 30-foot unit) was found dipping to the west and southwest. The 30-foot unit has a characteristic double peak signature on the MIP conductivity logs, with a lower conductivity interbed in the middle of the unit likely consisting of siltier materials. Nearly all borings show a 1- to 4-foot thick unit with lower conductance, interpreted to be a sandy to silty lithology with less clay overlying the marker bed. The "30-foot zone" itself is between 3.5 to 11 feet thick. The top of the zone slopes generally to the west-southwest with a southwesterly trough directly beneath the center of the Site.

2.3.2 Saturated Zone

Groundwater investigations performed to date have indicated the presence of the two aquifer zones present at the Site, separated by a low permeability confining zone. The first sandy zone is encountered near the first occurrence of groundwater. It originates a short distance southwest of the former Omega Chemical property and thickens dramatically to the west. MIP borings and soil borings advanced at the former Omega Chemical property indicate that the sandy unit does not exist beneath the former Omega Chemical property. The sandy unit was observed in borings along Putnam Street (west of the former Omega Chemical property) and is up to 35 feet thick at downgradient well OW-4/4B. In the MIP borings at the western edge of the former Omega Chemical property, the sandy zone is characterized by low conductivity between 45 and 60 feet bgs. The unit is characterized by fine to medium sands.

The shallow unconfined aquifer may also thin toward the north along Putnam Street, which is perpendicular to the general flow direction. The shallow aquifer configuration shows the presence of a lower permeability zone splitting the upper aquifer north of PZ1. The uppermost sand unit within the upper aquifer appears continuous below the water table elevation from H-7 at the northern end to EW-5 at the southern end of the section.

Based on water levels at the OW4 and OW8 locations, where both deep and shallow zone completions are available, the groundwater elevations are significantly higher in the shallow aquifer. A similar difference in water level, with an indicated downward gradient, was observed at the cluster at OW1/1b. This indicates that a significant confining zone limits flow between these zones.

Similar to the shallower unconfined aquifer, the deeper confined aquifer may also thin under the former Omega Chemical property and thicken to the west. Only the

deeper wells to the west penetrate into this unit; it was not observed at well OW-1B at Terra Pave. The deeper confined aquifer is characterized by sand with some silt.

2.3.3 Groundwater Flow and Aquifer Characteristics

Groundwater flow in the upper aquifer has been consistently towards the southwest based on depth to water and groundwater elevation data collected and contour maps prepared since mid-2001. Numerous aquifer tests have been performed on Omega wells over the past 7 years, as follows: slug tests and step-drawdown testing on wells OW-1b, OW-2, and OW-3 in 1999; short-term (approximately 4 hours) constant discharge testing on wells OW-2, OW-3, OW4a, and OW8 in 2003; and more recently approximately 24-hours of constant discharge testing performed in September 2006 on five wells installed in mid-2006 (EW-1 through EW-5) that are proposed for groundwater extraction as part of the Phase 1a area groundwater remedy. A technical memorandum detailing testing procedures and an evaluation of the testing results was prepared and submitted to USEPA in late-2006 (CDM, November 7, 2006).

Section 3

Data Analysis and Identification of Chemicals of Potential Concern

This section presents a summary of data available for the HHRA, a summary of the data evaluation, and the selection of preliminary Chemicals of Potential Concern (COPCs). Chemicals selected as COPCs were evaluated quantitatively. Data used in the HHRA were obtained from recent sampling events conducted by CDM and include soil, soil gas, and indoor and ambient air samples. As previously discussed, groundwater underlying the Site and in the immediate vicinity is currently not used for any purpose nor is it likely to be used for potable use in the future due to high concentrations of TDS. Further, a groundwater remedy is expected to be operational in mid-2007. Groundwater exposure pathways are not directly evaluated in this risk assessment. However, any groundwater vapor off-gassing was considered by the direct collection of indoor air samples or, in the case of the former Skateland parcel, measured concentrations of VOCs in soil gas..

A preliminary data evaluation was performed to determine the usability of existing data for the HHRA. Selection of data used to support quantitative evaluation is based on quality, quantity, comparability (e.g., similar detection limits), and representativeness of data for current site conditions and potential exposures at the site. During data evaluation, a set of data appropriate for use in qualitative and quantitative risk assessment is compiled. These data are then used in selection of COPCs and in estimation of exposure point concentrations used in the calculation of possible chronic daily intake. A more extensive discussion of data quality is provided in the pre-final On-Site Soils RI Report, which was submitted on June 20, 2007 (CDM, 2007).

3.1 Data to Support Human Health Risk Assessment

During the RI, samples were collected from surface soils, subsurface soils, soil gas, indoor air, and ambient air. Sample locations are shown in Figures 3-1 and 3-1b and analytical summary tables for all samples collected during the RI are provided in the RI report. Please refer to the tables and text provided in the RI report for a summary of analytical results. Sampling objectives, rationale, methodology, and locations are described in Section 3 of the RI report.

Approximately 208 soil samples of which 8 were duplicates were collected during roughly 13 sampling events from 1995 to 2006. Soil samples were collected at approximately 66 locations at depths up to 120 feet below ground surface (bgs). Soil samples were analyzed for a comprehensive suite of analyses including VOCs, SVOCs, metals and pesticides. Although historic soil samples (samples collected in 1995 to 1999) were included in the analysis, historic soil results for VOCs were not included because current soil, soil gas and indoor air samples are likely more representative of current conditions for VOCs at the site.

In addition, during the implementation of Task 1 of the Consent Decree, approximately 298 groundwater samples of which 34 were duplicates were collected during roughly 32 sampling events from 1996 to 2006. Groundwater samples were analyzed for a comprehensive suite of analytes including VOCs, SVOCs, and metals. Only data from groundwater samples collected from October 2004 to September 2006 are used in the qualitative risk analysis. Although groundwater samples were collected as early as 1996, these earlier samples cannot be assumed to be representative of current conditions.

Soil gas samples were collected from a total of 97 locations at depths up to 71 feet bgs. Seven sampling events occurred from 2004 to 2006, and a total of 271 samples (of which 31 were duplicates) were collected. Soil gas samples were collected in Summa canisters and analyzed by an off-site laboratory for VOCs using EPA Method TO-15.

Historical soil gas sampling results were not included because evaluation of the historical soil gas sampling results provided in the Phase II Close Out Report (Hargis + Associates, Inc. and England & Associates, October, 1996) indicated several potential deficiencies with the data, as follows: a notation on the analytical results summary table provided in the document indicated that the soil gas results were "preliminary", copies of the analytical reports were not provided and so were not available for review, and the mobile laboratory used was not identified nor were analytical quality assurance/quality control procedures discussed. In addition, non-detections for all tested VOCs were reported for seven samples (SG1 at 6 and 12 feet, SG4 at 16.7 feet, SG8 at 6 feet, SG15 at 6 and 12 feet, and SG31 at 3.5 feet). Though detection limits were higher in 1996 than during the RI, these non-detections are suspect given the elevated concentrations found throughout the Omega property during the RI. Therefore, the historical pre-RI soil gas results were not included in the risk analysis. Historical sampling locations are shown on Figure 3-2. As shown on Figure 3-1 and 3-1b, a sufficient number of soil gas samples were collected during the RI to perform the risk analysis provided in this document.

2004 to 2006 soil gas data were used for quantitative risk analysis for future scenarios (hypothetical residential scenario and future construction scenario) on the site and most surrounding parcels. These data were also used to estimate a range of attenuation factors to assist in evaluation of a future commercial/industrial land use scenario.

Sixty-eight indoor air samples (of which 11 are duplicates) were collected from 25 locations during seven sampling events from 2004 to 2006. Thirteen ambient air samples (including one duplicate) were collected from nine locations during four of these sampling events. Air samples were collected in Summa canisters and analyzed by an off-site laboratory for VOCs using EPA Method TO-15, TO-15 SIM, or TO-14.

In conjunction with the soil vapor survey, soil conductivity profiling was performed during the RI using the Membrane Interface Probe (MIP) system. Evaluation of the soil conductivity and lithologic logs indicated the presence of a continuous finer-

grained unit underlying the Site and adjacent areas at an approximate depth of 30 feet bgs. This unit is identified in the RI report as the "30-foot unit". The 30-foot unit likely inhibits the vertical migration of contaminants from moving to greater depths. This unit is described at length in the RI report.

The protocol used and data generated from all of the sampling efforts are discussed in detail in the RI Report.

3.2 Data Evaluation

Chemical data were reviewed to determine overall usability, for assessing potential human health risks. Data were evaluated to assess precision, accuracy, representativeness, completeness, comparability (PARCC parameters) and sensitivity (blanks). Analytical results for data and details of the data quality assessment are presented in the RI Report. This assessment also includes a review of appropriateness of the reporting limits for risk assessment purposes. Data were found to be of high quality and are considered useable for risk assessment purposes.

Data representativeness is one of the most important criteria evaluated when selecting data for use in the quantitative HHRA. Representativeness is the extent to which available data characterize potential exposure conditions for human or ecological receptors. Proper selection of sampling locations, consideration of potential hot spots, assessment of background concentrations, and collection of a sufficient number of samples help maximize data representativeness. The RI data were collected in contaminated or potentially contaminated areas and in areas where human contact is possible either currently or in the future.

Soil samples were collected throughout the Omega parcel and from variable depths, providing extensive documentation of the nature and extent of contamination at the site. Sampling was somewhat biased toward areas of known or suspected releases, so that the database as a whole is likely to be somewhat biased toward higher levels of contamination. Any such bias should result in overestimation of potential risks. Soil samples were not collected from surrounding parcels. Concentrations of chemicals in site soil were considered a worst-case for site-related off site contamination.

Indoor air samples were collected in one to several rounds, depending on the parcel as defined in Section 1. Multiple rounds of indoor air sampling help to minimize impact of any seasonal impacts. Moreover, several indoor air samples were collected in each building, from different areas. Multiple samples within a building help to minimize impacts of ventilation on VOC concentrations and help determine if and where building sources (e.g. consumer products) may impact results. Indoor air samples can be characterized as reasonably representative of indoor air quality in buildings on and around the site. Indoor air data may also reflect building sources rather than or in addition to vapors intruding from the subsurface. Thus, indoor air

data may be biased by building sources unrelated to VOCs previously released at the Omega site.

3.3 Identification of Chemicals of Potential Concern

General methods for selection of COPCs followed basic USEPA and CalEPA policy of initially including chemicals observed at the site, regardless of potential for human health risk, and putting any risks due to exposure to chemicals at the site in perspective during the risk characterization. In keeping with this policy, all chemicals detected in media at the site were retained as COPCs, with the following few exceptions:

- Inorganic soil constituents that are essential minerals and/or are present only at concentrations consistent with local ambient conditions were eliminated.
- Chemicals detected with a frequency of less than 5 percent, provided that other criteria as described below were met, were eliminated.
- Chemicals without available toxicity criteria were not retained as COPCs.

The tables listing detected chemicals and their summary statistics provided in this section are the same as the RAGS Part D tables in Appendix A-3, Tables 2.1 through 2.6, as available. RAGS Part D tables were not created for media that were not identified as complete exposure pathways (e.g. groundwater), so tables summarizing these media have a different format. A summary of the selection of COPCs is described in text in the following sections.

3.3.1 Non-Toxic and Essential Minerals

Several metals that are generally recognized as non-toxic and are essential minerals will not be addressed in the risk assessment. Eliminated chemicals include calcium, sodium, potassium, magnesium, chloride, fluoride, nitrate, and nitrite. Nitrate and nitrite do not have screening criteria for soil and will not be COPCs for soil. Water concentrations are far below levels of concern, and potential exposure via drinking water is not evaluated in this HHRA. Since these constituents are not volatile, no potential exposure pathways exist and these chemicals will not be quantitatively evaluated. Fluoride does have soil screening criteria, but no soil data are available for fluoride. This chemical is also nonvolatile. Since groundwater exposure is not evaluated, fluoride also will not be quantitatively evaluated.

Some essential minerals, such as iron and manganese, were not eliminated in this step. Such metals, though essential, can be associated with adverse effects and were retained unless eliminated in subsequent COPC selection steps.

3.3.2 Analysis of Ambient Concentrations of Arsenic

Local ambient concentrations of arsenic in soil were assessed using guidance developed by the Department of Toxic Substances Control (DTSC) for selection of

inorganic constituents as chemicals of concern (DTSC 1997). For this analysis, soil data for the site are combined into a single data set and plotted on a normal probability plot. Typically, both untransformed and lognormally transformed data are plotted, because the distribution of environmental data often approximates lognormal. These plots and summary data statistics are then evaluated. Where one of the normal probability plots approximates a straight line, the total data range is about an order of magnitude or less, and the coefficient of variation is less than one (i.e., data variability is low), the data are likely to be part of a single, local ambient distribution. Where normal probability plots are clearly non-linear and show one or more "inflection points", more than one population is likely to be present, and only those data that fulfill the above criteria can be considered to represent local ambient conditions. Typically, when inflection points are identified in the plots, data range is greater than an order magnitude, and the coefficient of variation is greater than one and often much higher.

The probability plot of the arsenic soil data from the Omega site is a straight line suggesting a single population of arsenic concentrations. These data likely represent local ambient conditions, not arsenic releases from the site. This conclusion is bolstered by the relatively small data range (0.8 to 21 mg/kg), and the small coefficient of variation (about 0.65). The highest value of 21 mg/kg is over twice as high as the next highest arsenic concentration of less than 10 mg/kg. The distribution of sample locations (as presented in the RI) indicates substantial coverage of the Omega site (41 samples distributed over less than one acre) suggesting that the single higher value does not represent a substantial hotspot. This observation is consistent with the location of the single higher value at the northeast corner of the site parcel. Operations are not known to have been carried out in this location.

Evaluation of arsenic soil data for the site indicates that arsenic is present at local ambient levels. The single higher value in the data set is most likely a data artifact. Data are sufficiently robust to eliminate the possibility that this single value represents a significant hotspot at the site. On this basis, arsenic was eliminated as a COPC at the site. Results of the statistical analysis are provided in Appendix B.

3.3.3 Frequency of Detection

Chemicals that are detected very infrequently at a site are not likely, with few exceptions, to contribute significantly to overall risk. Many chemicals reported in samples collected from soils at the site were in fewer than 5 percent of samples. These chemicals may not represent a significant release at the site, and may not, in some cases, be site-related. Thus, elimination of these chemicals makes the risk assessment much less cumbersome and much more focused on significant releases at the site. However, prior to eliminating infrequently detected chemicals, several criteria must be met as described below.

Infrequently detected chemicals were not eliminated if they were: 1) known human carcinogens; 2) were detected at very high concentrations compared to minimum levels that could be associated with adverse effects (e.g. OEHHA soil California

Human Health Screening Levels [CHHSLs], 2005b); and/or 3) were found at the site in localized "hotspots." Hotspots are defined as relatively small areas with chemical concentrations that are significantly higher than those in surrounding areas. In most, but not all, cases, hotspots correlate with source areas.

Chemicals that were infrequently detected and do not fall into any of the above categories were eliminated from the quantitative assessment. Chemicals eliminated include:

- Benzyl alcohol, benzo(g,h,i)perylene, diethylphthalate, di-n-butylphthalate, di-n-octylphthalate, and endrin in soil, 0 to 2.2 feet bgs
- Acetone, benzo(g,h,i)perylene, and cis-1,2-dichloroethene in soil, 0 to 12 feet bgs
- 1,2-Dichlorobenzene, 1,4-dichlorobenzene, acetone, benzo(g,h,i)perylene, bromoform, cis-1,2-dichloroethene (cis-1,2-DCE), diethylphthalate, di-n-butylphthalate, di-n-octylphthalate, endrin, trans-1,3-dichloropropene, trans-1,2-dichloroethene (trans-1,2-DCE), total xylenes, and vinyl acetate in soil, 0 to 30 feet bgs
- 1,1,2-Trichloroethane, 2-butanone, n-hexane, and o-xylenes in all parcels and site parcel soil gas, 5 to 6 feet bgs
- 4-Ethyltoluene and 4-methyl-2-pentanone in all parcel soil gas, 5 to 30 feet bgs
- 1,2,4-Trimethylbenzene, 2-propanol, 4-Ethyltoluene, and ethanol in site parcel soil gas, 5 to 30 feet bgs
- 4-Methyl-2-pentanone in other parcels soil gas, 5 to 30 feet bgs
- 1,2,3-Trichloropropane; 1,2,4-trichlorobenzene; 4-chlorotoluene; carbon disulfide; fluorene; isophorone; pentachlorophenol (PCP); phenanthrene; and methyl acetate in groundwater

3.3.4 Chemicals without Toxicity Criteria

Toxicity criteria have not yet been established for all detected chemicals. Quantitative risks and hazards can not be calculated in the absence of these toxicity criteria. As such, these chemicals were removed from the quantitative analysis. Uncertainties regarding their removal are discussed in Section 6.4. The only chemical eliminated based on lack of toxicity criteria was:

- Benzo(g,h,i)perylene in soil for 0 to 2.2 feet bgs, 0 to 12 feet bgs, and 0 to 30 feet bgs

3.3.5 Selection of COPCs for Soil

Because some exposure pathways are limited to surface soil and others to subsurface soil, surface soil and subsurface soil were assessed separately. Surface soil includes

samples up to 2.2 feet bgs. Subsurface soil was divided into three categories – greater than 2.2 feet to 12 feet bgs, greater than 12 feet to 30 feet bgs and greater than 30 feet bgs. The 12-foot bgs limit was selected to represent the maximum depth to which a resident or a construction worker could be exposed following or during regrading at the site. Summary statistics for soil data are presented in Tables 3-1, 3-2, and 3-3. These tables show minimum and maximum concentrations, the range of reporting limits, and the detection frequency for detected constituents in soil. In Table 3-2, subsurface soil from greater than 2.2 to 12 feet bgs were combined with the surface soil data to create a soil data set that represents soil if the site were regraded, mixing surface soil with subsurface soil.

Samples from depths below 12 feet bgs (Table 3-3) were not used in the quantitative risk assessment; however, these samples were examined to help ensure that no constituents were being overlooked. Table 3-4 provides a comparison of the greater than 12 feet bgs data with the less than 12 feet bgs data. Chemicals in samples depths below 12 feet bgs that were detected at frequencies greater than 5% that were not included as COPCs in the 0 to 12 feet bgs data include: 1,1,2-trichloro-1,2,2-trifluoroethane, benzene, cis-1,2-DCE, methylene chloride, toluene, trans-1,2-DCE, and trichlorofluoromethane. However, none of the maximum detected concentrations of these chemicals exceeded one-tenth of the USEPA Region 9 PRG for residential soil. Therefore, none of these chemicals are likely to figure prominently in a risk assessment of the site. Thus, no additional COPCs were identified.

3.3.6 Selection of COPCs for Groundwater

Groundwater samples collected from October 2004 to September 2006 (the last two years) are considered to be more representative of current and future groundwater conditions than samples collected earlier. Summary statistics for groundwater data collected in 2004 through 2006 and presented in Table 3-5. This table shows minimum and maximum concentrations, the range of reporting limits, and the detection frequency for all detected constituents in groundwater. Similar statistics are also presented separately for data collected from 2001 to 2004 (Table 3-6). These statistics help show the variation in groundwater quality over time.

3.3.7 Selection of COPCs for Soil Gas

Soil gas samples were collected from depths of 2 feet bgs to 71 feet bgs in 1990, 1995, 1999, 2004, 2005, and 2006. Since the primary exposure pathway of concern is indoor air, only the more shallow gas samples, ~6 feet bgs, were used in the primary analysis. Because the site and surrounding parcels are almost completely paved, barometric pumping is not expected to be significant and soil gas collected at ~ 6 feet bgs soil gas is most appropriate for estimating indoor air concentrations. In addition, many soil gas samples were collected immediately adjacent to buildings to best characterize likely VOC concentrations beneath buildings.

The conclusion that shallow soil gas is representative for examining vapor intrusion is support by comparing concentrations from this depth interval with soil gas data from

the depth interval for 5 to 6 feet (Table 3-7a) to 30 feet bgs (Table 3-8a). In almost all cases, the highest maximum and median soil gas concentrations for PCE, TCE and Freon 113 are observed in the shallow interval. These chemicals were selected because they are obviously site related and occur at the highest concentrations observed at the site. Further, as reported in Section 5, risk characterization, PCE and TCE are responsible for the highest risks estimated for the site. The only exceptions were for TCE (but not PCE) for the South parcel, and for all chemicals in the West parcel - TerraPave. In no case were concentrations of PCE or TCE in the deep interval greatly higher than in the shallow. For example, shallow and deep soil gas concentrations for PCE in the west parcel-TerraPave were 1,600,000 and 1,800,000 $\mu\text{g}/\text{m}^3$, respectively for shallow and deeper soil gas. The largest difference was observed for Freon 113 in the west parcel-TerraPave, 500,000 versus 1,500,000 $\mu\text{g}/\text{m}^3$ for shallow and deeper soil gas respectively. Freon is not, however, an important risk driver for the site. Relative concentrations of the two more important risk drivers for this parcel are similar for both depth intervals. Overall, use of shallow soil gas for quantitative analyses in this risk assessment appears to be a reasonable approach.

Also, because soil gas concentrations are likely to change over time, only the more recent soil gas samples (2004 to 2006) are included in the analysis. Soil gas samples were collected April 2004, November 2004, August 2005, December 2005, March 2006, and May 2006. Soil vapor probes were installed using a direct push rig. Soil gas sampling and analysis were conducted in general accordance with the Advisory-Active Soil Gas Investigations dated January 28, 2003, jointly issued by the DTSC and the Los Angeles RWQCB (DTSC/LARWQCB Advisory). One-liter pre-cleaned and evacuated Summa [®] canisters provided by a California- certified analytical laboratory were used to collect all soil vapor samples. Summa canisters were evacuated to 30 inches of mercury vacuum and a flow regulator was placed between the probe and the canister to ensure that the canister was filled at the appropriate flow rate of 200 milliliters per minute (ml/min). Following collection, Summa canisters were labeled with a laboratory-provided sample tag, and shipped to an off-site, fixed base analytical laboratory with a completed chain-of-custody form. The collection of soil gas samples followed the procedures specified in the DTSC/ LARWQCB Advisory (2003), which recommends purging and leak testing to ensure sample integrity, as appropriate for field conditions. Isobutane was used as a leak check compound, and the laboratory reported isobutane as a Tentatively Identified Compound (TIC). Isobutane was not detected in any of the soil gas samples. Detailed descriptions of the soil vapor sampling events and sampling methodology are provided in Sections 3.1.3 and 3.3 of the RI report, respectively.

For the risk evaluation, soil gas data were divided into three categories:

- All Parcels - This category includes the Omega site parcel as well as the parcels to the north (Medlin & Sons), south (LA Carts and Oncology Care), south/west (Bishop Company), and west (TerraPave).

- Site Parcel - This category only includes the former Omega site parcel where Star City Auto Body and the Three Kings Construction are currently located.
- Other Parcels - This category includes the parcels to the north (Medlin & Sons), south (LA Carts and Oncology Care), south/west (Bishop Company), and west (TerraPave).

Tables 3-7a, 3-7b, and 3-7c summarize the 5 to 6-foot bgs data for All Parcels, Site Parcel, and Other Parcels. Tables 3-8a, 3-8b, and 3-8c summarize the 5 to 30-foot bgs data for All Parcels, Site Parcel, and Other Parcels. Since PCE and TCE are the primary chemicals of concern at the site, Figures 3-3 and 3-4 show soil vapor plumes depicting PCE and TCE soil gas CHHSL exceedances for samples collected from 0 to 6 feet bgs, respectively. Figures 3-5, 3-6, and 3-7 present soil vapor concentrations for samples collected 0 to 30 feet bgs for total VOCs, PCE, and TCE, respectively.

As noted in Section 3.1, historical soil gas data were determined to be of insufficient quality for the HHRA. Moreover, locations of more recent sampling not only suitably represented by more recently collected samples, the current data provide much more extensive characterization, especially in surrounding parcels. Thus, omission of these historical soil gas data is appropriate for this site. Please refer to the RI for further discussion of the historic soil gas data.

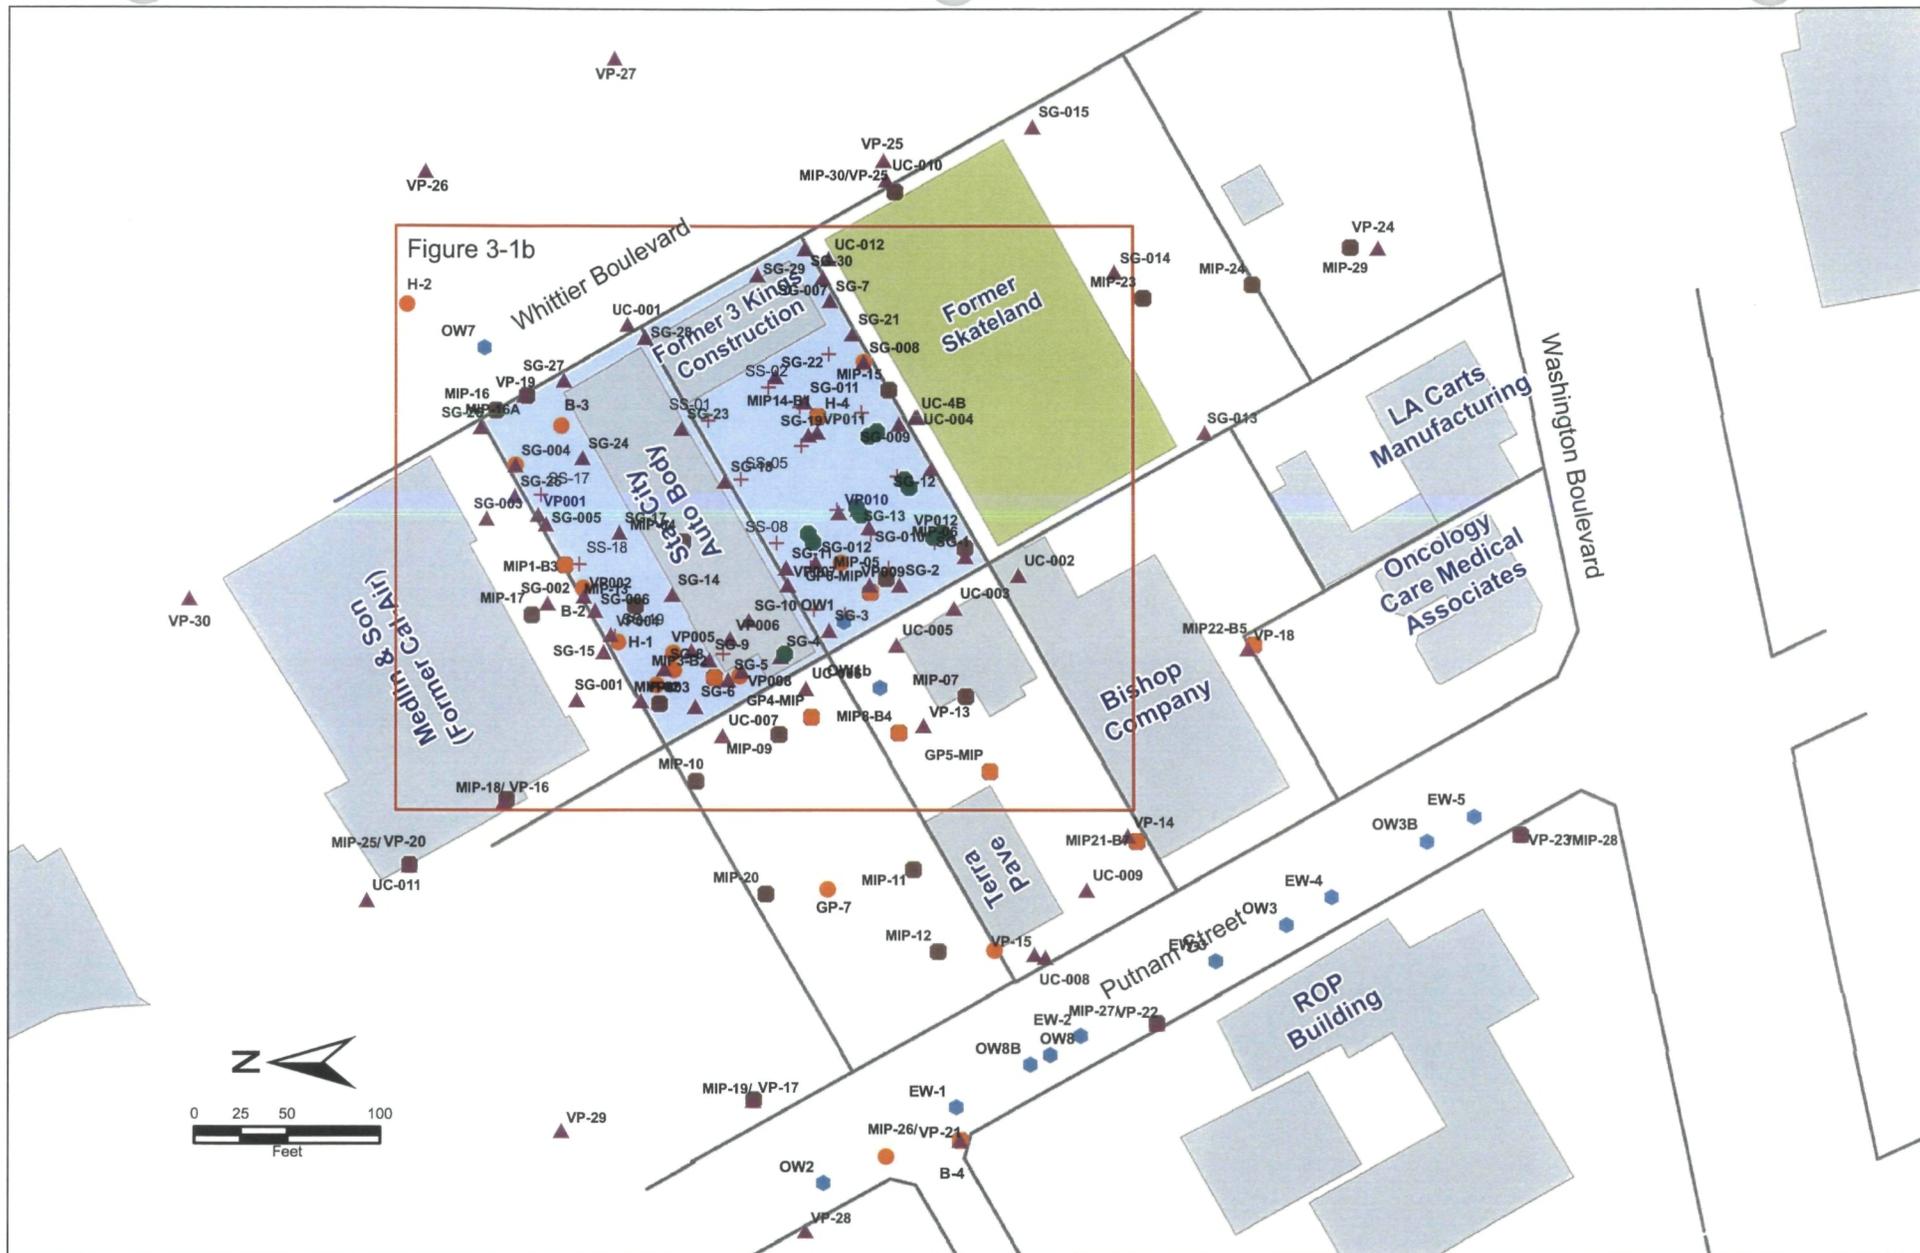

Measured indoor air data are used to evaluate all of the indoor air pathways for current scenarios for all of the buildings, except for the former Skateland facility because this building was demolished as of April 4, 2007. No houses currently exist onsite, therefore to estimate hypothetical future resident indoor air exposure, measured soil gas data ranging from 5 to 6-foot bgs for the Site Parcel and for Other Parcels summarized in Tables 3-7b and 3-7c were used in the J&E model to quantitatively evaluate this pathway for the hypothetical future resident and the future industrial worker. Measured soil gas data ranging from 5 to 30-foot bgs summarized in Tables 3-8a, 3-8b, and 3-8c were used in the J&E model to quantitatively evaluate the ambient air pathway for the construction scenario.

Because soil gas from deeper samples could in theory represent a source of VOCs at shallow depths, deeper soil gas samples, greater than 30 feet bgs, are presented in Table 3-9. These statistics help ensure that no detected constituent was overlooked in the shallower data. These deeper data were not used in the calculation of exposure point concentrations (Section 3.5).

3.3.8 Selection of COPCs for Indoor and Ambient Air

Indoor and ambient air samples were collected from May 2004 to September 2006. Sampling protocols, building surveys, and criteria used to choose indoor air sampling locations, and target analytes are described in the OSS RI Work Plan (CDM, 2003) and addenda (CDM 2004; 2005; 2006). Section 3.1.6 of the RI discusses locations and rationale for air sample locations. EPA reviewed and approved all sampling locations prior to sampling, and USEPA representatives were on-site during all indoor and

ambient air sampling events to oversee and document sampling procedures and collect split samples. Since indoor air data are evaluated separately by building, summaries of indoor air data by building are provided in Tables 3-10 through 3-17. Indoor air samples were collected from Medlin & Sons North Building, Oncology Care, LA Carts, and Bishop in September 2006; from Terrapave, Star City Autobody, Three Kings Construction, and Medlin & Sons in May 2004 and September 2005. Ambient air data are summarized in Table 3-18. Measured ambient air concentrations were used quantitatively to calculate ambient air exposure.

	7440-62-2	VANADIUM	20	71	mg/kg	SB-05	40 / 40	10 - 10	71	NA	1.0E+02 nc			Yes	FD
	7440-66-6	ZINC	34	350	mg/kg	SB-12	40 / 40	0.001 - 0.085	350	NA	1.0E+04 max			Yes	FD

- (1) Detection limits for detected chemicals in historical data were not available.
- (2) Maximum detected concentration used for screening.
- (3) Maximum detected background concentration.
- (4) Screened against 1/10th EPA's Region 9 Preliminary Remediation Goals (PRGs) for Industrial soil (EPA 2004c) to account for additivity of multiple chemicals.
- (5) Not available.
- (6) Chromium concentrations were divided between Chromium III and Chromium VI assuming a 1:6 ratio of Cr VI:Cr III
- (7) Rationale Codes:

Definitions:

NA: Not Available.
 ND: Not Detected.
 nc: Screening Toxicity Value is based on noncancer effects.
 ca: Screening Toxicity Value is based on cancer effects.
 COPC: Chemical of Potential Concern.
 ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered
 VOCs: Volatile Organic Compounds.
 ug/kg: microgram per kilogram.
 ca*: where nc PRG < 100X ca PRG
 ca**: where nc PRG < 10X ca PRG

Selection Reason:

ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs

Deletion Reason:

NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 NTX1: Infrequent Detection and No Toxicity Information Available
 IFD: Infrequent Detection
 IFD1: Infrequent Detection and Below Screening Level
 STAT: Not a site contaminant according to separate statistical analysis, see text

- (1) Maximum detected concentration from onsite samples
 (2) Maximum detected background concentration
 (3) Screened against 1/10th EPA's Shallow Soil Gas Screening Levels for Human Health (Vapor Intrusion) for Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.
 (4) Rationale Codes:

Definitions: NA: Not Available.
 ND: Not Detected.
 nc: Screening Toxicity Value is based on noncancer effects.
 ca: Screening Toxicity Value is based on cancer effects.
 COPC: Chemical of Potential Concern.
 ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered
 ug/m³: microgram per cubic meter.

Selection Reason: ASL: Above Screening Level
 TOX Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs
 NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 IFD: Infrequent Detection

(1) Maximum detected concentration from onsite samples

(2) Maximum detected background concentration.

(3) Screened against 1/10th EPA's Shallow Soil Gas Screening Levels for Human Health (Vapor Intrusion) for Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.

(4) Rationale Codes:

Selection Reason: ASL: Above Screening Level

TOX: Chemical is a Class A Carcinogen

DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs

NSL: No Screening Level

FD: Frequent Detection

CARC: Infrequent Detection but Chemical is a Carcinogen

Deletion Reason: BSL: Below Screening Level

BSL1: Infrequent Detection and Below Screening Level

NUT: Essential Nutrient

NTX: No Toxicity Information Available

IFD: Infrequent Detection

Definitions:

NA: Not Available.

ND: Not Detected.

nc: Screening Toxicity Value is based on noncancer effects.

ca: Screening Toxicity Value is based on cancer effects.

COPC: Chemical of Potential Concern.

ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered

ug/m³: microgram per cubic meter.

(1) Maximum detected concentration from onsite samples

(2) Maximum detected background concentration.

(3) Screened against 1/10th EPA's Shallow Soil Gas Screening Levels for Human Health (Vapor Intrusion) for Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.

(4) Rationale Codes:

Selection Reason: ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs
 NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 IFD: Infrequent Detection

Definitions:

NA: Not Available.

ND: Not Detected.

nc: Screening Toxicity Value is based on noncancer effects.

ca: Screening Toxicity Value is based on cancer effects.

COPC: Chemical of Potential Concern.

ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered ug/m³ microgram per cubic meter.

- (1) Maximum detected concentration used for screening
 (2) Maximum detected background concentration.
 (3) Screened against 1/10th CalEPA's CHHSLs Indoor Air Screening Levels for Human Health Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals
 (4) Rationale Codes:

Definitions: NA: Not Available.
 ND: Not Detected.
 nc: Screening Toxicity Value is based on noncancer effects.
 ca: Screening Toxicity Value is based on cancer effects.
 COPC: Chemical of Potential Concern.
 ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered
 ug/m³: microgram per cubic meter.

Selection Reason ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs
 NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 IFD: Infrequent Detection

Section 4

Section 4

Exposure Assessment

Populations that may be exposed to contaminants at a site and pathways by which these populations may come into contact with site contaminants are identified in the exposure assessment. In addition, methods used to quantify potential exposures are presented. The goal of the exposure assessment is to estimate reasonable maximum exposure (RME) and central tendency exposure (CTE) for populations that may be exposed to chemicals at the site. RME typically falls within the 90th to 99.9th percentile of possible exposures (EPA, 1993b), and is designed to fall among the highest exposures that are reasonably expected to occur. Estimates for RME typically form the basis for remedial decisions. CTE is based on more typical human behavior patterns. Estimates of CTE are generally used to evaluate uncertainties and obtain insights into the range of exposures that may occur.

The remainder of this section discusses evaluation of RME and CTE for people that may use the site currently or in the future after redevelopment. This section is divided into several subsections, as follows:

- Exposure Assessment Process (Section 4.1)
- Site Setting (Section 4.2)
- Site Conceptual Exposure Model (SCEM) (Section 4.3)
- Exposure Parameter Assumptions (Section 4.4)
- Exposure Point Concentrations (Section 4.5)
- Chemical Intake Equations (Section 4.6)

4.1 Exposure Assessment Process

Exposure is defined as human contact with a chemical or physical agent (EPA, 1989). Exposure assessment is the estimation of magnitude, frequency, duration, and pathway(s) of exposure to a chemical. Assessment of exposure consists of three steps:

- Characterization of Exposure Setting
- Identification of Exposure Pathways
- Quantification of Exposure

The first step of the exposure assessment involves identifying physical characteristics of a site and the current and potential future use of the site by people. These characteristics, along with concentrations and distributions of COPCs, define the exposure setting for current and future human receptors.

Step two of the exposure assessment identifies pathways by which people might be exposed to site-related chemicals. Chemical sources, release and transport mechanisms, and inter-media transfer are evaluated. Exposure pathways are identified based on the location and activities of potentially exposed human receptors and on the types of potentially contaminated media.

The final step, exposure quantification, has two components: estimation of exposure point concentrations and calculation of chemical intake. Exposure point concentrations are chemical concentrations at the point of human contact with site media such as soil and soil gas. Site-specific chemical data from site investigations are used to estimate chemical exposure point concentrations. Summary statistics for available site data, exposure point concentrations, and equations for estimating these concentrations are presented in the HHRA.

Results of the exposure assessment are documented in RAGS Part D Tables A3-0 to A3-9.11, provided in Appendix A-3.

Chemical intake is the amount of chemical contacted per unit of body weight per unit of time, generally expressed as milligrams (mg) of chemical intake per kilogram (kg) body weight per day. Chemical intake is calculated by combining pathway-specific exposure assumptions, such as frequency and duration of exposure, with exposure point concentrations. Pathway-specific exposure assumptions are presented herein; chemical intake calculations are included in appendices to this document. Pathway-specific exposure assumptions used to calculate intake are based on site-specific data (when available) and USEPA and/or CalEPA default exposure assumptions.

4.2 Site Setting

Included in the characterization of the exposure setting is a description of physical characteristics of the site and identification of current and potential future human populations on and near the site as they pertain to potential human exposure.

As previously discussed, the Omega site is located in a commercial/industrial area in Whittier, California. From 1976 to 1991, Omega Chemical Corporation operated a treatment and disposal facility for commercial and industrial solid and liquid wastes and a transfer station for storage and consolidation of wastes for shipment to other treatment and/or disposal facilities. In 2003, Van Owen Holdings LLC of Los Angeles, California purchased the property. Currently, two buildings (an office building and a warehouse) are located at the relatively flat Site, with concrete paving covering exterior areas. Star City Auto Body occupies the warehouse (12504 Whittier Blvd.) and performs auto body repair and painting on the premises. The auto body shop also leases the small paved parking lot north of the warehouse building for automobile parking. The former administrative building (12512 Whittier Blvd.) and larger paved parking area south of the warehouse have had a variety of tenants since 2003. The former administration building is currently unoccupied, and the parking lot is used for temporary storage of wooden pallets by L&M Pallets on a month-to-month lease basis.

One commercial property (formerly Skateland) and two industrial properties (Medlin & Son and Terra Pave) are immediately adjacent to the Site (southeastern, northwestern, and southwestern boundaries, respectively). The northeastern boundary of the Site is bordered by Whittier Boulevard and a frontage road. The former Skateland facility, located at 12520 Whittier Boulevard, formerly had an indoor roller skating rink building that was demolished April 4, 2007. The Medlin & Son (former Cal-Air facility) facility, located at 12484 Whittier Boulevard, is operated as a machine shop (screw machines, lathes and mills, tapping and threading, saw cutting, welding, etc.).

The Terra Pave, Inc. facility, located at 12511 East Putnam Street, is utilized by a paving contractor. The property is utilized for temporary storage of asphalt paving materials for various job sites. Terra Pave also utilizes the property to park and maintain a variety of support vehicles and heavy-duty paving equipment. New England Lead Burning Company (NELCO), previously operated on the Terra Pave site in the mid-1950s. According to a Phase 1 Environmental Site Assessment (ESA) Report of the property prepared by Cardinal Environmental Consultants (Cardinal) on September 11, 1991, NELCO purchased lead in sheets, pipe and solid rods and fabricated the desired product by burning (welding) the lead to the required shape. NELCO subcontracted Vector Three Environmental Inc. of Brea, California, to clean the interior of all facilities and remove superficial lead from the topsoil. Remedial activities were monitored by Cardinal staff and confirmatory dust wipe and soil samples confirmed that remaining lead levels were very low. Environmental reports and sampling results were not available for review; therefore, lead levels prior to and after remediation and the depth of the soils removal are unknown.

Both current and future land use are evaluated in the selection of potential human receptors (EPA, 1991a). As described above, the Site is currently used for industrial purposes and will likely remain industrial or commercial in the future given the site surroundings of commercial/industrial use. The Site has never been used for residential purposes in the past, and given its zoning, it is unlikely that it will be used for residential purposes in the future. The City intends to allow redevelopment that consists of commercial and retail uses with the construction of multi-level buildings. Specifically, City representatives have stated that it is unlikely that the Omega property will be redeveloped for residential uses (Adams, 2007 – provided as Appendix C), although the zoning of the site as the Whittier Boulevard Specific Plan-Workplace District allows for Live/Work units and multi-family housing. Therefore, a residential scenario is included in the analysis to provide additional information to the risk manager.

During an August 2006 groundwater sampling event, groundwater underlying the Site was measured at a depth of approximately 75 feet below ground surface. A fine-grained unit exists starting at about 30 feet bgs. Currently, groundwater underlying the Site and in the immediate area is not used for domestic, industrial, or agricultural

purposes. The nearest active downgradient water supply wells are located more than one mile from the former Omega Chemical property. The closest active well (well 30R3) is located on Dice Road by Burke Street, approximately 1.25 miles downgradient of the former Omega Chemical property. This well is screened from 200 to 900 feet bgs and at least two aquitards appear to be present between the shallowest aquifer and the top of the well screen. Future use of groundwater for potable purposes is also unlikely due to high concentrations of TDS (Table 1-1). No evidence suggests that contamination extends to any potable aquifer that underlies the Gage unit.

4.3 Site Conceptual Exposure Model

The site conceptual exposure model (SCEM) presented in this HHRA is consistent with the final On-site Soils Remedial Investigation/Feasibility Study Work Plan dated September 29, 2003 and describes the potential exposure pathways associated with the site, including potential sources of contamination, transport mechanisms, exposure routes, and potentially exposed populations. An exposure scenario consists of a potentially exposed population and one or more exposure pathways by which the receptor population may contact contaminants associated with a site. Only exposure pathways likely to be complete and to contribute significantly to overall exposure are evaluated quantitatively in the HHRA.

A complete exposure pathway consists of the following four elements:

- A source and mechanism of release of chemicals to the environment
- A transport medium for the released chemical
- An exposure point (the point of potential contact between receptor and medium)
- An exposure route (e.g., inhalation, ingestion)

If one or more of these elements are missing, the pathway is incomplete. Incomplete pathways are not quantitatively evaluated. Potentially complete pathways that are unlikely to contribute significantly to overall exposure are also not quantitatively evaluated. Therefore, an analysis of exposure pathways is included to identify those complete and significant exposure pathways that may be important for risk management decisions.

Sources of contamination, mechanisms of contaminant release from sources, and subsequent transport of contaminants through the environment are examined in this section to identify potentially contaminated media at the site. Potential exposure pathways for human receptors are discussed in subsequent sections.

The SCEM for the site, illustrated in Figure 4-1, highlights pathways that are assumed potentially complete and significant. Chemical migration from soil to groundwater and subsequent exposure of people to chemicals in groundwater is not addressed.

Complete exposure pathways shown in the SCEM (Figure 4-1) are summarized in Table 4-1.

4.3.1 Potentially Exposed Populations

The overall scope of the analysis is graphically illustrated in the SCEM for soils at the Omega Site (Figure 4-1). The SCEM includes theoretically feasible exposures and provides a basis for discussing the likelihood and importance of potential exposure pathways at the site. As illustrated in the SCEM, potentially exposed populations are assumed to be a future on-site resident, current and future on-site and off-site indoor industrial workers, future on-site outdoor industrial workers, and a future on-site construction worker.

4.3.1.1 Hypothetical Future Residents

Hypothetical future residents that were evaluated include an adult resident, a child resident (ages 1 to 6 year old), and an adult+child resident to represent a child that remains in the area from childhood through adulthood. Potentially complete exposure pathways for residents consist of incidental ingestion of surface and subsurface soil (to 10 feet bgs) following direct contact and subsequent hand-to-mouth activities and/or dermal absorption of contaminants from soil adhered to skin surface as well as inhalation of airborne particulates from surface soil. Exposure may also occur via inhalation of VOCs in soil gas that intrudes into indoor air and in ambient air. All of these potential exposures are quantitatively evaluated for hypothetical future residents.

If the site were redeveloped for residential development, some subsurface soils may be brought to the surface during grading activities. However, typical construction in the area is slab-on-grade resulting in minimal disturbance of deeper soils. The assumption that soils as deep as 12 feet bgs might be brought to the surface during site redevelopment is likely to overestimate the degree of soil disturbance likely if new buildings are erected at the site.

4.3.1.2 Commercial/Industrial Workers

Potentially complete exposure pathways for current commercial/industrial workers consist of incidental ingestion of surface soil (to 2.2 feet bgs) following contact and subsequent hand-to-mouth activities³, incidental ingestion of dust tracked from surface into buildings, and inhalation of contaminants released from soil into air through wind or dust-generating activities (e.g., use of vehicles).

³ Under current conditions, much of the site is paved or otherwise covered by buildings or concrete. As such, this ingestion pathway is only applicable if the site is redeveloped in the future to remove buildings or pavement, thereby exposing commercial/industrial workers to bare soil.

Commercial/industrial workers could also be exposed through dermal contact with soil and interior dust and inhalation of soil gas accumulating indoors and inhalation of ambient air. Dermal exposure pathways are not expected to contribute significantly to overall exposure; however, this pathway is quantitatively evaluated. Incidental ingestion of surface soil and indoor dust and inhalation of soil gas in indoor air are also evaluated.

If the site were redeveloped in the future, some subsurface soils may be brought to the surface during grading activities. Although typical construction in the area is slab-on-grade resulting in minimal disturbance of deeper soils, future commercial/industrial workers were evaluated using deeper subsurface soils (to 12 feet bgs).

Because future development is unknown, a future outdoor industrial worker was evaluated to provide a range of potential exposures for the industrial worker. Future outdoor industrial workers were evaluated for the same exposure pathways as the indoor industrial worker with the exception of indoor air inhalation. Future outdoor industrial workers were assumed to spend all of their time outdoors.

4.3.1.3 Construction Workers

Potentially complete exposure pathways for construction workers consist of incidental ingestion of surface and subsurface soil following contact and subsequent hand-to-mouth activities, inhalation of fugitive dust through wind or dust-generating activities (e.g., use of vehicles, drilling, digging), and inhalation of contaminants released from soil gas into an excavation. Workers could also be exposed through dermal contact with soil and fugitive dust. All of these pathways are quantitatively addressed.

4.3.2 Potential Exposure Pathways

As discussed above, an exposure pathway generally consists of a chemical source, mechanism for release and transport, a point of exposure to the contaminated medium, and a route of exposure into the receptor. The absence of any one of these elements would result in an incomplete exposure pathway. Further, if one of these steps is very inefficient, exposure potential may be negligible, even though the pathway is theoretically complete. Potential exposure pathways are therefore identified in the SCEM and evaluated to determine whether they are complete and significant. The SCEM (Figure 4-1) identifies those complete pathways that may represent significant potential for exposure and are therefore the focus of the HHRA. As described above, receptors of concern include residents, commercial/industrial indoor and outdoor workers, and construction workers.

4.3.2.1 Ingestion and Dermal Contact with Groundwater

Currently, groundwater within the contaminant area (Gage unit) is not used for domestic, industrial, or agricultural purposes. Future use of groundwater for potable purposes is also unlikely due to high concentrations of TDS (Table 1-1). No evidence suggests that contamination extends to any potable aquifer that underlies the Gage

unit. If future data collection indicates that downward vertical migration has occurred, then future risk evaluations will need to address a potential drinking water pathway. Potential on-site contaminant migration to groundwater is evaluated in the On-Site Soils Remedial Investigation Report. Risks associated with potential domestic use of the contaminated groundwater plume will be evaluated in the EPA Site-wide Risk Assessment Report. Currently, this groundwater exposure pathway for ingestion is incomplete for all potential receptors.

Groundwater is 70 feet below ground surface and construction workers will not encounter groundwater in their excavations. Currently, this groundwater exposure pathway for dermal contact is also incomplete.

4.3.2.2 Incidental Ingestion and Dermal Contact with Contaminated Surface Soil and Inhalation of Particulates Released from Surface Soil

Soils at the site contain elevated levels of some chemicals as a result of past practices and activities. Currently, surface soils at the site, for the most part, are not exposed because the site is mostly covered with asphalt pavement, buildings, or other structures. Direct contact with contaminants in surface soils is likely minimal. However, for the purposes of the HHRA, the site is assumed to be uncovered (unpaved) and direct exposure to COPCs in surface soil could occur.

If areas with contaminated surface soils are left uncovered following theoretical future redevelopment, future on-site commercial/industrial workers and hypothetical future residents may contact surface soils. Potentially complete and significant pathways through which future on-site commercial/industrial workers and hypothetical future residents may contact surface soils consist of incidental ingestion, dermal contact, and inhalation of particulates released from surface soils into ambient air.

Furthermore, if the pavement and buildings at the site are removed during construction, contaminated soils may be uncovered. Future on-site construction workers may incidentally ingest and dermally contact contaminants in surface soils and may inhale particulates released from surface soils. Although these exposures are unlikely to be significant given the duration of construction activities, they will be evaluated to provide the risk manager with additional information.

4.3.2.3 Incidental Ingestion of Subsurface Soils, Dermal Contact with Subsurface Soils, and Inhalation of Particulates Released from Subsurface Soils

If the site is redeveloped in the future, future on-site construction workers, future industrial workers, and hypothetical future residents may contact contaminated subsurface soils. Construction workers may incidentally ingest and dermally contact contaminants in subsurface soils and may inhale particulates released from subsurface soils into ambient air. Hypothetical future residents and future industrial workers are assumed to be exposed to subsurface soils brought to the surface during site redevelopment and may inhale particulates released from subsurface soils.

4.3.2.4 Inhalation of Contaminants in Indoor Air

Contaminants released from contaminated soil into soil gas above the 30-foot unit may migrate below buildings and migrate indoors through foundation cracks. People working or recreating indoors in these buildings may inhale contaminants in indoor air. Because dilution of air inside buildings occurs less rapidly than that in ambient air, some accumulation of contaminants is possible where high concentrations of VOCs are present in the subsurface below buildings. In addition, heating systems can, in theory, create a negative pressure that can enhance flow of soil gas into buildings. The indoor air pathway is theoretically complete for current and future commercial/industrial workers and hypothetical future residents. Quantitative risk estimates for current commercial/industrial workers are based on measured VOC concentrations in indoor air in buildings onsite and adjacent to the site. Indoor air data collected from the former Skateland building were considered to be irrelevant since this building was demolished on April 4, 2007.

Future commercial/industrial workers were quantitatively evaluated for indoor air exposure using measured soil gas results collected from 5 to 6 feet bgs for All Parcels. Hypothetical future residents were quantitatively evaluated using this same approach except using the soil gas results from the Site Parcel and the Other Parcels. The methodology for this evaluation is further described in Section 4.4.2.4. VOCs in groundwater could also volatilize to soil gas and migrate to indoor air. Also, any VOCs originating from groundwater would be reflected in shallow soil gas samples collected at the site, and any VOCs intruding into buildings would be reflected in indoor air samples collected within these buildings.

4.3.2.5 Inhalation of Indoor Air – Volatilization during Groundwater Use

As noted above, groundwater underlying the Site and in the immediate vicinity is currently not used for any purpose nor is it likely to be used for potable use in the future due to high concentrations of TDS (Table 1-1). This groundwater exposure pathway is currently incomplete. Potential on-site contaminant migration to groundwater is evaluated in the On-Site Soils Remedial Investigation Report. Risks associated with potential domestic use of the contaminated groundwater plume will be evaluated in the EPA Site-wide Risk Assessment Report.

4.3.2.6 Inhalation of Ambient Air

Volatile COPCs in the subsurface could migrate to the surface and be released to ambient air. Construction workers and on-site industrial workers who are outdoors could inhale these chemicals. Release of vapors does not require excavation or exposure of contaminated soils to air. Vapors may migrate through the vadose zone to the surface and be released as a consequence of barometric pumping and diffusion.

Ambient air exposures for commercial/industrial workers, however, are greatly reduced by barriers to vapor migration such as buildings or pavement that currently

cover portions of the site, or could be placed on the site if redeveloped. Furthermore, because the atmosphere outside has no boundaries, any vapors that rise to surface and are released to ambient air will be quickly dispersed and concentrations would be low. Vapors migrating to indoor air are likely to present a more important exposure pathway for commercial/industrial workers and hypothetical future residents because they will spend large amounts of time indoors, and because the building and foundation represent a "trap" for migrating gases. However, commercial/industrial workers were evaluated for exposure to ambient air to provide information regarding the range of exposures. The inhalation of ambient air pathway was not evaluated for hypothetical future residents because 24-hour exposure to indoor air was assumed to provide a more conservative estimate of exposure.

Future excavation would not only remove this hardscape, but would also penetrate into the subsurface where the highest concentrations of VOCs in soil gas are observed. Release of VOCs to ambient air in an excavation is therefore also evaluated quantitatively for future construction workers.

Because measured ambient air concentrations are not likely to represent future ambient air concentrations, ambient air exposure was evaluated using measure soil gas concentrations modeled to provide ambient air concentrations. The methodology for this evaluation is further described in Section 4.4.2.4.

4.4 Exposure Parameter Assumptions

Exposure assumptions for the receptors and exposure pathways of concern are discussed below and presented in Table 4-2. A number of exposure assumptions apply to most or all exposure pathways and are discussed separately. The following sections provide pathway-specific and general exposure assumptions developed from site-specific and EPA default exposure information.

4.4.1 General Exposure Assumptions

4.4.1.1 Body Weight

In accordance with U.S. EPA guidance (1989), the value for body weight is the average weight of the receptor over the exposure period. For estimating exposures for adult residents, commercial/industrial workers and construction workers, a body weight of 70 kg is used as recommended by U.S. EPA (1989, 1991) and Cal EPA (1992, 2005c). A body weight of 15 kg is used for a child resident (CalEPA 1999).

4.4.1.2 Body Surface Area

An adult resident is assumed to wear a short-sleeved shirt, shorts and shoes, thereby exposing face, hands, forearms and lower legs. This results in a skin surface area available for contact of 5,700 cm²/event (CalEPA, 2005c). A child resident is assumed to wear a short-sleeved shirt and shorts (no shoes), thereby exposing face, hands, forearms, lower legs, and feet. This results in a skin surface area available for contact of 2,900 cm²/event (CalEPA, 2005d).

For commercial/industrial and construction workers, a total body surface area that is dermally exposed is assumed to be 3,300 cm²/event (EPA, 2001; CalEPA, 2005c). This surface area basically assumes that arms, hands and head will all be exposed at each event. Cooler weather or work that does not involve excavation, grading or other soil moving activities would likely result in lesser exposure. The dermal adherence factor or contact rate is assumed to be 0.8 mg/cm² for the construction worker (CalEPA, 2005e). The dermal adherence factor or contact rate for commercial/industrial workers is assumed to be 0.2 mg/cm² (CalEPA, 2005). These rates are estimates of soil adherence to skin and varies based on moisture content, part of the body, and type of activity.

4.4.1.3 Averaging Time

Averaging time is the period in days over which intake is averaged. For noncarcinogenic chemicals, intakes are averaged over the exposure duration (exposure duration [years] * 365 days/year). For carcinogens, intake calculations average the total cumulative dose over a lifetime (70 years * 365 days/year). Averaging times differ for carcinogens and noncarcinogens because the effects of carcinogenic chemicals are assumed to have no threshold. Therefore, any exposure to a carcinogen carries a finite risk of cancer during the individual's lifetime. Within reason, this means that a single large exposure to a carcinogen is expected to carry the same risk as the same dose divided into many small exposures. Therefore, carcinogen intakes are expressed in terms of lifetime exposures, regardless of the actual exposure duration (EPA, 1989).

4.4.1.4 Exposure Frequency

The exposure frequency is the number of days per year that an individual participates in a particular activity. For the residential scenario, the exposure frequency is 350 days per year. For the commercial/industrial indoor worker scenario, the exposure frequency is 250 days per year (EPA, 1989; CalEPA 2005c). For the commercial/industrial outdoor worker scenario, the exposure frequency is 225 days per year (EPA, 2002).

Given the relatively small size of the site (less than an acre), construction workers would not work in an excavation or with exposed soils for the entire duration of construction; therefore, the exposure frequency for CTE construction workers was assumed to be 60 days per year. This frequency is the equivalent to about 12 weeks or 3 months of construction time spent entirely within an excavation. However, to provide a range of potential exposure for the construction worker, the RME construction worker will be evaluated for an exposure frequency of 250 days.

4.4.1.5 Exposure Duration

Exposure duration is the number of years over which exposure may occur. For the residential scenario, the exposure duration is 30 years for an adult and 6 years for a child. For the adult+child scenario, the exposure duration is 24 years as an adult and 6 years as a child. For the commercial/industrial worker, an exposure duration of 25

years is used (EPA, 1997; CalEPA, 2005c). For construction workers, an exposure duration of 1 year was assumed. This duration is a typical construction period for a building or home and is reasonable for the 1-acre lot size.

4.4.1.6 Exposure Time

Exposure time is the number of hours per day spent at the site. For adult and child residents, the exposure time indoors is assumed to be 24 hours per day. For the commercial/industrial worker, an exposure time of 8 hours is used to represent the typical workday. Commercial/industrial indoor workers are assumed to spend an additional 1 hour outdoors inhaling ambient air. For the construction worker, an exposure time of 10 hours is used to represent the typical workday.

4.4.2 Pathway-Specific Exposure Assumptions

Several exposure parameters apply to specific exposure pathways and are described below.

4.4.2.1 Soil and Interior Dust Ingestion

A soil ingestion rate of 200 mg per day is used for the child resident. A soil ingestion rate of 100 mg per day is used for the adult resident and the RME commercial/industrial indoor worker scenario (CalEPA, 2005c). A CTE ingestion rate of 50 mg per day is used for the commercial/industrial indoor worker to address some potential variability in this factor (EPA 2002). Since commercial/industrial outdoor workers are likely to ingest more soil than indoor workers, a CTE ingestion rate of 100 mg per day (EPA 2002) and an RME ingestion rate of 150 mg per day is used for the commercial/industrial outdoor worker to provide a range of potential exposures.

There is no standard ingestion rate for construction workers. To address the potential variability in this factor, RME and CTE scenarios were developed. CTE and the RME soil ingestion rates of 100 and 330 mg per day, respectively, are used for the construction worker (EPA 1997; EPA 2002). The CTE ingestion rate of 100 mg per day is equivalent to the common default value used by both DTSC and EPA for an adult. The RME ingestion rate of 330 mg per day is the default ingestion rate used for a construction worker in the EPA soil screening level guidance (EPA 2002).

4.4.2.2 Inhalation of Fugitive Dust

The inhalation rate used for adult residents is 20 m³ per day, which is equivalent to 0.83 m³ per hour. The inhalation rate used for child residents is 10 m³ per day, which is equivalent to 0.42 m³ per hour (CalEPA, 2005d).

The inhalation rate used for adult commercial/industrial indoor workers under the RME scenario is 15.2 m³ per work day, which is equivalent to 1.9 m³ per hour over an 8-hour work day (EPA, 1997). This 1.9 m³/hr represents the inhalation rate of an adult male involved in moderate activities, such as major indoor repairs and alteration and climbing stairs. It seems overly conservative to assume that all commercial/industrial

workers would be engaged in such a high level of activity for the entire 8-hour work day. To address some potential variability in this factor, an inhalation rate of 1.2 m³ per hour, which is equivalent to light activity for an adult male (EPA 1997) is used for the commercial/industrial indoor workers under the CTE scenario.

Since commercial/industrial outdoor workers are likely to be more active than indoor workers, the inhalation rate for a commercial/industrial outdoor worker under the CTE scenario is 15.2 m³ per work day, which is equivalent to 1.9 m³ per hour over an 8-hour work day (EPA, 1997). This 1.9 m³/hr represents the inhalation rate of an adult male involved in moderate activities, such as major indoor repairs and alteration and climbing stairs. Under the RME scenario, an inhalation rate of 2.5 m³ per hour is used to provide a range assuming more activity.

No standard inhalation rates are available for construction workers. To address the potential variability in this factor, RME and CTE scenarios were developed. The CTE and RME inhalation rates used for adult construction workers are 2.5 and 4.8 m³ per hour, respectively (EPA, 1997). This 2.5 m³ per hour estimate is based on the inhalation rate of an adult male involved in moderate activities, such as major indoor repairs and alterations and climbing stairs. The 4.8 m³ per hour estimate is based on the inhalation rate of an adult male involved in heavy activities, such as vigorous physical exercise and climbing stairs while carrying a load. Activities listed are only examples of the level of effort for different inhalation rates. Outdoor construction workers would be engaged in other tasks, but the level of effort implied is still appropriate. Since it is unlikely that a construction worker will be engaged in these levels of activities for their entire 10-hour workday for every workday of the year, use of these inhalation estimates is assumed to be conservative.

4.4.2.3 Inhalation of Indoor Air

Inhalation of indoor air was evaluated for current commercial/industrial workers using measured indoor air concentrations to directly estimate risk related to indoor air exposure. For future commercial/industrial workers and for hypothetical on-site future residents, risk estimates were based on measured concentrations of VOCs in soil gas modeled to represent indoor air concentrations. The USEPA advanced soil gas spreadsheet implementation of (Windows™ - Excel) the Johnson and Ettinger vapor intrusion model (SG_ADV_Feb04.xls last modified February, 2004) was used to estimate potential indoor air concentrations from soil gas concentrations by calculating flux of chemicals through a foundation, taking into account building size and ventilation. Site-specific criteria entered into the model are as follows (and summarized in Table 4-3):

- Soil gas data from only the shallow depths sampled (5 to 6 feet bgs) were used because soil gas from the shallow portion of the vadose zone would be the most likely to migrate into onsite buildings. For the model soil gas sample depth was assumed to be 5 feet bgs.

- An average soil temperature of 67°F (19.4°C) was assumed per Figure A-1 in DTSC Indoor Air Guidance (Feb. 2005)
- Site soil was assumed to be loam soil, to be conservative and health-protective.
- For a commercial/industrial worker, the model was adjusted to account for an exposure frequency and duration of 250 days per year and 25 years, respectively, to represent a typical commercial worker. Standard default values of exposure time of 24 hours per day, exposure frequency of 350 days per year, and exposure duration of 30 years were used for the residential scenario.
- For a commercial/industrial worker, the model was adjusted to account for an exposure time of 18.24 hrs to adjust the model for the commercial/industrial worker inhalation rate of 15.2 m³/d compared to the 20 m³/day that the model assumes for residents.
- Toxicity criteria were updated using the online Office of Environmental Health Hazard Assessment (OEHHA) Toxicity Criteria Database⁴ and the online USEPA Integrated Risk Information System (IRIS)⁵ database.
- For a commercial worker, the exchange rate was changed to a value of 1.0 air exchanges per hour. This value is consistent with the minimal ventilation requirements per the 2001 Energy Efficiency Standards for Nonresidential Buildings.⁶ This ventilation rate is appropriate for a new commercial/industrial facility building. Standard default value for the exchange rate (0.5 air exchanges per hour) was used for the residential scenario.
- The enclosed space height for the commercial worker was assumed to be 276 cm to represent a 9-foot ceiling, while 244 cm was used for residents to represent an 8-foot ceiling.

Other model input parameters include the physical/chemical properties of COPCs. Chemical properties (such as air and water diffusivities and Henry's law constants) were either found in the model, researched for inclusion in the model or calculated using the references provided in the user's guide for the Johnson and Ettinger Model (USEPA, 2004). Model defaults were used when site specific values were not available. Johnson and Ettinger calculations are provided in Appendix A-4.

The building concentration (C_{building}) reported on the INTERCALCs sheet of the J&E model was used as the indoor air concentration that the receptor is exposed to indoors and was used in the RAGS D Tables.

4.4.2.4 Inhalation of Ambient Air

Ambient Air - Chronic Exposure Scenario

Karami, et al. (1987) along with the USEPA Draft Soil Screening Guidance (1994) were used to estimate ambient air concentrations for chronic exposure scenarios (residents and commercial workers). According to Karami, et al. (1987), assuming that the concentration at the surface is very small, vapor flux through soil can be estimated using the equation (see Table 4-4 for definitions of the variables in the following equations):

$$J = -D_s \times (-C_s)/L \quad (\text{Eqn. 1-1})$$

Where

$$D_s = D_i (P_a^{10/3}/P_t^2) \quad (\text{Eqn. 1-2})$$

$$P_a = P_t - P_w \quad (\text{Eqn. 1-3})$$

The emission rate of the site can then be calculated by:

$$E = J \times A_{\text{site}} \quad (\text{Eqn. 1-4})$$

Assuming a simple box model, the ambient air concentration can then be calculated using the following equation:

$$C_{\text{air}} = E / (L_s \times V \times D_H) \quad (\text{Eqn. 1-5})$$

Proposed parameters (default and site-specific) for use in the equations are provided in Table 4-4. Calculations for ambient air from soil gas for the chronic scenarios are provided in Appendix A-5, Tables A5-1 through A5-6. The results are provided in the exposure concentration tables presented in Section 4.5.

Ambient Air - Short-term Exposure Scenario

For estimating ambient air concentrations for short-term exposure scenario (construction worker), the same methodology used to calculate ambient air for the chronic exposure described above was used. For the construction worker, it was assumed that contamination extended from the surface to the 30-foot unit, therefore, the 95 UCL for soil gas concentrations ranging from 5 to 30 feet deep for samples were used. The low of the range (5 feet) was used as the depth of the soil layer in the flux calculation to be conservative.

Proposed parameters (default and site-specific) for use in the equations for the short term scenario are provided in Table 4-5. Calculations for ambient air from soil gas for the subchronic scenarios are provided in Appendix A-5, Tables A5-7 through A5-12. The resulting ambient air concentrations are provided in the exposure concentration tables presented in Section 4.5.

4.4.2.5 Exposure to Lead

Risks for lead were evaluated using EPA's Adult Lead Methodology for occupational exposures and the DTSC Leadsread model for residential exposures.

EPA Adult Lead Model

Risks for lead were evaluated using EPA's Adult Lead Methodology for occupational exposures and comparing to the threshold level of no more than 5 percent probability of blood lead levels exceeding 10 µg/dL. The EPA Adult Lead Methodology was used for occupational exposures instead of the DTSC Leadsread model because EPA Adult Lead Methodology includes a calculation for blood lead levels for an adult worker fetus.

Some key assumptions made in the EPA Adult Lead Methodology include:

- Exposure duration for commercial/industrial worker and the RME construction worker was revised to reflect 250 days per year.
- Exposure concentration for lead in soil was assumed to be 65.4 mg/kg (95% UCL for lead as shown in Table 4-6 for surface soil) for current commercial/industrial workers and 59.9 mg/kg (as shown in Table 4-7 for surface and subsurface soil to 12 feet bgs) for future commercial/industrial workers; and for the RME construction worker.

Default values were used for the remaining model parameters.

Lead calculations are presented in Appendix A-2A. Risks from lead exposure are not calculated for the CTE construction worker. A relatively constant lead intake over a minimum of 90 days, possibly more, is necessary to achieve a new quasi-steady state blood lead concentration and the exposure duration of the construction worker was estimated to be only 60 days. The Adult Lead Methodology is not capable of resolving such temporal effects. However, risks from lead exposure are calculated for the RME construction worker.

DTSC Leadsread Model

VOC transport from the subsurface to indoor air was modeled using the USEPA Lead concentrations in air and soil were evaluated using the most current available version of the Leadsread lead risk assessment spreadsheet (v. 7.0) provided by the DTSC (2000). The following assumptions were made for this model:

- Lead concentration in drinking water at the site was assumed to be equivalent to the California maximum contaminant level (MCL) (15 ug/L).
- Lead concentration in air was assumed to be 0.028 ug/m³, the default average air concentration.

- Maximum lead concentration detected in the soil samples from this investigation was assumed to be the exposure concentration calculated for the lead in surface and subsurface soil from 0 to 12 feet bgs (59.9 mg/kg).
- Leadsread default values were used for the remaining model parameters.

Leadsread results for the hypothetical future residents are presented in Appendix A-2B.

4.5 Exposure Point Concentrations

Exposure point concentrations are estimated chemical concentrations a receptor will contact over an exposure period. Because of the uncertainty associated with any estimate of exposure, 95 percent upper confidence levels (UCLs) of the arithmetic mean are generally used as exposure point concentrations. Exposure point concentrations are calculated appropriately as 95 percent UCL of the arithmetic mean only when associated with an exposure unit within which exposures can reasonably be assumed to occur randomly. Exposure point concentrations are estimated using this approach for all COPCs for each exposure media identified for the site. EPA's statistical program *ProUCL* (EPA, 2001), were used to test data distributions and to compute UCLs of population means. For these calculations, non-detects were assumed to be equivalent to half of the detection limit. For datasets with less than 5 samples, the number of samples was too few to calculate a UCL and the maximum detected concentration was used as the exposure point concentration. Exposure point concentrations for all datasets assessed quantitatively are summarized in Tables 4-6 through 4-25.

Exposure point concentrations for measured indoor air concentrations were not determined using UCL calculations due to the small number of samples and nature of indoor air concentrations. Instead, minimum and maximum detections within each building were used as the indoor air exposure point concentrations. This approach assumes that some partitioning of air might occur within buildings and therefore that each data point might represent an exposure point concentration for workers in different locations within a building. Use of minimum and maximum concentrations might then be interpreted to provide a range of possible exposures and risks that might occur concurrently. Indoor air EPCs are provided on Tables 4-8 to 4-15.

Soil gas concentrations were used in the Johnson and Ettinger model to estimate indoor air exposure concentrations. The indoor air model results are provided in Tables 4-17 to 4-20. Johnson and Ettinger calculations are provided in Appendix A-4. Ambient air calculations are provided in Appendix A-6. These results are presented in Tables 4-21 to 4-25.

4.6 Chemical Intake

The amount of chemical that is taken into a person's body following exposure is referred to as chemical intake. Intake is expressed in units of milligrams of chemical

per kilogram of body weight per day (mg/kg-day), and is referred to as chronic daily intake (CDI). CDI depends on the concentration of chemicals in media at the point of human contact (exposure point concentration), and exposure assumptions specific to the receptor population, including frequency and duration of exposure, body weight, and contact rate. EPA guidance indicates that exposure assumptions should be chosen so that their combination results in an estimate of the reasonable maximum exposure (RME) for the exposure pathway. RME is the highest exposure that is within the range of possible exposures at the site (EPA, 1989). RME is designed to be conservative yet designed to prevent unrealistic, or "worst case" estimates from serving as the basis of risk management decisions. A range of exposure estimates is provided by estimating the central tendency exposure (CTE) for each exposure pathway. CTE uses exposure assumptions that predict an average exposure to an individual. Presentation of both the RME and CTE risks for the site provides the risk manager with a range of potential risks.

CDI are calculated using exposure point concentrations for the media of concern and the exposure assumptions described in Section 3. CDIs are estimated for each selected exposure pathway. The equations used to calculate CDIs for each exposure pathway are shown below.

4.6.1 Ingestion of Soils and Interior Dust

To determine CDIs associated with incidental ingestion of chemicals in solid media (e.g., surface soils and interior dust), the following equation is used (EPA, 1989).

$$CDI (mg/kgday) = \frac{CS \times IR \times CF \times FI \times EF \times ED \times BAF}{BW \times AT}$$

Where:

- CDI = Chronic Daily Intake ((mg/kg)/day)
- CS = Chemical Concentration in Soil or Dust (mg/kg)
- IR = Ingestion Rate (mg/day)
- CF = Conversion Factor (10⁻⁶ kg/mg)
- FI = Fraction Ingested from Contaminated Source (unitless)
- EF = Exposure Frequency (days/year)
- ED = Exposure Duration (years)
- BAF = Bioavailability Factor for COPC in Soil or Dust (unitless)
- BW = Body Weight (kg)

AT = Averaging Time (days)

4.6.2 Dermal Contact with Soils and Interior Dust

To determine CDIs associated with dermal contact with chemicals in solid media (e.g., surface soils and interior dust), the following equation is used (EPA, 1989).

$$CDI (mg/kgday) = \frac{CS \times SA \times AF \times ABS \times CF \times EF \times ED}{BW \times AT}$$

Where:

- CDI = Chronic Daily Intake ((mg/kg)/day)
- CS = Chemical Concentration in Soil or Dust (mg/kg)
- SA = Skin surface area exposed (cm²)
- AF = Soil to skin adherence factor (mg/cm²)
- ABS = Absorption fraction of chemical from soil
- CF = Conversion Factor (10⁻⁶ kg/mg)
- EF = Exposure Frequency (days/year)
- ED = Exposure Duration (years)
- BW = Body Weight (kg)
- AT = Averaging Time (days)

4.6.3 Inhalation of Fugitive Dust, Indoor Air, or Ambient Air

To determine CDIs associated with inhalation of COPCs in fugitive dust, indoor air or ambient air, the following equation is used (EPA, 1989).

$$CDI (mg/kgday) = \frac{CA \times IhR \times ET \times EF \times ED}{BW \times AT}$$

Where:

- CDI = Chronic Daily Intake ((mg/kg)/day)
- CA = Chemical Concentration in Air (mg/m³)
- ET = Exposure Time (hours/day)
- IhR = Inhalation Rate (m³/hour)

EF = Exposure Frequency (days/year)

ED = Exposure Duration (years)

BW = Body Weight (kg)

AT = Averaging Time (days)

**Table 4-3
Johnson and Ettinger Model Input Parameters for Site-Specific Screening**

Variable	Description	Default Value	Proposed Site-Specific Value	Source
C_{sg}	Soil gas concentrations	Site-specific	Chemical-specific	95 UCL for soil gas concentrations ranging from 5 to 6 feet deep for samples collected on the Omega site parcel
θ_t	Soil total porosity	Site-specific	0.399	Model default for Loam soil
θ_w	Soil water-filled porosity	Site-specific	0.148	Model default for Loam soil
θ_a	Soil air-filled porosity	Site-specific	0.251	Model default for Loam soil
ρ_s	Soil dry bulk density	Site-specific	1.59	Model default for Loam soil
k	Soil intrinsic permeability	Site-specific	2.29E-09	Model default for Loam soil
$^{\circ}T$	Soil and groundwater temperature	Site-specific	67°F (19.4°C)	Figure A-1 from DTSC 2005
ΔP	Indoor – outdoor pressure differential	40 g/cm-s ²	Default	USEPA 2004
η	Crack-to-total area ratio	0.005	0.0004	Calculated based on recommended 0.1 cm crack width (USEPA 2003). ⁽¹⁾
E_b	Indoor air exchange rate - residential	0.5 / hour	Default	USEPA 1997
	Indoor air exchange rate - commercial	1.0 / hour	Default	CEC 2001
L_{crack}	Foundation slab thickness	Site-specific	15 cm	
L_b, W_b	Building dimensions – length x width	1000 cm x 1000 cm	Default	DTSC 2005
H_b	Building dimension – height - residential	244 cm (8 ft)	Default	DTSC 2005
	Building dimension – height - commercial	none	276 cm (9 ft)	
L_f	Foundation depth below grade – building with no basement	15 cm	Default	USEPA 2004
L_s	Soil gas sampling depth below grade	Site-specific	152.4 cm (5 ft)	Site data
ED, EF, ET	Exposure Duration, Exposure Frequency, Exposure Time – residential	30 years, 350 days/yr, 24 hrs/day	Default	USEPA 1997
ED, EF, ET	Exposure Duration, Exposure Frequency, Exposure Time - commercial	none	25 years, 250 days/yr, 18.24 hrs/day ⁽²⁾	USEPA 1997

USEPA = United States Environmental Protection Agency cm = centimeters
 DTSC = Department of Toxic Substances Control ft = feet
 CEC = California Energy Commission g/cm-s² = grams per centimeter – seconds squared

- (1) For future buildings, a soil gas advection rate of 5 liters per minute should be used, as proportionally increased for future building size, rather than the defaults for indoor – outdoor pressure differential, crack-to-total area ratio, and foundation thickness.
- (2) Exposure time of 18.24 hrs to adjust the model for the commercial/industrial worker inhalation rate of 15.2 m³/d compared to the 20 m³/day that the model assumes for residents.

MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY - Surface and Subsurface Soil 0 to 12 ft bgs
Omega Chemical Site - Whittier, California

Scenario Timeframe:	Future
Medium:	Surface & Subsurface Soil to 12'
Exposure Medium:	Surface & Subsurface Soil to 12'

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean ⁽¹⁾	95% UCL of Distribution ⁽¹⁾	Maximum Detected Concentration	Exposure Point Concentrations			
						Value	Units	Statistic ⁽²⁾	Rationale
	NICKEL	mg/kg	22.28	24.51	55	24.51	mg/kg	UCL-NP	UCL is greater than Max
	PCB-1254 (AROCOR 1254)	mg/kg	0.06	0.34	0.5	0.34	mg/kg	UCL-NP	
	PHENANTHRENE	mg/kg	0.40	2.96	5	2.96	mg/kg	UCL-NP	
	POLYCHLORINATED BI PHENYLS, TOTAL	mg/kg	0.50	No UCL	0.5	0.5	mg/kg	Max	
	PYRENE	mg/kg	0.30	1.88	3.1	1.88	mg/kg	UCL-NP	
	SILVER	mg/kg	0.54	0.61	1.2	0.61	mg/kg	UCL-NP	
	TETRACHLOROETHENE	mg/kg	85.68	922.68	4.3	4.3	mg/kg	Max	
	THALLIUM	mg/kg	2.56	3.41	2	2	mg/kg	Max	
	TRICHLOROETHENE	mg/kg	7.56	51.89	0.028	0.028	mg/kg	Max	
	VANADIUM	mg/kg	43.89	46.95	71	46.95	mg/kg	95% UCL-N	
	ZINC	mg/kg	80.23	94.57	350	94.57	mg/kg	UCL-NP	

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

(2) The Shapiro-Wilk test was used to test the normality/ lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data.

NA: too few detections to calculate a UCL

mg/kg: milligram per kilogram.

Statistics: Maximum Detected Value (Max), 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP), 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

(2) Due to the small dataset, 95% UCL was not calculated. Minimum and maximum detections were used to represent the range of exposure concentrations.

ug/m³: microgram per cubic meter.

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

The Shapiro-Wilk test was used to test the normality/ lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data.

(2) Soil gas values modeled to provide indoor air concentrations using EPA Advance Soil Gas Model using Johnson and Ettinger algorithms for Commercial Worker Exposure. See Appendix A-4.

ug/m³: microgram per cubic meter.

ND: Not determined. Indoor air concentration could not be calculated because physical parameters for constituent were not available.

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

The Shapiro-Wilk test was used to test the normality/lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data.

(2) Soil gas values modeled to provide indoor air concentrations using Karami, et al (1987) equations along with the USEPA Draft Soil Screening Guidance (1994) to estimate Outdoor air concentrations from soil gas. See Appendix Tables A6-5 and A6-6.
ug/m³: microgram per cubic meter.

ND: Not determined. Indoor air concentration could not be calculated because physical parameters for constituent were not available.

Section 5

Section 5

Toxicity Assessment

The purpose of a toxicity assessment is to review and summarize available information on the potential for each chemical of potential concern (COPC) to cause adverse effects in exposed individuals. Adverse effects include both noncarcinogenic and carcinogenic health effects in humans. For most adverse effects caused by chemicals, a positive relationship exists between dose (intake of a chemical through a particular exposure pathway, such as ingestion) and response. Generally, as dose increases, type and severity of adverse response also increases. Further, time of onset of toxic responses often shortens.

A key facet of any toxicity assessment is the use of dose-response information to describe a quantitative relationship between human exposure and potential for adverse health effects. Quantitative toxicity criteria are generally numerical expressions developed by EPA of the relationship between chronic average daily dose (exposure) and toxic response (adverse health effects). As described below, separate toxicity criteria are developed for assessment of carcinogenic and noncarcinogenic health effects.

Sources of toxicity information included, in order of descending priority, are:

- Office of Environmental Health Hazard Assessment (CalEPA) Toxicity Criteria Database or USEPA's Integrated Risk Information System (IRIS) - The more health-protective toxicity value of CalEPA and IRIS will be used, with the exception of TCE (see Section 7).
- USEPA criteria documents
- Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profiles

This section explains how toxicity criteria for carcinogens and noncarcinogens are developed and expressed, and summarizes toxicity values for each COPC. The general basis for the development of toxicity values for carcinogens and noncarcinogens is presented in subsections 5.1 and 5.2, respectively, along with a summary of the toxicity values for all COPCs.

5.1 Carcinogens

5.1.1 Evidence of Carcinogenicity

USEPA has developed a classification system for carcinogens, which characterizes the overall weight of evidence of carcinogenicity based on the availability of human, animal, and other supportive data. Three major factors are considered:

- The quality of evidence from human studies
- The quality of evidence from animal studies

- Other supportive data assessed to determine whether the overall weight of evidence should be modified

USEPA classification system for the characterization of the overall weight of carcinogenicity has the following five categories:

1. Human Carcinogen. This category indicates that there is sufficient evidence from epidemiological studies to support a causal association between an agent and cancer.
2. Probable Human Carcinogen. This category generally indicates that there is at least limited evidence from epidemiological studies of carcinogenicity to humans (Group B1) or that, in the absence of adequate data on humans, there is sufficient evidence of carcinogenicity in animals (Group B2).
3. Possible Human Carcinogen. This category indicates that there is limited evidence of carcinogenicity in animals in the absence of adequate data on humans.
4. Not Classified. This category indicates that the evidence for carcinogenicity in animals is inadequate.
5. Evidence of Noncarcinogenicity to Humans. This category indicates that there is evidence for noncarcinogenicity in at least two adequate animal tests in different species or in both epidemiological and animal studies.

5.1.2 Cancer Slope Factors

Carcinogenic toxicity criteria are usually provided as cancer slope factors (CSFs) in units of excess risk per milligram of chemical per kilogram of body weight per day ((mg/kg-day)⁻¹). These factors are based on the assumption that no threshold exists for carcinogenic effects and any dose is associated with some finite carcinogenic risk. Chemical-specific toxicity criteria for the carcinogens at the site are presented in Table 5-1.

USEPA has used a variety of specialized models to estimate the upper bound risk of carcinogenesis for a number of compounds. Data from animal or epidemiological studies are used to determine slope factors, which are expressed as (mg/kg-day)⁻¹ for a lifetime exposure. The CSF describes the increase in an individual's risk of developing cancer over a 70-year lifetime per unit of exposure where the unit of exposure is expressed as mg/kg-day.

CSFs are calculated using methods protective of human health and are based on the assumption that cancer risks decrease linearly with decreasing dose. The 95 percent upper confidence limit estimate for the slope is used in most cases to compensate for animal to human extrapolation and other uncertainties. The resulting CSFs are considered to be upper range estimates that are unlikely to underestimate carcinogenic potential in humans.

When the upper-bound CSF is multiplied by the lifetime average daily dose of a potential carcinogen, the product is the upper-bound lifetime individual cancer risk associated with exposure at that dose. The calculated risk is thus an estimate of the increased likelihood of cancer resulting from exposure to a chemical. For example, if the product of the CSF and the average daily dose is 1×10^{-6} , the predicted upper-bound cancer risk for the exposed population is one in one million, or 0.0001 percent. This risk is in addition to any "background" risk of cancer not related to the chemical exposure.

Calculation of risk often relies on data derived from chronic animal bioassays. The likelihood that an animal carcinogen is also a human carcinogen is a function of the following factors:

- The number of tissues affected by the chemical
- The number of animal species, strains, sexes, and number of experiments and doses showing a carcinogenic response
- The occurrence of clear-cut dose-response relationships as well as a high level of statistical significance of the increased tumor incidence in treated compared to control groups
- A dose-related decrease in time-to-tumor occurrence or time-to-death with tumor
- A dose-related increase in the proportion of malignant tumors

Animal studies are usually conducted using relatively high doses to observe adverse effects. Because humans are expected to be exposed at lower doses, data are adjusted using a mathematical model. Data from animal studies are fitted to a linearized multi-stage model and a dose-response curve is obtained. The low-dose slope of the dose-response curve is subjected to various adjustments (e.g., calculation of 95 percent UCL), and inter-species scaling factors are often applied to derive slope factors for humans. Dose-response data derived from human epidemiological studies are fitted to dose-time-response curves on an individual basis. These models provide conservative but plausible estimates of upper limits on lifetime risk. Although the actual risk is unlikely to be higher than the estimated risk, it could be considerably lower. In some instances, it may even be zero.

5.2 Noncarcinogens

Toxicity criteria for noncarcinogens, or for significant noncarcinogenic effects caused by carcinogens, are provided as reference doses (RfD) for oral and inhalation exposure and are expressed in units of milligram of chemical per kilogram of body weight per day (mg/kg-day). RfDs may be interpreted as thresholds below which adverse effects are not expected to occur in the most sensitive populations even if the exposure occurs continuously over a lifetime. Chemical-specific toxicity criteria for the noncarcinogens at the site are presented in Table 5-2.

RfDs are usually derived from no observable adverse effect levels (NOAELs) taken either from human studies, often involving workplace exposures, or from animal studies, and are adjusted downward using uncertainty or modifying factors. For example, a modifying factor of 2 to 10 may be applied if the database on a particular chemical lacks information on possible reproductive or developmental toxicity.

Uncertainty factors are generally applied to adjust for the possibility that humans are more sensitive than experimental animals and that there may be sensitive subpopulations of humans (e.g., children, pregnant women, individuals with hay fever or asthma). Depending upon the information available, other factors may also be applied.

RfDs are presented in units of mg/kg-day for comparison with estimated chronic daily intake into the body. Chronic exposure in this instance is not clearly defined, but need not be a lifetime exposure. Generally, exposures must continue for several years to be considered chronic. Intakes less than the RfD are not likely to cause adverse health effects. Chronic daily intakes greater than the RfD indicate a possibility for adverse effects. Whether such exposures actually produce adverse effects, however, is a function of a number of factors such as accuracy of uncertainty factors applied to the NOAEL, appropriateness of animal models used in studies extrapolated to humans, and potential for the chemical to cause effects in organs or systems (e.g., reproductive and immune systems) that have not been adequately studied. Generally, protective assumptions made by USEPA in deriving RfDs will, in most cases, mean that exposures slightly in excess of the RfD will be associated with a low risk for adverse effects, with the probability of adverse effects increasing with increasing exposure.

RfDs can be generated for subchronic exposures as well as chronic exposures. Subchronic is generally assumed to be exposures of several weeks to a few years. Since construction workers at the site are expected to be exposed for no more than 60 days (see Table 4-2), a subchronic reference dose is most appropriate for assessing risks to these receptors. Subchronic RfDs are derived in the same manner as RfDs for chronic exposure, except that data from shorter term animal studies, or human exposures, are used.

EPA has not published conventional quantitative toxicity criteria for lead because available data suggest a very low or possibly no threshold for adverse effects, even at exposure levels that might be considered background. Any significant increase above such background exposures could represent a cause for some concern. In lieu of evaluating risk using typical intake calculations and toxicity criteria, DTSC has developed a spreadsheet model for prediction of blood-lead levels in receptors exposed to lead from a variety of sources, including soil, dust, air, and water. Estimated blood-lead levels are compared to target blood-lead concentrations to assess possible risks. This model is further discussed in Section 6.

Inhalation toxicity values for the constituents at the site are provided in Tables 5-3 and 5-4.

5.3 Adjustment of Toxicity Values

Oral toxicity values reported in IRIS and CalEPA are based on an administered dose. Therefore, these values need to be adjusted to reflect inefficiencies that would exist through gastrointestinal absorption (EPA 2004). If oral absorption is complete, then the absorbed dose is equivalent to the administered dose and the oral value does not need to be adjusted. However, if the chemical has poor gastrointestinal absorption, then the absorbed dose is actually much smaller than the administered dose and the toxicity factor needs to be adjusted. For chemicals without a gastrointestinal absorption adjustment factor, 100 percent absorption is assumed. As the gastrointestinal absorption adjustment factor decreases, the contribution of the dermal pathway to the overall risk increases. These adjusted toxicity values are used in the calculation of risks and hazards for the dermal pathway. Gastrointestinal absorption adjustment factors for the COPCs are listed in Table 5-5.

Oral toxicity factors also need to be adjusted to represent a dermally absorbed dose to be used in the evaluation of the dermal exposure pathway. RAGS Part E guidance only provides dermal adjustment factors for semi-volatile organics. Volatile organics would tend to volatilize from the skin and exposure to this group of chemicals would better be assessed through the inhalation pathway. Although inorganics would remain in the soil and available for dermal contact, their toxicity is highly dependent on speciation and too little toxicity data is available on this group of chemicals to provide reliable dermal absorption factors. Dermal adjustment factors for the COPCs are listed in Table 5-5. RAGS Part E guidance recommends that dermal exposure to chemicals that do not have dermal absorption fractions to be addressed qualitatively in the uncertainty section, Section 7.

ZINC	NA	mg/kg/day ⁻¹	NA	NA	mg/kg/day ⁻¹	D	IRIS	07/24/2007

Footnotes:

(1) Dermal absorption adjustment is a combination of the dermal absorption fraction (ABSd) and the gastrointestinal absorption (ABSGI) as presented in Table A3-4.2. = ABSGI/ABSd so the absorbed cancer slope factor = SFo *ABSd/ABSGI

(2) OEHHA considers naphthalene to be a carcinogen by inhalation only, therefore, the oral cancer slope factor is not used in this risk assessment.

EPA-NCEA: USEPA Region III Provisional Peer Reviewed Toxicity Values for Superfund (PPRTV) (EPA 2005b).

IRIS: Integrated Risk Information System (EPA 2005a).

na: Chemical is listed, no value is available.

ne: Chemical has not been evaluated by EPA for evidence of human carcinogenicity.

ni: No information available.

mg/kg/day⁻¹: milligram per kilogram-day.

ZINC	chronic	3.0E-01	mg/kg/day	NA	NA	mg/kg/day	Dec. erythrocyte Cu	3	IRIS	07/24/2007

Footnotes:

(1) Dermal absorption adjustment is a combination of the dermal absorption fraction (ABSd) and the gastrointestinal absorption (ABSGI) as presented in Table A3-4.2. = ABSGI/ABSd

so the absorbed reference dose = RfDo * ABSGI/ABSd

EPA-NCEA: USEPA Region III Provisional Peer Reviewed Toxicity Values for Superfund (PPRTV) (EPA 2005b).

HEAST: Health Effects Assessments Summary Tables (EPA 1997b)

IRIS: Integrated Risk Information System (EPA 2005a).

na: Chemical is listed, no value is available.

ni: No information available.

nl: Chemical is not listed.

CNS: Central Nervous System.

mg/kg/day: milligram per kilogram per day

(1) EPA 2004. Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Ju Exhibit 3-4. "—" signifies that no dermal absorption fraction from soil was provided. VOCs are assumed to volatilize and are accounted for in the inhalation pathway and are highly dependent on the speciation of the compound and there is too little data to determine a reasonable default value.

(2) ABS_d values for 1,4-dioxane, bromoform, benzyl alcohol, dieldrin, DDE, DDD, isophorone, and xylenes were obtained from EPA 2004 Region 9 PRG Table.

(3) EPA 2004. Risk Assessment Guidance for Superfund Volume I Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Ju Exhibit 4-1. Default value of 1 signifies that compound was not recommended for adjustment for gastrointestinal absorption efficiencies.

Section 6

Section 6

Risk Characterization

In the final step of risk assessment, exposure estimates are combined with toxicity criteria presented in the toxicity assessment to estimate carcinogenic risks and noncarcinogenic hazards. EPA Risk Assessment Guidance for Superfund (RAGS) calculations are used to evaluate the risks. Lead (Pb) is an exception. Potential health hazards associated with exposure to lead are estimated using the Adult Lead Methodology as discussed in Section 3.

Equations used for risk and hazards calculations are presented below.

6.1 Risk Equations

Potential cancer risks and potential non-cancer hazards are separately calculated using standard methods from EPA as described in the following sections.

6.1.1 Cancer Risks

Cancer risks are estimated by multiplying exposure estimates for carcinogenic chemicals by corresponding cancer slope factors. The result is a risk estimate expressed as the incremental odds of developing cancer. Commonly, risks (or odds) of developing cancer of one to 100 in one million (1×10^{-6} to 1×10^{-4}) or less are considered to fall within a potentially acceptable range, although decisions on the need for remediation or mitigation are made on a site-by-site basis. Lower risks are typically considered de minimis, while higher risks are often deemed unacceptable (EPA, 1992). In such instances, mitigation of risks may be considered necessary.

Carcinogenic risks are estimated as the incremental probability that an individual will develop cancer over a lifetime as a direct result of exposure to potential carcinogens (EPA, 1989). The estimated risk is expressed as a unitless probability. The equation for calculating the potential excess cancer risk for each carcinogenic chemical is:

$$\text{Risk}_i = \text{CDI}_i \times \text{CSF}_i$$

Where:

Risk_i = Lifetime Excess Cancer Risk from exposure to chemical_i

CDI_i = Chronic Daily Intake for chemical_i in milligrams per kilograms per day (mg/kg-day)

CSF_i = Inhalation Cancer Slope Factor (mg/kg-day)⁻¹

An estimate of an individual's incremental excess cancer risk from potential exposure to multiple chemicals emitted from the site is then calculated by summing the chemical-specific excess cancer risks (i.e., Total risk = $\sum \text{Risk}_i$).

6.1.2 Chronic Non-Cancer Hazards

For COPCs that are not classified as carcinogens and for those carcinogens known to cause adverse health effects in addition to cancer, chronic non-cancer hazard indices are calculated by dividing exposure estimates by reference doses. As discussed in Section 4, *Non-Cancer Reference Doses*, reference doses are estimates of highest exposure levels that would not cause adverse health effects even if exposures continue over a lifetime. The potential for exposure to result in non-carcinogenic effects is evaluated by comparing estimated daily dose to the chemical-specific non-cancer RfD. The ratio of exposure to reference dose is termed the hazard quotient (HQ). A HQ greater than one indicates an exposure greater than that considered safe. Risks or odds of adverse effects cannot be estimated using reference doses. However, because reference doses are developed in a conservative fashion, HQs only slightly higher than one are generally accepted as being associated with low risks (or even no risk) of adverse effects, and that potential for adverse effects increases as the HQ gets larger.

Impacts of exposure to multiple chemicals are accounted for by adding estimated HQs for non-carcinogenic chemicals that affect the same target organ or tissue in the body. Addition of HQs for COPCs that produce effects in similar organs and tissues results in a HI that reflects possible cumulative hazards. To evaluate the potential for non-carcinogenic adverse health effects from simultaneous exposure to multiple chemicals, hazard quotients for all chemicals that affect the same target organs are summed yielding hazard indices (HI). In general practice, all hazard quotients are summed to yield a total hazard index. If that total hazard index is greater than one, then the hazard quotients for the different chemicals are separated by toxicity endpoint and then summed to determine the total hazard index for each toxicity endpoint. The RAGS D tables provided in Appendix A-3 have been modified to show the total hazard index followed by a breakdown of the hazard index by toxicity endpoint.

Equations for calculating the chemical-specific hazard quotients and the overall hazard index are:

$$HQ_i = \frac{CDI_i}{RfD_i}$$

$$HI = \sum HQ_i$$

Where:

HI = Hazard Index

HQ_i = Hazard Quotient for individual chemical_i

CDI_i = Chronic daily intake for chemical_i (mg/kg-day)

RfD_i = Chronic Non-cancer Inhalation Reference Dose for chemical_i (mg/kg-day)

6.2 Risk Characterization Results

Cancer risks and non-cancer hazards for current and future receptors at the Site are summarized in Tables 6-1 and 6-2, respectively. The risk calculation spreadsheets are provided in Appendix A.

Tables 6-1 and 6-2 show both minimum and maximum risks and hazards to show the possible range of risks. Minimum risks and hazards were calculated using the minimum detected exposure point concentration and maximum risks and hazards were calculated using either the maximum detected or 95 UCL exposure point concentration. This approach was used to address the possibility for compartmentalized vapor concentrations inside buildings. If air circulation limited mixing among different area/rooms, any of the individual indoor air detections could be viewed as a separate exposure point concentration. That is, all risks associated with indoor air VOC concentrations could be extant at the same time. Instead of calculating risks for all of the data, minimum and maximums are calculated to show the possible range of risks possible given the potential for compartmentalization.

6.2.1 Cancer Risks

Total cancer risk estimates for current commercial/industrial worker on the Site parcel (Three Kings Construction CTE, 2E-5 to 9E-5 and RME, 4E-5 to 1E-4; Star City Auto Body CTE, 3E-5 to 6E-5 and RME, 4E-5 to 9E-5) are above the point of departure of one in one million but within the EPA risk range (Table 6-1). Cancer risks for the industrial/commercial worker are primarily attributable to inhalation of indoor air (Figure 6-1).

Total cancer risk estimates for future commercial/industrial indoor worker based on data from All Parcels (CTE, 9E-6 to 3E-4 and RME, 1E-5 to 5E-4) are above the EPA risk range (Table 6-2). Total cancer risk estimates for future commercial/industrial outdoor worker based on data from All Parcels (CTE, 1E-5 to 2E-5 and RME, 1E-5 to 2E-5) are above the point of departure of one in one million but within the EPA risk range. Total cancer risk estimates for the future construction worker (CTE, 2E-7 to 4E-7 and RME, 1E-06 to 2E-6) on the Site parcel; on the Others Parcels (CTE, 2E-7 to 4E-7 and RME, 1E-06 to 2E-6); and on All Parcels (CTE, 2E-7 to 3E-7 and RME, 1E-06 to 2E-6) are above the point of departure of one in one million but within the EPA risk range. Total cancer risk estimates for future residents (adult, 5E-5 to 3E-3; adult+child, 8E-5 to 3E-3; and child, 4E-5 to 1E-3) on the Site parcel and on the Others Parcels (adult, 2E-5 to 4E-3; adult+child, 4E-5 to 5E-3; and child, 3E-5 to 2E-3) are above the EPA risk range. Cancer risks for the future industrial/commercial indoor worker and residents are primarily attributable to inhalation of indoor air (Figure 6-2). Cancer risks for construction workers and future industrial/commercial outdoor workers are primarily attributable to exposure to soil (Figure 6-3). The following discussions separately describe risks associated with soil and indoor air exposure in more detail.

Risks Associated With Soil Exposure

Risks associated with surface soil exposure only account for about 10 percent of the total cancer risks for the current commercial/industrial worker in the Three Kings

Construction building and 15 percent in the Star City Auto Body building and are within the middle of the EPA risk range (CTE, 9E-6 and RME, 1E-5) (Table 6-1, Figure 6-1). Similarly risks associated with soil exposure for the future commercial/industrial worker account for about 2 percent of the total cancer risks for the indoor worker (CTE, 8E-6 and RME, 1E-5) and 56 percent for the outdoor worker (CTE, 1E-5 and RME, 1E-5), and are also within the middle of the EPA risk range (Figure 6-2). Risks associated with surface soil exposure for current and future commercial/industrial indoor workers are not likely to be realized. In a commercial/industrial setting, most of the surface soil at the site will be covered by buildings, concrete/asphalt driveways, and landscaped grounds. Little bare soil would be available for contact and estimated risks for this pathway are greatly exaggerated.

Risks associated with surface soil exposure only account for about 1 percent of the total cancer risks for the adult and adult+child residents and 2 percent for the child resident and are within the middle of the EPA risk range (adult, 2E-5; adult+child, 4E-5; and child, 3E-5) (Table 6-2, Figure 6-2).

For construction workers, the risks associated with oral and dermal exposure to surface and subsurface soil and inhalation of fugitive dust account for 53 to 69 percent of the total cancer risks and are within the lower EPA risk range (CTE, 2E-7 and RME, 1E-6) (Table 6-2, Figure 6-3). Because there is only one set of soil data for the site, soil risks are the same for the Site Parcel, Others Parcels, and All Parcels. However, site-related contamination is likely to be highest near source areas at the site, and similar or lower levels of COPCs are anticipated in adjacent properties that were not sampled. Thus, minimal risks from exposure to site-related chemicals in soils are expected in surrounding parcels. Benzo(a)pyrene accounts for about 44 to 48 percent of the cancer risk from soil exposure for construction workers (RME and CTE, respectively). PCB-1254 and total PCBs collectively accounts for about 25 to 28 percent of the cancer risk from soil exposure for construction workers (RME and CTE, respectively).

Risks Associated With Indoor Air Exposure

Potential inhalation of indoor air is the primary contributor to cancer risks (Three Kings Construction CTE, 1E-5 to 8E-5 and RME, 2E-5 to 1E-4; Star City Auto Body CTE, 2E-5 to 5E-5 and RME, 3E-5 to 7E-5) for a current industrial/commercial worker on the Omega Site parcel (Table 6-1, Figure 6-1). Inhalation of benzene accounts for 38 (Star City) to 46 (Three Kings) percent of the cancer risk. Inhalation of methylene chloride accounts for 38 percent of the cancer risk for commercial/industrial workers at Three Kings, while inhalation of PCE accounts for 50 percent of the risk at Star City Auto Body (Figure 6-4). Onsite, sources at Star Auto Body and/or 3 Kings Construction could be responsible for some or all of the benzene detected in indoor air.

For the other buildings, cancer risks were assessed only for the inhalation of vapors intruding into indoor air. Estimated Inhalation cancer risks for these parcels were similar to, or lower than, those for the Site parcel, except for the West Parcel -

Terrapave (Figure 6-5). All inhalation cancer risks were above the point of departure of one in one million but within the EPA risk range.

Inhalation cancer risks for the five parcels are summarized as follows (Figure 6-4). Cancer risks for the north parcel (Medlin & Sons CTE, 1E-5 to 3E-5 and RME, 2E-5 to 5E-5) are primarily attributable to exposure to PCE (48 percent) with lesser contributions from carbon tetrachloride (21 percent), benzene (12 percent), and TCE (10 percent). Cancer risks for the west parcel (TerraPave CTE, 4E-5 to 1E-4 and RME, 6E-5 to 1E-4) are primarily attributable to exposure to PCE (88 percent) with lesser contributions from carbon tetrachloride (4 percent) and benzene (5 percent). Cancer risks for the south parcel - Bishop (CTE, 1E-5 to 3E-5 and RME, 2E-5 to 5E-5) are primarily attributable to exposure to PCE (71 percent) with lesser contributions from carbon tetrachloride (10 percent) and benzene (14 percent). Cancer risks for the south parcel - LA Carts (CTE, 9E-6 to 1E-5 and RME, 1E-5 to 2E-5) are primarily attributable to exposure to benzene (56 percent) with lesser contributions from carbon tetrachloride (20 percent) and PCE (8 percent). Cancer risks for the south parcel - Oncology Care (CTE, 1E-5 and RME, 2E-5) are primarily attributable to exposure to benzene (39 percent) with lesser contributions from carbon tetrachloride (26 percent) and chloroform (17 percent).

Benzene and carbon tetrachloride are observed in similar concentrations in ambient air and indoor air for parcels other than the Omega site itself. Ambient levels of benzene were reported between 0.8 to 1.09 $\mu\text{g}/\text{m}^3$, compared to indoor air concentrations for adjacent parcels (0.89 to 2.17 $\mu\text{g}/\text{m}^3$, with only one concentration above 2 $\mu\text{g}/\text{m}^3$). Benzene concentrations in shallow soil gas samples (5 to 6 feet bgs) are greater on-site (45 to 2,074 $\mu\text{g}/\text{m}^3$ - Table 3-7b) than on the adjacent parcels (8 to 16 $\mu\text{g}/\text{m}^3$ - Table 3-7c). This same trend is visible in the deeper soil gas (5 to 30 feet bgs) with benzene concentrations ranging from 31 to 3,828 $\mu\text{g}/\text{m}^3$ on-site (Table 3-8b) compared to the range of 3 to 89 $\mu\text{g}/\text{m}^3$ (Table 3-8c) on the adjacent parcels. Ambient concentrations of carbon tetrachloride ranged from 0.5 to 0.63 $\mu\text{g}/\text{m}^3$, compared to indoor air concentrations ranging from 0.5 to 1.3 $\mu\text{g}/\text{m}^3$. Further, carbon tetrachloride is reported infrequently in the subsurface (once among 46 shallow soil gas samples); carbon tetrachloride in the subsurface does not appear to represent a significant source. Carbon tetrachloride was also not detected in shallow soil gas samples (5 to 6 feet bgs - Table 3-7c) or the deeper soil gas samples (5 to 30 feet bgs - Table 3-8c) collected from the Other Parcels. Although benzene in soil gas could be partially responsible for indoor air concentrations, indoor air concentrations of carbon tetrachloride may well have its source in ambient air rather than soil vapors. This interpretation is supported by the lack of PCE and other chemicals in indoor air in the LA Carts/Oncology Care buildings. These VOCs are found in very high concentrations in soil gas. If subsurface vapors were intruding into buildings, one would expect to find PCE along with benzene and carbon tetrachloride in indoor air.

The high concentrations of individual VOCs in groundwater, most notably PCE, suggest the presence of a dense non-aqueous phase liquid (DNAPL). MIP data, discussed in the following section, demonstrate the highest content of VOCs within the capillary fringe, suggesting that DNAPL is present as residual saturation in this

depth interval. The DNAPL is likely a continuous source of groundwater contamination at the former Omega Chemical property, as evidenced by persistently high VOC concentrations in groundwater at Putnam Street.

Chloroform, though detected in soil gas and groundwater, is also common in municipal water as a result of chlorination, and is a common indoor air contaminant. Chloroform concentrations detected in indoor air are relatively low (0.14 to 0.68 $\mu\text{g}/\text{m}^3$) compared to shallow soil gas samples (5 to 6 feet bgs) concentrations of 93 to 14,640 $\mu\text{g}/\text{m}^3$ for on-Site (Table 3-7b) and 73 to 1,757 $\mu\text{g}/\text{m}^3$ for adjacent parcels (Table 3-7c). Although the indoor air concentrations are greater than Cal-modified Region 9 ambient air PRG for chloroform (0.35 $\mu\text{g}/\text{m}^3$), they are still considerably below the Agency for Toxic Substances and Diseases Registry (ATSDR) established acute inhalation minimal risk level (MRL) of 500 $\mu\text{g}/\text{m}^3$ (0.1 ppm) and chronic inhalation MRL of 100 $\mu\text{g}/\text{m}^3$ (0.02 ppm) for chloroform. ATSDR's public health statement for chloroform also states that amount of chloroform normally expected to be in the air ranges from 0.1 to 0.25 $\mu\text{g}/\text{m}^3$ (0.02 to 0.05 ppb) of air and from 2 to 44 ppb in treated drinking water (ATSDR 1997). The indoor air concentrations are certainly consistent with a source in municipal water. Again, this interpretation is supported by the lack of PCE and other chemicals in indoor air in the LA Carts/Oncology Care buildings. These VOCs are found in very high concentrations along with chloroform in soil gas. Although chloroform in soil gas could be partially responsible for indoor air concentrations, one would expect to find these other VOCs along with chloroform in indoor air if subsurface vapors were intruding into buildings. Chloroform was not reported in ambient air samples. Without the contributions of benzene, carbon tetrachloride, and chloroform which could be attributable to background, inhalation cancer risks for the industrial workers at the buildings would be as follows:

- North Parcel - Medlin & Sons: RME, 3E-5 (compared to RME, 5E-5 with benzene, carbon tetrachloride, and chloroform)
- West Parcel - TerraPave: RME, 1E-4 (compared to RME, 1E-4 with benzene, carbon tetrachloride, and chloroform)
- South Parcel - Bishop: RME, 3E-5 (compared to RME, 5E-5 with benzene, carbon tetrachloride, and chloroform)
- South Parcel - LA Carts: RME, 4E-6 (compared to RME, 2E-5 with benzene, carbon tetrachloride, and chloroform)
- South Parcel - Oncology Care: RME, 3E-6 (compared to RME, 2E-5 with benzene, carbon tetrachloride, and chloroform)

The above considerations suggest that background risks, unrelated to vapor intrusion of site-related contaminants is in the range of 1×10^{-5} . Such risk suggests that incremental risks possibly related to site contamination are a significant portion of total risks associated with VOCs in indoor air. Background risks account for essentially all risks at the LA Carts/Oncology Care buildings and 10 to 50 percent of total risks for surrounding parcels.

Risks associated inhalation of indoor air for the future adult resident (Site Parcel: 3E-5 to 3E-3, Others Parcel: 3E-6 to 4E-3), adult+child resident (Site Parcel: 4E-5 to 3E-3, Others Parcel: 4E-6 to 5E-3), and the child resident (Site Parcel: 2E-5 to 1E-3, Others Parcel: 1E-6 to 2E-3) range above the EPA risk range (Table 6-2, Figure 6-6). Inhalation of PCE in soil gas accounts for 90 to 95 percent of the total inhalation risk (Figure 6-7).

Risks associated inhalation of indoor air for the future commercial/industrial indoor worker (CTE, 8E-7 to 3E-4 and RME, 1E-6 to 5E-4) calculated from soil gas for All Parcels also result in risks above the EPA range (Table 6-2, Figure 6-8). PCE in soil gas accounts for 90 percent of the total inhalation risk (Figure 6-7).

Risks Associated With Ambient Air Exposure

Risks associated inhalation of ambient air for the future commercial/industrial outdoor worker (CTE, 2E-8 to 8E-6 and RME, 3E-8 to 1E-5) calculated from soil gas for All Parcels result in risks below or at the lower end of the EPA range. For construction workers, the risks associated with inhalation of ambient air are also all within the EPA risk range (Site: CTE, 1E-9 to 1E-7 and RME, 8E-9 to 1E-6; Other Parcels: CTE, 7E-11 to 1E-7 and RME, 5E-10 to 1E-6); and All Parcels: CTE, 5E-10 to 1E-7 and RME, 4E-9 to 8E-7) (Table 6-2, Figure 6-8). PCE in soil gas accounts for 84 to 85 percent of the total inhalation risk (Figure 6-9).

6.2.2 Chronic Non-Cancer Hazards

Chronic non-cancer hazards for the current commercial/industrial worker (Three Kings CTE, 0.4 to 1.2 and RME, 0.6 to 2; Star City Auto CTE, 0.5 to 5.1 and RME, 0.8 to 8) are above the threshold of 1. HIs for the commercial/industrial worker are primarily attributable to inhalation of indoor air (Figure 6-11). Total HIs for future residents (Site Parcel: adult, 0.7 to 30; adult+child 1.4 to 39; and child, 4.1 to 74; Other Parcels: adult, 0.4 to 45; adult+child 1 to 58; and child, 3.4 to 108) are above the target threshold. Total HIs for future commercial/industrial workers (Indoor: CTE, 0.15 to 4 and RME, 0.3 to 7; and Outdoor: CTE, 0.2 to 0.3 and RME, 0.3 to 0.5) based on data from All Parcels are above the target threshold for indoor workers and below the target threshold for outdoor workers. Total hazard indices for the construction worker (Site Parcel: CTE, 0.08 to 0.13 and RME, 0.8 to 1.2; Other Parcels: CTE, 0.08 to 0.12 and RME, 0.8 to 1.2; and All Parcels: CTE, 0.08 to 0.12 and RME, 0.08 to 1.1) are below or at the target HI of one. HIs for the construction worker are primarily attributable to exposure to soil (Figure 6-12). The following discussions separately describe the hazards associated with soil exposure and indoor air in more detail.

Hazards Associated With Soil Exposure

Hazards associated with surface soil exposure only account for 3 (Star City Auto Body) to 14 (Three Kings Construction) percent of the total HIs for the current and future commercial/industrial worker and are below the target threshold of one (Table 6-2, Figure 6-10). For future commercial/industrial worker, HIs associated with oral and dermal exposure to surface and subsurface soil and inhalation of fugitive dust are below the target threshold of one for the CTE scenario (indoor: 0.14; outdoor: 0.2) and RME scenario (indoor: 0.3; outdoor: 0.3). Risks associated with surface soil exposure for the current and future commercial/industrial indoor workers are not likely to be

realized. In a commercial/industrial setting, most of the surface soil at the site will be covered by buildings, concrete/asphalt driveways, and landscaped grounds. Little bare soil would be available for contact and estimated risks for this pathway are greatly exaggerated.

For future residents, HIs associated with oral and dermal exposure to surface and subsurface soil are below the target threshold of one for the adult scenario (0.3) and the adult+child scenario (0.9) and above the threshold for the child scenario (3.2).

For future construction workers, HIs associated with oral and dermal exposure to surface and subsurface soil and inhalation of fugitive dust are below the target threshold of one for the CTE scenario (0.08) and RME scenario (0.8).

Hazards Associated With Indoor Air Exposure

The highest HQs for the Site parcel for the current commercial/industrial worker are at the Star City Auto Body (total hazard index of 8) and are attributable to inhalation exposure to toluene and acetone, which account for 54 and 13 percent of site-related inhalation HIs, respectively (Figure 6-13). When the total HI is divided by target organ, HI associated with kidneys is the largest portion (66 percent of the total HI, or an HI of 3.3, CTE and 5.3, RME). HI associated with body weight effects is the second largest (23 percent of the total HI, or an HI of 1.2, CTE and 1.8, RME). HIs for all other organs are less than the threshold of 1.

HIs for the current commercial/industrial worker on the Site parcel at the Three Kings building (total hazard index of 2) are attributable to inhalation exposure to toluene (18 percent), m,p-xylenes (27 percent), methylene chloride (21 percent), PCE (12 percent), and benzene (12 percent). When the total HI is divided by target organ, HIs for all organs are less than the threshold of 1.

For the other five parcels, HIs were assessed only for the inhalation of vapors intruding into indoor air. Inhalation HIs for the other buildings were all below the HIs for Star City Auto Body and slightly above the target HI of one (ranging from 0.1 to 1.8), indicating that non-cancer hazards at these parcels are minimal. Inhalation HIs for the five parcels are summarized as follows (Figures 6-13 and 6-14). HIs for the north parcel (Medlin and Sons, CTE, 0.09 to 0.65 and RME, 0.1 to 1; Medlin and Sons North, CTE, 0.05 and RME, 0.08) are primarily attributable to exposure to acetone (55 percent) with a lesser contribution from PCE (32 percent). HIs for the west parcel (TerraPave, CTE, 0.5 to 1.28 and RME, 0.7 to 1.8) are primarily attributable to exposure to PCE (90 percent). HIs for the south parcel - Bishop (CTE, 0.1 to 0.4 and RME, 0.2 to 0.6) are primarily attributable to exposure to PCE (76 percent) with a lesser contribution from 1,1-DCE (6 percent). HIs for the south parcel - LA Carts (CTE, 0.06 to 0.8 and RME, 0.1 to 1.3) are primarily attributable to exposure to toluene (74 percent) with a lesser contribution from acetone (15 percent). HIs for the south parcel - Oncology Care (CTE, 0.09 and RME, 0.14 to 0.15) are primarily attributable to exposure to toluene (20 percent), 1,2-DCA (23 percent), benzene (14 percent) and acetone (11 percent). The highest HIs by toxicity endpoints for these other parcels are

at Terrapave, where the total HI to the liver is 1.7, and at LA Carts, where the total HI to the kidney is 1.3. All other HIs by toxicity endpoints were below one.

The highest HQs for residents are calculated from data from the Other Parcels (adult: 45, adult+child: 58, and child 108) and are attributable to inhalation exposure to PCE and 1,1-DCE, which account for 90 and 6 percent of HIs for the child resident on the Other Parcels and 86 and 8 percent of HIs for the child resident on the Site Parcel (Figure 6-16). When the total HI for the child resident on Other Parcels is divided by target organ, HI associated with liver is the largest portion (93 percent of the total HI, or an HI of 101 for the child). HIs for the unspecified endpoints is 7 and the HIs for all other calculated endpoints (body weight effects and kidneys) are less than the threshold of 1.

Inhalation HIs for the future commercial/industrial indoor worker calculated from data on All Parcels range above the threshold of 1 (CTE, 0.009 to 4.2 and RME, 0.014 to 7) (Figure 6-17). As shown in Table 6-2, inhalation of indoor air is attributable for most of this hazard. Similar to the resident, PCE and 1,1-DCE account for most of the hazard, contributing 84 and 9 percent, respectively (Figure 6-16). When the total HI is divided by target organ for the RME worker, HI associated with liver is the largest portion (90 percent of the total HI, or an HI of 6.4). HIs for all other endpoints are less than the threshold of 1.

Hazards Associated With Ambient Air Exposure

Total ambient air HIs for future commercial/industrial outdoor worker (CTE, 0.0002 to 0.11 and RME, 0.0003 to 0.15) based on data from All Parcels are below the target threshold (Figure 6-17). When the total HI is divided by target organ for the RME worker, HI associated with liver is the largest portion (70 percent of the total HI, or an HI of 0.3). HIs for all endpoints are less than the threshold of 1.

For construction workers, the hazards associated with inhalation of ambient air are below the target threshold of one (Site Parcel: CTE, 0.0002 to 0.05 and RME, 0.002 to 0.4; Other Parcels: CTE, 0.00006 to 0.04 and RME, 0.0005 to 0.3; and All Parcels: CTE, 0.00012 to 0.04 and RME, 0.0009 to 0.3). As shown in Figure 6-12, roughly 30 percent of the hazards for the future construction worker are related to inhalation of ambient air. Figure 6-18 shows the RME construction worker ambient air hazards by chemical. Hazards are higher on the Site Parcel than on the Other Parcels and All Parcels. When the total HI is divided by target organ for the RME Site Parcel construction worker, HI associated with unspecified endpoints is the largest portion (69 percent of the total HI, or an HI of 0.8). HIs for all calculated endpoints (liver, body weight effects, and kidneys) are less than the threshold of 1.

6.2.3 Risks Associated with Lead Exposure

Ingestion of soil by receptors would likely be incidental from hand to mouth activities. The EPA Adult Lead Methodology was used to assess exposure to lead for the current and future industrial worker. The lead model was adjusted for the exposure frequency discussed in Section 4.

For the current commercial/industrial worker, the 95% UCL for lead detected in surface soil was 65.4 mg/kg. The model results indicate that the geometric mean blood lead concentration might range from 1.7 to 1.9 µg/dl for an adult worker. The 95th percentile blood lead concentration of a fetus in an adult worker would range from 5.2 to 6.8 µg/dl. This range is considerably below a typical target of 10 µg/dL. More importantly, the probability that fetal blood levels for pregnant adult worker would exceed the target of 10 µg/dL is 0.6% to 1.7%. Where the probability of exceeding 10 µg/dL is 5 percent or less, lead exposures are typically deemed to fall into an acceptable range.

For the future commercial/industrial worker and RME construction workers, the 95% UCL for lead detected in soil to 12 feet bgs was 59.9 mg/kg. The model results indicate that the geometric mean blood lead concentration might range from 1.7 to 1.9 µg/dl for an adult worker. The 95th percentile blood lead concentration of a fetus in an adult worker would range from 5.2 to 6.7 µg/dl. This range is considerably below a typical target of 10 µg/dL. More importantly, the probability that fetal blood levels for pregnant adult worker would exceed the target of 10 µg/dL is 0.6% to 1.7%. Where the probability of exceeding 10 µg/dL is 5 percent or less, lead exposures are typically deemed to fall into an acceptable range.

The DTSC Leadsread model was used to assess exposure to lead for hypothetical future residents. The lead model was adjusted for the exposure frequency discussed in Section 4. The 95% UCL for lead detected in soil to 12 feet bgs was 59.9 mg/kg. The Leadsread results predict that chronic exposure to 59.9 mg/kg of lead in the soil will result in blood-lead concentrations of 6.7 micrograms per deciliter (ug/dL) in normal nonpica children in the 99th percentile and 8.0 ug/dL in pica children in the 99th percentile. Blood-lead concentrations in adult residents are predicted to be 3.9 ug/dL. All of these values are well below the CalEPA acceptable level of 10 ug/dL. Although the EPA adult lead model was used for the industrial worker, it should be noted that the Leadsread occupational calculation for an adult results in a blood lead concentration of 3.9 ug/dL, which is also well below the CalEPA acceptable level of 10 ug/dL.

Therefore, risks due to lead exposure do not appear to be sufficiently high to warrant action.

6.3 Evaluation of Empirical Attenuation Factors

Site data are available for both shallow soil gas collected near building foundations, and indoor air for these same buildings. The ratios of indoor air concentrations to soil gas concentrations provide a measure of possible attenuation factors. Such factors are only valid for chemicals for which ambient air and/or background concentrations do not make a substantial contribution to indoor air contamination. For the analysis of attenuation factors, PCE, TCE and Freon 113 were selected as reasonable indicator factors. These three chemicals are present in very high concentrations in shallow soil gas and were observed in indoor air in ratios similar to those in soil gas. Indoor air concentrations for these VOCs seem likely to reflect, at least in large measure, vapor intrusion.

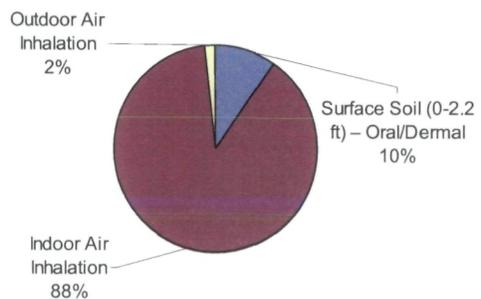

To estimate possible ranges for attenuation factors, minimum indoor air concentrations, by parcel, were divided by maximum soil gas concentrations to give lower end point. The opposite calculation provides the upper range estimate. The mid range was estimated by the ratio of average indoor air concentrations by parcel to average soil gas concentrations. Results of the calculation are provided in Table 6-3.

The range of possible attenuation factors are consistent from parcel to parcel, with average ratios falling in the range of $7E-06$ to $3E-04$. The upper end of this range is consistent with attenuation factors for commercial/industrial workers estimated using the Johnson and Ettinger model. The latter estimates are in the range of $1E-04$ and $4E-04$.

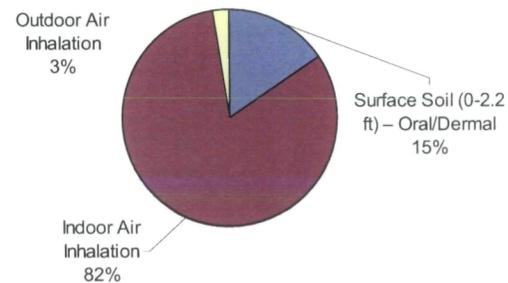

The overall range of estimates for attenuation factors is quite wide, from $7E-07$ to $2E-02$. Data are insufficient to determine if the extremes of this range are within those possible for current site conditions. However, soil gas concentrations vary considerably along building perimeters, suggesting that some integrating of concentrations for both soil gas and indoor air might be appropriate for estimating attenuation factors. However, whether an appropriate integration is simple averaging cannot be determined.

Average attenuation factors estimated from empirical results provide some confidence in the results of modeling, in that at least some of these estimates fall within the modeled range. Overall, however, empirical estimates appear too variable to use in estimating site-specific PRGs. A range of site-specific PRGs that spans almost 5 orders of magnitude would be difficult to use in defining remedial strategies. Site-specific PRG calculations are provided in Appendix D.

Section 7

Section 7

Uncertainties

7.1 Uncertainties in the Risk Assessment Process

A degree of uncertainty is associated with all phases of a risk assessment. This section describes the potential impact of uncertainties associated with the database, exposure assumptions, and toxicity assessment on the final step of the risk assessment and risk characterization. In addition, uncertainties inherent in risk characterization are identified and discussed.

7.2 Uncertainties in the Database

Site data appear to provide an adequate characterization of current conditions at the site. Numerous samples were collected across the site for all media, and in many cases sampling locations were biased towards contaminated (or formerly contaminated) areas. That is, much of the site characterization effort focused on and near known source/release areas. Moreover, more than one round of sampling was completed for each media, reducing any concerns with taking a "snap shot" of site conditions that was not representative of typical conditions. This concern is particularly relevant to soil gas and indoor air concentrations which could theoretically vary considerably over time.

Overall, available data for the site can be considered representative, or somewhat biased toward areas of contamination. COPC selection based on these data is likely to include chemicals that present little risk rather than exclude chemicals that may be of concern. Risk assessment based on available data can be used with confidence to produce a conservative (protective) evaluation of potential human health risks.

7.3 Uncertainties with Exposure Assessment

Methods used in this risk assessment are conservative; methods are used that are more likely to overestimate than underestimate possible health risks. For example, risks and hazards are calculated for individuals that are likely to be exposed at locations where COPC concentrations are predicted to be highest. Further, individuals are assumed to be exposed for almost all days of the year and for many years to maximize estimates of possible exposure. Resulting cancer risk estimates represent upper-range predictions of exposure, and therefore health risk, which may be associated with living or working on the site. By protecting hypothetical individuals that receive the highest exposures (i.e., people living at or working at locations for which the highest emissions are predicted), the risk assessment will also be protective for actual members of the population that are not as highly exposed.

Potential risks and hazards associated with vapor intrusion under current conditions were considered on a parcel-by-parcel basis, using data from indoor air sampling for existing buildings. These estimates allow better visualization of potential site-impacts at the Omega Site and at surrounding properties, as well as providing an indication of possible current Site-related health risk, if any. This approach eliminates the

possibility that combining data within a larger exposure area (e.g. the Omega Site and all surrounding parcels) dilute out parcels with high and low potential for vapor intrusion.

7.3.1 Exposure Populations

Oncology Care Medical Associates is located in the South parcel, at the northeast corner of Putnam Street and Washington Boulevard. It is a 3,720 square foot, U-shaped, one level building, with an exterior paved parking lot. The building has a reception/waiting area in the front, with offices, examination rooms, a medicine storage/mixing room, and treatment room occupying the remainder of the building. This facility serves as an outpatient medical facility where patients receive oncology treatment. The chemical inventory of Oncology Care only noted several medications and an obvious odor of isopropyl alcohol, which is used for surface disinfecting throughout the facility. The HVAC evaluation revealed three AC units on the roof. The units appeared to be fairly new, and did have intakes allowing outside air to be drawn into the building. The medicine storage/mixing room contained two fume hoods for mixing medicines. The larger fume hood apparently discharges fumes from the top of the unit to the indoor air

Oncology patients are likely to have suppressed immune systems due to chemotherapy or radiology. As such, they are a potentially sensitive population that may be more affected by exposure to chemicals than the average healthy person. However, most oncology patients would not be attending the facility for the decades assumed in a risk assessment for a staff worker. Oncology treatment periods are usually less than a year at a time with patients going to the facility for a few hours a week depending on the course of treatment. Although some patients require more than one course of treatment or may have to return to the facility if the cancer reoccurs, their total time spent at the facility is still considerably less than a staff worker. Current workers at Oncology Care were assessed based on measured indoor air concentrations. As noted in Section 6, indoor air risks for workers at Oncology Care are $2E-05$, which is within the middle of the EPA risk range.

7.3.2 Exposure Concentrations

The site is relatively small and will likely remain as single parcel; therefore, it was appropriately assessed as a single exposure unit. The same argument holds true for surrounding properties that are also relatively small and likely to remain as single parcels. Thus, separate evaluation of vapor intrusion for these parcels is also justified. Exposure point concentrations for individual is, however, subject to some uncertainty because dividing Site data by parcel reduces the size of the datasets used for EPC calculations.

Generally, 95% UCL concentrations were used as the exposure concentrations for site media. A 95% UCL is a statistic meaning that there is a 95% confidence (probability) that the concentration on the site will be at this level. For samples with non-detectable levels of a contaminant, one-half of the reporting limit is substituted when calculating the 95% UCL.

For example, PCE is the primary COPC of concern at the site. The 95% UCL for PCE in soil gas from 5 to 6 feet bgs for the Site parcel is $1,355,479 \mu\text{g}/\text{m}^3$ (199,923 ppbv) while PCE concentrations detected in the 22 indoor air samples ranged from 16,272 to $3,390,000 \mu\text{g}/\text{m}^3$. Only 6 of the 22 PCE detections had concentrations higher than $1,355,479 \mu\text{g}/\text{m}^3$ (199,923 ppbv). It is unlikely that a receptor would spend all of his time (in the case of a commercial/industrial worker - 8 hours a day, 250 days a year for 25 years) standing at the location of the highest PCE detection. In such a manner, use of the 95% UCL as the exposure concentration provides a reasonable estimate of exposure.

In some cases, however, small datasets forced the use of the maximum detected concentration in indoor air as the EPC. Use of the maximum is likely overestimate possible indoor air concentrations. In these cases, additional conservatism may be included in risk and hazard estimates.

For a conservative estimate of potential health risks from soil gas for the future industrial worker and hypothetical residential scenarios, samples collected from 5 to 6 feet bgs collected from 2004 to 2006 were used to calculate the exposure concentrations for soil gas. Soil gas concentrations can vary seasonally and the availability of multiple rounds of soil gas sampling increased confidence in exposure point concentrations. Higher concentrations of some COPCs were found at greater depths bgs, but available data provide no indication that the observed vertical profile of soil gas concentrations is not representative of typical conditions at the site. That is, the profile did not change notably between sampling events. Thus, higher concentrations found below 6 feet bgs do not suggest that current modeling for vapor intrusion significantly underestimates potential risks or hazards. Soil gas samples collected between 5 and 30 feet bgs were used in the evaluation of the construction worker since construction workers may be present in excavations.

Measured indoor air data was used to represent indoor air under current scenarios. Due to the small number of samples collected in the buildings, 95% UCLs could not be calculated and maximum detected concentrations were used instead. The use of maximum concentrations to represent all exposures likely results in an overestimate of risks. Therefore, minimum detected concentrations in the buildings were also evaluated to provide the risk manager with a range of risks that could be experienced by potential receptors.

7.3.3 Exposure Pathways

Risks and hazards calculated for future commercial/industrial worker soil exposure pathways assume that soil is available for contact. However, the site is currently covered by buildings and other impervious surfaces, and it is unlikely that soils would remain uncovered (i.e., bare) following redevelopment, eliminating much potential for exposure to Site soils. Therefore, risks and hazards associated with the exposure pathways of dermal contact, soil ingestion, and inhalation of particulates are ceiling estimates, and actual risks are likely to be negligible.

7.3.4 Estimates of Indoor and Ambient Air Concentrations

Indoor air concentrations for the site for current scenarios were estimated directly from measured indoor air concentrations. Indoor air concentrations are likely to vary during the course of a day and seasonally, and may be influenced by sources of VOCs inside of buildings and, conceivably, in ambient air. Variations in concentrations over the course of a day were addressed in the sampling by continuous sample collection over an 8-hour period, during typical work hours. These samples provide an overall daily average concentration, which is most appropriate for assessing chronic daily exposure. In addition, samples were taken in various work areas within each building to help ensure that vagaries of building ventilation did not produce spurious results. Thus, available data are reasonable estimates of daily exposure on sample collection days.

Seasonal variation was addressed by collecting samples on two or more occasions. Results from these separate sampling events were very similar for a given building. It is likely that available data reasonably describe likely indoor air quality for each of the buildings sampled. Risks estimated on the basis of measured indoor air concentrations probably fall into upper range of those possible for the site and surrounding parcels.

A final issue concerning indoor air measurements is that they cannot be used directly to estimate future indoor air concentrations should the site and/or surrounding parcels be redeveloped. While it is not possible to predict future indoor air concentrations, it is reasonable to assume that new buildings would be constructed following existing commercial building codes which are likely to require a vapor barrier and substantial ventilation. Moreover, new buildings would have intact buildings with few if any cracks that would facilitate vapor intrusion. Thus, vapor intrusion can be predicted to be less for new construction than is suggested by current indoor air data. Also, current indoor air data are likely to include non-site-related VOCs from building and/or ambient air. Current data therefore are likely to overestimate site-related risks and hazards.

However, over time, cracks may develop in the new foundation and holes may develop in the vapor barriers. In addition, building codes may require engineered fill to be placed under the foundation, which could be more permeable than the clay assumed to currently be in place and the loam assumed in the modeling. In addition, redevelopment of the area could include the construction of multi-story buildings with elevators. Elevators in multi-story buildings require subsurface foundations, and elevator movement can create a piston effect that could potentially draw vapors into the building as zones of negative pressure are created during elevator rise. These types of considerations for multi-story buildings are not taken into account in the Johnson and Ettinger Model. Therefore, it is uncertain whether current data overestimate or underestimate site-related future risks and hazards.

Risk estimates developed in this document for future vapor intrusion used measured soil gas concentrations modeled using a spreadsheet model to estimate future indoor air concentrations. Modeling is associated with some uncertainty, and inputs to the

model were chosen to ensure that theoretical risks and hazards would be over- rather than underestimated. For example, to be conservative and health protective, loam was selected as the soil type for the Johnson and Ettinger model. However, the measured effective conductivity (K_s) for shallow soils at the site is significantly lower than the default value (0.5 cm/hr) used for loam in the model. Measured effective conductivities for the site are shown in Table 7-1.

Outdoor air concentrations for the future industrial worker were also estimated using measured soil gas concentrations. As noted above, modeling introduces additional uncertainties into the estimates. A comparison of modeled outdoor air to actual measured outdoor air is provided in Table 7-2. As shown in the table, measured and modeled PCE and TCE concentrations are similar. However, measured and modeled concentrations for some chemicals like acetone and benzene are very dissimilar. This variance is consistent with other outdoor sources (such as benzene in car exhaust) contribute to ambient air concentrations at the site. Further, outdoor air samples collected at the site were not intended to provide an estimate of local air quality. For example, one outdoor air sample was collected immediately outside of the front door at Skateland. Concentrations of VOCs in this sample undoubtedly reflect VOCs leaking from within the building. At the time of sampling, concentrations of VOCs inside Skateland were a few to several hundred $\mu\text{g}/\text{m}^3$.

Finally, estimates of releases of VOCs to ambient air are likely to overestimate any possible releases. For the windfield (box model) assumed for future industrial workers, an air concentration of PCE of about $7.7 \mu\text{g}/\text{m}^3$ is associated with a risk of $1\text{E}-06$. PCE is used for this analysis since it is the major contributor to site-related risks via inhalation. This concentration implies a flow of soil gas across the soil-air interface of about $0.000132 \text{ m}^3/\text{sec}$. Over the course of a year, all of the soil gas within 6 feet of ground surface over 0.7 acres (about 3/4 of the site) would have been released to ambient air. As discussed in Section 3.3.7, shallow soil gas concentrations are typically greater than concentrations measured deeper in the soil profile. Also, concentrations of VOCs beneath neighboring properties are substantially lower than those below the site. Thus, as soil gas in the most highly contaminated areas was released, it would likely be replaced by deeper or adjacent soil gas with lower PCE concentrations, or would be replaced with "clean" ambient air. Thus, even if volumetric flow rates did not change, PCE emission rates and therefore ambient air concentrations would be less than those predicted as soon as soil gas began to be replaced from less contaminated sources.

After the course of 25 years, the volume of shallow soil gas beneath the Site would be replaced about 17 times, implying that none of the higher concentrations of PCE in soil gas would remain, and that release rates across the soil-air interface would have decreased dramatically.

It seems unlikely that the amounts of PCE and other VOCs in shallow soil gas are sufficient to support long-term ambient air concentrations that would be of concern for future workers at or near the site. Intrusion into indoor air remains a more viable exposure pathway because of the relatively low indoor air exchange rates used in

evaluating intrusion. Lower exchange rates imply that lower emissions (intrusion rates) would be necessary to maintain given indoor air concentrations. This in turn suggests that intrusion could remain a substantive problem for chronic exposure periods.

Calculations in support of the above analysis are provided in Appendix E.

7.4 Uncertainties Associated with Toxicity Assessment

A potentially large source of uncertainty is inherent in the derivation of the EPA toxicity criteria (i.e., RfDs, and cancer slope factors). In many cases, data must be extrapolated from animals to sensitive humans by the application of uncertainty factors to an estimated NOAEL or LOAEL for non-cancer effects. While designed to be protective, it is likely in many cases that uncertainty factors overestimate the magnitude of differences that may exist between human and animals, and among humans.

In some cases, however, toxicity criteria may be based on studies that did not detect the most sensitive adverse effects. For example, many past studies have not measured possible toxic effects on the immune system. Moreover, some chemicals may cause subtle effects not easily recognized in animal studies. The effects of lead on cognitive function and behavior at very low levels of exposure serve as examples.

In addition, derivation of cancer slope factors often involves linear extrapolation of effects at high doses to potential effects at lower doses commonly seen in environmental exposure settings. Currently, it is not known whether linear extrapolation is appropriate. In all likelihood, the shape of the dose response curve for carcinogenesis varies with different chemicals and mechanisms of action. It is not possible at this time, however, to describe such differences in quantitative terms.

It is likely that the assumption of linearity is conservative and yields slope factors that are unlikely to lead to underestimation of risks. Yet, for specific chemicals, current methodology could cause slope factors, and, hence, risks, to be underestimated.

Use of CalEPA toxicity criteria could either over or underestimate potential risks, but it is difficult to determine either the direction or magnitude of any errors. In general, however, it is likely that the criteria err on the side of protectiveness for most chemicals.

Benzo(g,h,i)perylene in soil was the only chemical eliminated based on lack of toxicity criteria. Quantitative risks and hazards could not be calculated for this chemical in the absence of toxicity criteria. As such, this chemical was removed from the quantitative analysis. Omission of this chemical is unlikely to affect the outcome of the risk assessment. Although toxicity factors have not been identified for this chemical, USEPA has classified benzo(g,h,i)perylene as not being a human carcinogen. Studies verifying non-carcinogenic effects from exposure to benzo(g,h,i)perylene are not available at this time.

In August 2001, EPA released a health risk assessment for TCE that presents a new cancer slope factor range, $2E-02$ to $4E-01$ (mg/kg-day)⁻¹, which would result in calculated risk estimates two to 40 times greater than those calculated with OEHHA's slope factor for TCE, $1.3E-02$ (mg/kg-day)⁻¹. The revised cancer slope factor range was based on stronger epidemiological evidence than was available for previous assessments. In particular, several diverse studies including cancer estimates derived for kidney and liver cancer from occupational exposure, non-Hodgkin's lymphoma from exposure to drinking water and liver cancer in laboratory mice provide the basis for the quantitative assessment. Currently, under EPA's cancer guidelines TCE would be classified as a "probable human carcinogen" (group B1), with "limited" human evidence and "sufficient" animal evidence of carcinogenicity. Under EPA's proposed cancer guidelines, TCE can be characterized as "highly likely to produce cancer in humans".

EPA's online toxicity database, IRIS, currently does not list toxicity factors for TCE, instead indicating that the carcinogen assessment for this chemical has been withdrawn following further review. The OEHHA online toxicity database continues to list the oral slope factor of $1.3E-02$ (mg/kg-day)⁻¹ and inhalation slope factor of $7.0E-03$ (mg/kg-day)⁻¹ for TCE. These values were used for the evaluation of TCE exposure in this risk assessment.

As shown in the tables and figures in Section 6, PCE is the primary risk driver at the site, followed by TCE. If the proposed and now withdrawn EPA TCE cancer slope factors were used, TCE risk values could be 2 to 40 times greater than calculated in this assessment and would make TCE the primary risk driver. TCE toxicity is currently being reconsidered and any TCE slope factors that come out of this revision are likely to be different than those previously proposed. Since calculated risks already indicate unacceptable risks due to exposure to PCE, any future upward revision of TCE toxicity values would not change the overall outcome of the assessment. In addition, any mitigation measures designed to reduce inhalation exposure to PCE would reduce inhalation exposures to TCE as well.

As noted in Section 5, dermal absorption factors are not available for all COPCs. RAGS Part E guidance only provides factors for semi-volatile organics. Volatile organics are likely to vaporize when they come in to contact with the skin and exposure to these chemicals are better captured under the inhalation pathway. Dermal exposure to inorganics is highly dependent on the speciation of the inorganics, and further research is not yet available. Thus, because dermal exposures cannot be further characterized at this time, dermal exposures in this risk assessment may underestimate actual risks and hazards.

7.5 Uncertainties in Risk Characterization

The current and future land use of the site was assumed to be commercial/industrial. The possibility that this site would be redeveloped for residential use is remote. Its location, surrounded by commercial/residential businesses and next to a major arterial, make it undesirable and unlikely for residential development. In addition, although the zoning of the site in the Whittier Boulevard Specific Plan-Workplace

District allows for Live/Work units and multi-family housing, City representatives have stated that it is unlikely that the Omega property will be redeveloped for residential uses (Adams, 2007). Thus, the assumption of a commercial/industrial land use is reasonable and appropriate.

Also if the site were redeveloped, with the construction of new commercial/industrial facilities, the foundation of the new facilities would be new and would likely not have significant cracks (as assumed in the indoor vapor intrusion model) that would allow easy passage of soil vapors.

The risk assessment assumes that current concentrations of COPCs will remain constant into the future. Data are not available to verify the appropriateness of this assumption. However, risk calculations for indoor air (which appears to be the primary pathway of concern) were based on data collected from 2004 to 2006. A review of the PCE indoor air data collected during this time period (provided in Table 7-3) shows a general decreasing trend of PCE concentrations. As such, it is likely that the risks calculated in this assessment provide an overestimate of future risks as PCE concentrations may decrease in the future. Uncertainties associated with future concentrations need to be taken into account whenever the risk estimates provided in this assessment are used in risk management decisions. They are considered equally important as the numerical estimates in providing a characterization of risk at the site.

Finally, risks and hazards calculated for exposures to construction workers to COPCs in surface and subsurface soil are likely to be artificially high because of the inherent conservatism in models used to estimate EPCs. Risks and hazards associated with direct contact with surface and subsurface soil appear to be minimal.

Section 8

Summary and Conclusions

The primary findings and conclusions of this risk assessment are briefly summarized in this section. The following tasks were performed as part of this risk assessment:

- Examined the history of the Omega Chemical site in Whittier, CA, and identified types of chemicals used and likely release mechanisms for these chemicals to enter the environment
- Evaluated data collected to characterize the site and existing contamination and used the most recent of these data to select chemicals of potential concern (COPCs) and to calculate exposure point concentrations
- Analyzed the potential for exposure to COPCs at the site through an evaluation of people that might be exposed, exposure pathways that might result in significant contact between these people and COPCs, and identification of exposure parameters appropriate for quantifying exposure resulting from this contact.
- Identified appropriate toxicity criteria for site COPCs
- Estimated risk to current and potential future receptors (people) that might contact contamination
- Evaluated uncertainties in data, exposure, toxicity and risk characterization aspects of the risk assessment
- Calculated health-based remediation goals (site-specific PRGs) for use in remediation decisions for the site

Important results of the risk assessment that follow from the above assessments can be summarized as follows:

- Field investigations since 2004 provide a recent and complete site characterization. High confidence can be assigned to use of these data to select chemicals of potential concern and to estimate exposure point concentrations.
- Commercial/industrial land use is an appropriate assumption for future site use. The site has been used for such purpose since it was developed from agricultural land in the 1950's. In addition, City representatives have stated that it is unlikely that the former Omega Chemical property will be redeveloped for residential uses (Adams, 2007), although the zoning of the site in the Whittier Blvd. Specific Plan-Workplace District allows for Live/Work units and multi-family housing.
- Among receptors likely to be exposed to site-related contaminants, the highest cancer risks and noncancer hazards are associated with exposure of hypothetical

future residents, with risks above the EPA risk range and hazards above the target threshold.

- The pathway that suggests the highest potential for exposure involves intrusion of vapors into indoor air spaces. Inhalation of these vapors indoors results in the highest estimates of potential cancer risk and noncancer hazard.
- PCE is the primary COPC of concern at the site. For example, inhalation of indoor air suggests potential total inhalation cancer risks for current industrial workers ranging from $8E-6$ to $7E-5$. Cancer risk associated with inhalation exposure to PCE alone ranges from $5E-7$ to $4E-05$. Estimated hazards for PCE were relatively low, however. HQs for exposure to indoor air for PCE ranged from 0.01 to 1.6 compared to a total inhalation HIs ranging from 0.06 to 8.
- Total cancer risk estimates for future commercial/industrial indoor worker based on data from All Parcels (CTE, $9E-6$ to $3E-4$ and RME, $1E-5$ to $5E-4$) are above the EPA risk range (Table 6-2; Figure 6-8). Total cancer risk estimates for future commercial/industrial outdoor worker based on data from All Parcels (CTE, $1E-5$ to $2E-5$ and RME, $1E-5$ to $2E-5$) are above the point of departure of one in one million but within the EPA risk range. Cancer risks for the future industrial/commercial indoor worker are primarily attributable to inhalation of indoor air. PCE in soil gas accounts for 90 percent of the total inhalation risk. Cancer risks for future industrial/commercial outdoor worker are primarily attributable to exposure to COPCs in soil.
- Potential risks associated with exposure to ambient (urban background) concentrations of VOCs are as high as 3×10^{-5} and may account for 12 to essentially 100 percent of total risks estimated for indoor exposures, depending on parcel. LA Carts/Oncology Care may not be affected by site-related VOCs. Further, subsurface VOC contamination appears to be insufficient to sustain releases that would produce significant ambient air concentrations over extended periods of time.
- Ambient air risks for construction workers are within and near the lower end of the EPA risk range, and ambient air hazards are below the target threshold. Subsurface VOC contamination appears to be insufficient to sustain releases that would produce significant ambient air concentrations over the one-year time period assumed for construction worker exposures. .
- Hypothetical exposure to contaminants in soil is unlikely to occur, since soil is currently covered with buildings, asphalt, and concrete and such cover is likely to remain even if the site is redeveloped for other commercial/industrial purposes in the future. Even if the current property cover is replaced by green-belt type landscape, it is unlikely that contaminated soils would be exposed at the ground surface where direct contact (e.g., dermal contact or ingestion) could occur. Further, volatile COPCs, in particular PCE, acetone, and toluene, will not persist

in non-volatile form in soils exposed during excavation, and direct contact exposures (incidental ingestion and dermal contact) for construction worker exposures via these pathways are expected to be minimal. These VOCs along with benzo(a)pyrene were associated with the bulk of risks and hazards estimated for direct contact exposure to surface soils.

- Uncertainties in the risk assessment suggest that site-related risks have been adequately characterized to support risk management decisions. In fact, the database is biased toward source/release areas and likely overstates levels of contamination for the site as a whole.
- Site-related risks involving exposure to PCE vapors in indoor air appear to be adequately assessed using available site-specific data.
- Site-specific PRGs developed for PCE can be used upon approval by EPA with confidence in evaluating remedial alternatives, if the site is deemed by EPA to pose an unacceptable risk.

UCL Summaries

A-1.1 Surface Soil 0-2.2 feet

Summary of UCLs for All Parcels Soil 0-2.2 ft bgs

Chemical	Distribution	95 UCL mg/kg		Maximum mg/kg	Mean mg/kg	Statistic
1,2-DICHLOROBENZENE	Data are Non-parametric (0.05)	0.445046	Use 99% Chebyshev (Mean, Sd) UCL	0.5	0.13315625	UCL-NP
1,4-DIOXANE	Data are lognormal (0.05)	9.615725	Use 99% Chebyshev (MVUE) UCL	14	1.7349	95% UCL-T
2-METHYLNAPHTHALENE	Data are Non-parametric (0.05)	0.389356	Use 95% Chebyshev (Mean, Sd) UCL	0.54	0.187142857	UCL-NP
4,4'-DDD	Data are Non-parametric (0.05)	0.023528	Use 99% Chebyshev (Mean, Sd) UCL	0.032	0.00262	UCL-NP
4,4'-DDE	Data are Non-parametric (0.05)	0.173553	Use 99% Chebyshev (Mean, Sd) UCL	0.3	0.017155263	UCL-NP
4,4'-DDT	Data are Non-parametric (0.05)	0.106265	Use 99% Chebyshev (Mean, Sd) UCL	0.15	0.016071053	UCL-NP
ALUMINIUM	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	9830	9707.5	
ANTIMONY	Data are Non-parametric (0.05)	13.70949	Use 99% Chebyshev (Mean, Sd) UCL	18	4.385714286	UCL-NP
ARSENIC	Data follow gamma distribution (0.05)	6.046788	Use Approximate Gamma UCL	21	5.226388889	95% UCL-G
BARIUM	Data are Non-parametric (0.05)	161.5074	Use Student's-t UCL	230	150.5416667	UCL-NP
BENZO(A)ANTHRACENE	Data are Non-parametric (0.05)	1.930534	Use 99% Chebyshev (Mean, Sd) UCL	2.4	0.288	UCL-NP
BENZO(A)PYRENE	Data are Non-parametric (0.05)	0.755766	Use 95% Chebyshev (Mean, Sd) UCL	1.6	0.246153846	UCL-NP
BENZO(B)FLUORANTHENE	Data are Non-parametric (0.05)	0.485788	Use 95% Chebyshev (Mean, Sd) UCL	0.91	0.193076923	UCL-NP
BENZO(G,H,I)PERYLENE	Data are Non-parametric (0.05)	0.340116	Use 95% Chebyshev (Mean, Sd) UCL	0.5	0.160769231	UCL-NP
BENZYL ALCOHOL (PHENYLMETHANOL)	Data are Non-parametric (0.05)	2.432875	Use 95% Chebyshev (Mean, Sd) UCL	5.2	0.616666667	UCL-NP
BERYLLIUM	Data are Non-parametric (0.05)	0.508604	Use Student's-t UCL	0.75	0.478055556	UCL-NP
BIS(2-ETHYLHEXYL)PHTHALATE	Data are Non-parametric (0.05)	27.14903	Use 99% Chebyshev (Mean, Sd) UCL	51	3.264142857	UCL-NP
BUTYLBENZYL PHTHALATE	Data are Non-parametric (0.05)	0.901286	Use 95% Chebyshev (Mean, Sd) UCL	1.9	0.310714286	UCL-NP
CADMIUM	Data are Non-parametric (0.05)	1.340821	Use 95% Chebyshev (Mean, Sd) UCL	2.1	0.882794118	UCL-NP
CALCIUM	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	7170	6612.5	
CHROMIUM	Data are Non-parametric (0.05)	88.77216	Use 95% Chebyshev (Mean, Sd) UCL	360	39.93055556	UCL-NP
CHRYSENE	Data are Non-parametric (0.05)	4.730344	Use 99% Chebyshev (Mean, Sd) UCL	6	0.545571429	UCL-NP
COBALT	Data are Non-parametric (0.05)	9.512926	Use Student's-t UCL	16	8.954166667	UCL-NP
COPPER	Data are Non-parametric (0.05)	40.02014	Use Student's-t UCL	150	32.65277778	UCL-NP
DIELDRIN	Data are Non-parametric (0.05)	0.039782	Use 99% Chebyshev (Mean, Sd) UCL	0.05	0.004471429	UCL-NP
DIETHYL PHTHALATE	Data are Non-parametric (0.05)	0.263424	Use 95% Chebyshev (Mean, Sd) UCL	0.5	0.125923077	UCL-NP
DI-N-BUTYLPHTHALATE	Data are Non-parametric (0.05)	0.297497	Use 95% Chebyshev (Mean, Sd) UCL	0.5	0.148461539	UCL-NP
DI-N-OCTYL PHTHALATE (DIOCTYL PHTHALA	Data are Non-parametric (0.05)	0.294512	Use 95% Chebyshev (Mean, Sd) UCL	0.5	0.145	UCL-NP
ENDRIN	Data are Non-parametric (0.05)	0.027009	Use 99% Chebyshev (Mean, Sd) UCL	0.032	0.002784615	UCL-NP
FLUORANTHENE (IDRYL)	Data are Non-parametric (0.05)	0.373462	Use 95% Chebyshev (Mean, Sd) UCL	0.66	0.163785714	UCL-NP
IRON	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	23200	22650	
ISOPHORONE	Data are Non-parametric (0.05)	9.054049	Use 99% Chebyshev (Mean, Sd) UCL	9.9	0.953333333	UCL-NP
LEAD	Data are lognormal (0.05)	65.38021	Use H-UCL	890	55.71666667	95% UCL-T
MAGNESIUM	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	5575	5382.5	
MANGANESE	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	353	296	
MERCURY	Data are Non-parametric (0.05)	0.304026	Use 95% Chebyshev (Mean, Sd) UCL	0.85	0.145545455	UCL-NP
MOLYBDENUM	Data are normal (0.05)	3.384177	Use Student's-t UCL	4.2	2.926666667	95% UCL-N
NAPHTHALENE	Data are Non-parametric (0.05)	0.597195	Use 95% Chebyshev (Mean, Sd) UCL	1.2	0.215384615	UCL-NP
NICKEL	Assuming gamma distribution (0.05)	24.93461	Use Approximate Gamma UCL	55	22.50555556	95% UCL-G assumed
PCB-1254 (AROCLOR 1254)	Data are Non-parametric (0.05)	0.425054	Use 99% Chebyshev (Mean, Sd) UCL	0.5	0.063571429	UCL-NP
PHENANTHRENE	Data are Non-parametric (0.05)	3.693868	Use 99% Chebyshev (Mean, Sd) UCL	5	0.442866667	UCL-NP
POLYCHLORINATED BI PHENYLS, TOTAL	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	0.5	0.5	
POTASSIUM	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	4520	4435	
PYRENE	Data are Non-parametric (0.05)	2.314593	Use 99% Chebyshev (Mean, Sd) UCL	3.1	0.317466667	UCL-NP
SILVER	Data are Non-parametric (0.05)	0.645985	Use Student's-t UCL	1.2	0.556666667	UCL-NP
SODIUM	Too Few Observations To Calculate UCLs	No UCL	Too Few Observations To Calculate UCLs	320	305	
THALLIUM	Data are Non-parametric (0.05)	3.337258	Use 95% Chebyshev (Mean, Sd) UCL	3.5	2.415384615	UCL-NP
VANADIUM	Data are normal (0.05)	47.08547	Use Student's-t UCL	71	44.09722222	95% UCL-N

RECOMMENDATION
 Data are Non-parametric (0.05)
 Use Hall's Bootstrap UCL
 Use 99% Chebyshev (Mean, Sd) UCL

Recommended UCL exceeds the maximum o
 456.461

In case Hall's Bootstrap method yields
 an erratic, unreasonably large UCL value,
 use 99% Chebyshev (Mean, Sd) UCL

Exposure Variable	PbB Equation ¹		Description of Exposure Variable	Units	Values for Non-Residential Exposure Scenario			
	1*	2**			Using Equation 1		Using Equation 2	
					GSDi = Hom	GSDi = Het	GSDi = Hom	GSDi = Het
PbS	X	X	Soil lead concentration	ug/g or ppm	65.4	65.4	65.4	65.4
R _{fetal/maternal}	X	X	Fetal/maternal PbB ratio	--	0.9	0.9	0.9	0.9
BKSF	X	X	Biokinetic Slope Factor	ug/dL per ug/day	0.4	0.4	0.4	0.4
GSD _i	X	X	Geometric standard deviation PbB	--	2.1	2.3	2.1	2.3
PbB ₀	X	X	Baseline PbB	ug/dL	1.5	1.7	1.5	1.7
IR _S	X		Soil ingestion rate (including soil-derived indoor dust)	g/day	0.100	0.100	--	--
IR _{S+D}		X	Total ingestion rate of outdoor soil and indoor dust	g/day	--	--	0.100	0.100
W _S		X	Weighting factor; fraction of IR _{S+D} ingested as outdoor soil	--	--	--	1.0	1.0
K _{SD}		X	Mass fraction of soil in dust	--	--	--	0.7	0.7
AF _{S,D}	X	X	Absorption fraction (same for soil and dust)	--	0.12	0.12	0.12	0.12
EF _{S,D}	X	X	Exposure frequency (same for soil and dust)	days/yr	250	250	250	250
AT _{S,D}	X	X	Averaging time (same for soil and dust)	days/yr	365	365	365	365
PbB_{adult}	PbB of adult worker, geometric mean			ug/dL	1.7	1.9	1.7	1.9
PbB_{fetal,0.95}	95th percentile PbB among fetuses of adult workers			ug/dL	5.2	6.8	5.2	6.8
PbB_t	Target PbB level of concern (e.g., 10 ug/dL)			ug/dL	10.0	10.0	10.0	10.0
P(PbB_{fetal} > PbB_t)	Probability that fetal PbB > PbB_t, assuming lognormal distribution			%	0.6%	1.7%	0.6%	1.7%

¹ Equation 1 does not apportion exposure between soil and dust ingestion (excludes W_S, K_{SD}).

When IR_S = IR_{S+D} and W_S = 1.0, the equations yield the same PbB_{fetal,0.95}.

***Equation 1, based on Eq. 1, 2 in USEPA (1996).**

PbB_{adult} =	$(PbS * BKSF * IR_{S+D} * AF_{S,D} * EF_S / AT_{S,D}) + PbB_0$
PbB_{fetal,0.95} =	$PbB_{adult} * (GSD_i^{1.645} * R)$

****Equation 2, alternate approach based on Eq. 1, 2, and A-19 in USEPA (1996).**

PbB_{adult} =	$PbS * BKSF * [(IR_{S+D}) * AF_S * EF_S * W_S] + [K_{SD} * (IR_{S+D}) * (1 - W_S) * AF_D * EF_D] / 365 + PbB_0$
PbB_{fetal,0.95} =	$PbB_{adult} * (GSD_i^{1.645} * R)$

SITE RISK ASSESSMENT IDENTIFICATION INFORMATION
Omega Chemical Site - Whittier, California

Site Name/OU:	Omega Chemical Site
Region:	USEPA Region 9
EPA ID Number:	CAD042245001
State:	California
Status:	Remedial Investigation
Federal Facility (Y/N):	No
EPA Project Manager:	Christopher Lichens
EPA Risk Assessor:	Dr. Stan Smucker
Prepared by (Organization):	Camp Dresser & McKee Inc.
Prepared for (Organization):	Omega Chemical Site PRP Organized Group
Document Title:	Human Health Risk Assessment for On-Site Soils, Omega Chemical Superfund Site
Document Date:	November 2007
Probabilistic Risk Assessment (Y/N):	No
Comments:	

TABLE A3-1.0
SELECTION OF EXPOSURE PATHWAYS
Omega Chemical Site - Whittier, California

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Onsite/ Offsite	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway		
Current	Soil	Surface Soil	Soil at Omega Site from 0' to 2.2'	Industrial Worker - Indoors	Adult	Ingestion	Onsite	Quantitative	Current industrial workers may incidentally ingest surface soil		
						Dermal	Onsite	Quantitative	Current industrial workers may come into contact with surface soil		
		Subsurface Soil		Industrial Worker - Indoors	Adult	Inhalation	Onsite	None	Current industrial workers are not expected to inhale soil particulates, site is paved		
						Ingestion	Onsite	None	Current industrial workers are not expected to incidentally ingest subsurface soil		
						Dermal	Onsite	None	Current industrial workers are not expected to come into contact with subsurface soil		
	Soil Gas	Outdoor Air ⁽³⁾	Industrial Worker - Indoors	Adult	Inhalation	Onsite	Quantitative	Current industrial workers may be exposed to soil gas in outdoor air			
					Inhalation	Onsite	Quantitative	Current industrial workers may be exposed to soil gas in indoor air			
	Groundwater	Groundwater	Groundwater in Drinking Water	Industrial Worker - Indoors	Adult	Ingestion	Onsite	None - See Text ⁽²⁾	Current industrial workers are not expected to ingest groundwater from the site		
						Dermal	Onsite	None - See Text ⁽²⁾	Current industrial workers are not expected to come into contact with groundwater from the site		
						Inhalation	Onsite	None - See Text ⁽²⁾	Current industrial workers are not expected to inhale contaminants of groundwater origin		
Onsite							None - See Text ⁽²⁾	Current industrial workers are not expected to inhale contaminants of groundwater origin			
Future						Soil	Surface & Subsurface Soil regraded	Industrial Worker - Indoors	Adult	Ingestion	Onsite
	Dermal	Onsite	Quantitative	Future industrial workers may come into contact with soil							
	Inhalation	Onsite	Quantitative	Future industrial workers may inhale soil particulates, if site pavement is removed							
		Onsite	Quantitative	Future industrial workers may inhale soil particulates, if site pavement is removed							
	Industrial Worker - Outdoors	Adult	Ingestion	Onsite	Quantitative			Future industrial workers may incidentally ingest soil			
			Dermal	Onsite	Quantitative			Future industrial workers may come into contact with soil			
			Inhalation	Onsite	Quantitative			Future industrial workers may inhale soil particulates, if site pavement is removed			
				Onsite	Quantitative			Future industrial workers may inhale soil particulates, if site pavement is removed			
	Resident	Adult	Ingestion	Onsite	Quantitative			Future adult resident may incidentally ingest soil			
			Dermal	Onsite	Quantitative			Future adult resident may come into contact with soil			
			Inhalation	Onsite	Quantitative			Future adult resident may inhale soil particulates from soil			
				Onsite	Quantitative			Future adult resident may inhale soil particulates from soil			
	Adult/Child	Adult/Child	Ingestion	Onsite	Quantitative			Future adult/child resident may incidentally ingest soil			
			Dermal	Onsite	Quantitative			Future adult/child resident may come into contact with soil			
			Inhalation	Onsite	Quantitative			Future adult/child resident may inhale soil particulates from soil			
				Onsite	Quantitative			Future adult/child resident may inhale soil particulates from soil			
	Child	Child	Ingestion	Onsite	Quantitative			Future child resident may incidentally ingest soil			
			Dermal	Onsite	Quantitative			Future child resident may come into contact with soil			
			Inhalation	Onsite	Quantitative			Future child resident may inhale soil particulates from soil			
				Onsite	Quantitative			Future child resident may inhale soil particulates from soil			
	Construction Worker	Adult	Ingestion	Onsite	Quantitative	Future construction workers may incidentally ingest soil					
			Dermal	Onsite	Quantitative	Future construction workers may come into contact with soil					
			Inhalation	Onsite	Quantitative	Future construction workers may inhale soil particulates					
				Onsite	Quantitative	Future construction workers may inhale soil particulates					
	Soil Gas	Outdoor Air ⁽³⁾	Outdoor Air ⁽³⁾	Construction Worker	Adult	Inhalation	Onsite	Quantitative	Future construction workers may be exposed to soil gas 5' to 30' bgs in outdoor air		
						Inhalation	Onsite	Quantitative	Future construction workers may be exposed to soil gas 5' to 30' bgs in outdoor air		
				Resident	Adult	Inhalation	Onsite	None - See Text ⁽²⁾	Indoor air exposure will be more significant than outdoor air exposure, thus future adult resident is not evaluated for soil gas 5' to 6' bgs in outdoor air		
							Onsite	None - See Text ⁽²⁾	Indoor air exposure will be more significant than outdoor air exposure, thus future adult resident is not evaluated for soil gas 5' to 6' bgs in outdoor air		
						Adult/Child	Adult/Child	Inhalation	Onsite	None - See Text ⁽²⁾	Indoor air exposure will be more significant than outdoor air exposure, thus future adult/child resident is not evaluated for soil gas 5' to 6' bgs in outdoor air
									Onsite	None - See Text ⁽²⁾	Indoor air exposure will be more significant than outdoor air exposure, thus future adult/child resident is not evaluated for soil gas 5' to 6' bgs in outdoor air
				Industrial Worker - Outdoors	Adult	Inhalation	Onsite	Quantitative	Future industrial workers may be exposed to soil gas 5' to 6' bgs in outdoor air		
							Onsite	Quantitative	Future industrial workers may be exposed to soil gas 5' to 6' bgs in outdoor air		
		Inhalation	Onsite			Quantitative	Future industrial workers may be exposed to soil gas 5' to 6' bgs in indoor air				
			Onsite			Quantitative	Future industrial workers may be exposed to soil gas 5' to 6' bgs in indoor air				
		Indoor Air ⁽⁴⁾	Resident	Resident	Adult	Inhalation	Onsite	Quantitative	Future adult resident may be exposed to soil gas 5' to 6' bgs in indoor air		
							Onsite	Quantitative	Future adult resident may be exposed to soil gas 5' to 6' bgs in indoor air		
					Adult/Child	Adult/Child	Inhalation	Onsite	Quantitative	Future adult/child resident may be exposed to soil gas 5' to 6' bgs in indoor air	
								Onsite	Quantitative	Future adult/child resident may be exposed to soil gas 5' to 6' bgs in indoor air	
			Industrial Worker - Indoors	Adult	Industrial Worker - Indoors	Inhalation	Onsite	Quantitative	Future industrial workers may be exposed to soil gas in indoor air		
							Onsite	Quantitative	Future industrial workers may be exposed to soil gas in indoor air		
Ingestion	Onsite					None - See Text ⁽²⁾	Future industrial workers are not expected to ingest groundwater from the site				
	Onsite					None - See Text ⁽²⁾	Future industrial workers are not expected to ingest groundwater from the site				
Groundwater	Groundwater	Groundwater in Drinking Water	Industrial Worker - Indoors	Adult	Dermal	Onsite	None - See Text ⁽²⁾	Future industrial workers are not expected to come into contact with groundwater from the site			
					Inhalation	Onsite	None - See Text ⁽²⁾	Future industrial workers are not expected to inhale contaminants of groundwater origin			
						Onsite	None - See Text ⁽²⁾	Future industrial workers are not expected to inhale contaminants of groundwater origin			
					Industrial Worker - Outdoors	Adult	Ingestion	Onsite	None - See Text ⁽²⁾	Future industrial workers are not expected to ingest groundwater from the site	
			Onsite	None - See Text ⁽²⁾				Future industrial workers are not expected to ingest groundwater from the site			
			Inhalation	Onsite			None - See Text ⁽²⁾	Future industrial workers are not expected to come into contact with groundwater from the site			
				Onsite			None - See Text ⁽²⁾	Future industrial workers are not expected to come into contact with groundwater from the site			
			Resident	Adult/child	Ingestion	Onsite	None - See Text ⁽²⁾	Future residents are not expected to ingest groundwater from the site			
						Onsite	None - See Text ⁽²⁾	Future residents are not expected to ingest groundwater from the site			
					Inhalation	Onsite	None - See Text ⁽²⁾	Future residents are not expected to come into contact with groundwater from the site			
						Onsite	None - See Text ⁽²⁾	Future residents are not expected to come into contact with groundwater from the site			
			Construction Worker	Adult	Ingestion	Onsite	None - See Text ⁽²⁾	Future construction workers are not expected to incidentally ingest groundwater			
Onsite	None - See Text ⁽²⁾	Future construction workers are not expected to incidentally ingest groundwater									
Inhalation	Onsite	None - See Text ⁽²⁾			Future construction workers are not expected to come into contact with groundwater						
	Onsite	None - See Text ⁽²⁾			Future construction workers are not expected to come into contact with groundwater						

(1) Indoor air for current scenarios was evaluated using measured indoor air data for all parcels except for Skateland. The current Skateland building is slated for demolition, as such, soil gas result were used to evaluate this pathway on this parcel.
(2) Domestic use of groundwater risks are not evaluated in this analysis. They will be evaluated in EPA's Site-wide Risk Assessment.
(3) Future outdoor air risks for the construction worker were evaluated using measured soil gas concentrations from 5 to 12 feet bgs in the Johnson and Ettinger Model. For the other scenarios, measured outdoor air concentrations were used.
(4) Future indoor air risks were evaluated using measured soil gas concentrations from 5 to 6 feet bgs in the Johnson and Ettinger Model.
(5) Outdoor air for current scenarios was evaluated using measured outdoor air data.

TABLE A3-2.1 - Parcel Site
 OCCURRENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - Surface Soil
 Omega Chemical Site - Whittier, California

- (1) Detection limits for detected chemicals in historical data were not available.
 (2) Maximum detected concentration used for screening.
 (3) Maximum detected background concentration.
 (4) Screened against 1/10th EPA's Region 9 Preliminary Remediation Goals (PRGs) for industrial soil (EPA 2004c) to account for additivity of multiple chemicals.
 (5) Not available.
 (6) Chromium concentrations were divided between Chromium III and Chromium VI assuming a 1:6 ratio of Cr VI:Cr III
 (7) Rationale Codes.

- Definitions: NA: Not Available.
 ND: Not Detected.
 nc: Screening Toxicity Value is based on noncancer effects
 ca: Screening Toxicity Value is based on cancer effects.
 COPC: Chemical of Potential Concern
 ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered.
 VOCs: Volatile Organic Compounds
 ug/kg: microgram per kilogram.
 ca*: where nc PRG < 100X ca PRG
 ca**: where nc PRG < 10X ca PRG

Selection Reason:

- ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs

- NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen

Deletion Reason:

- BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 NTX1: Infrequent Detection and No Toxicity Information Available
 IFD: Infrequent Detection
 IFD1: Infrequent Detection and Below Screening Level
 STAT: Not a site contaminant according to separate statistical analysis. see text

- Detection limits for detected chemicals in historical data were not available.
- Maximum detected concentration used for screening.
- Maximum detected background concentration.
- Screened against 1/10th EPA's Region 9 Preliminary Remediation Goals (PRGs) for industrial soil (EPA 2004c) to account for additivity of multiple chemicals.
- Not available.
- Chromium concentrations were divided between Chromium III and Chromium VI assuming a 1:6 ratio of Cr VI:Cr III
- Rationale Codes:

Definitions: NA: Not Available.
 ND: Not Detected.
 nc: Screening Toxicity Value is based on noncancer effects.
 ca: Screening Toxicity Value is based on cancer effects.
 COPC: Chemical of Potential Concern.
 ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered
 VOCs: Volatile Organic Compounds.
 ug/kg: microgram per kilogram.
 ca*: where nc PRG < 100X ca PRG
 ca**: where nc PRG < 10X ca PRG

Selection Reason: ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs
 NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 NTX1: Infrequent Detection and No Toxicity Information Available
 IFD: Infrequent Detection
 IFD1: Infrequent Detection and Below Screening Level
 STAT: Not a site contaminant according to separate statistical analysis, see text

(1) Maximum detected concentration used for screening

(2) Maximum detected background concentration.

(3) Screened against 1/10th CalEPA's CHHSLs Indoor Air Screening Levels for Human Health Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.

(4) Rationale Codes:

Selection Reason ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs
 NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available

Definitions:

NA: Not Available.

ND: Not Detected.

nc: Screening Toxicity Value is based on noncancer effects.

ca: Screening Toxicity Value is based on cancer effects.

COPC: Chemical of Potential Concern.

ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered

ug/m³: microgram per cubic meter.

- (1) Maximum detected concentration used for screening.
 (2) Maximum detected background concentration.
 (3) Screened against 1/10th CalEPA's CHHSLs Indoor Air Screening Levels for Human Health Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.
 (4) Rationale Codes:

Definitions: NA: Not Available.
 ND: Not Detected.
 nc: Screening Toxicity Value is based on noncancer effects.
 ca: Screening Toxicity Value is based on cancer effects.
 COPC: Chemical of Potential Concern.
 ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered
 ug/m³: microgram per cubic meter.

Selection Reason: ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs
 NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen
 Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available

(1) Maximum detected concentration from onsite samples

(2) Maximum detected background concentration.

(3) Screened against 1/10th EPA's Shallow Soil Gas Screening Levels for Human Health (Vapor Intrusion) for Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.

(4) Rationale Codes:

Selection Reason: ASL: Above Screening Level

TOX: Chemical is a Class A Carcinogen

DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs

NSL: No Screening Level

FD: Frequent Detection

CARC: Infrequent Detection but Chemical is a Carcinogen

Deletion Reason: BSL: Below Screening Level

BSL1: Infrequent Detection and Below Screening Level

NUT: Essential Nutrient

NTX: No Toxicity Information Available

IFD: Infrequent Detection

Definitions:

NA: Not Available.

ND: Not Detected.

nc: Screening Toxicity Value is based on noncancer effects.

ca: Screening Toxicity Value is based on cancer effects.

COPC: Chemical of Potential Concern.

ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered

ug/m³: microgram per cubic meter.

(1) Maximum detected concentration from onsite samples

(2) Maximum detected background concentration.

(3) Screened against 1/10th EPA's Shallow Soil Gas Screening Levels for Human Health (Vapor Intrusion) for Commercial/Industrial Use (EPA 2005) to account for additivity of multiple chemicals.

(4) Rationale Codes:

Selection Reason: ASL: Above Screening Level
 TOX: Chemical is a Class A Carcinogen
 DET: Relatively few chemicals detected at site, so comparison with screening levels and frequency of detection were not used to eliminate COPCs

NSL: No Screening Level
 FD: Frequent Detection
 CARC: Infrequent Detection but Chemical is a Carcinogen

Deletion Reason: BSL: Below Screening Level
 BSL1: Infrequent Detection and Below Screening Level
 NUT: Essential Nutrient
 NTX: No Toxicity Information Available
 IFD: Infrequent Detection

Definitions:

NA: Not Available.

ND: Not Detected.

nc: Screening Toxicity Value is based on noncancer effects.

ca: Screening Toxicity Value is based on cancer effects.

COPC: Chemical of Potential Concern.

ARAR/TBC: Applicable or Relevant and Appropriate Requirement/To Be Considered ug/m³; microgram per cubic meter.

TABLE A3-3 1 - Parcel Site
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
Omega Chemical Site - Whittier, California

Scenario Timeframe:	Current
Medium:	Surface Soil 0' to 2.2'
Exposure Medium:	Surface Soil 0' to 2.2'

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean ⁽¹⁾	95% UCL of Distribution ⁽¹⁾	Maximum Detected Concentration	Exposure Point Concentrations			
						Value	Units	Statistic ⁽²⁾	Rationale
	THALLIUM	mg/kg	2.42	3.34	2	2.00	mg/kg	Max	UCL is greater than Max
	VANADIUM	mg/kg	44.10	47.09	71	47.09	mg/kg	95% UCL-N	
	ZINC	mg/kg	81.53	97.28	350	97.28	mg/kg	UCL-NP	

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

(2) The Shapiro-Wilk test was used to test the normality/ lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data.

NA: too few detections to calculate a UCL
mg/kg: milligram per kilogram.

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

The Shapiro-Wilk test was used to test the normality/ lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data.

(2) Soil gas values modeled to provide indoor air concentrations using EPA Advance Soil Gas Model using Johnson and Ettinger algorithms for Commercial Worker Exposure. See Appendix Table A4-1

ug/m³: microgram per cubic meter.

ND: Not determined. Indoor air concentration could not be calculated because physical parameters for constituent were not available.

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

The Shapiro-Wilk test was used to test the normality/ lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data.

(2) Soil gas values modeled to provide indoor air concentrations using Karami, et al. (1987) equations along with the USEPA Draft Soil Screening Guidance (1994) to estimate outdoor air concentrations from soil gas. See Appendix Tables A5-5 and A5-6.

ug/m³: microgram per cubic meter.

ND: Not determined. Indoor air concentration could not be calculated because physical parameters for constituent were not available.

Statistics: Maximum Detected Value (Max), 95% UCL of Normal Data (95% UCL-N); 95% UCL of Log-transformed Data (95% UCL-T); Non-parametric (UCL-NP); 95% UCL assuming Gamma distribution (95% G-UCL).

(1) The arithmetic mean and the 95UCL were calculated including half the detection limit for the non-detects. As a result, in some cases these values are above the maximum detected.

The Shapiro-Wilk test was used to test the normality/ lognormality of all data sets at the 0.05 significance level. The UCL procedures listed were selected based on the recommendations of the ProUCL statistical program and based on the results of the W Test, the number of samples, and the standard deviation of the log-transformed data

(2) Soil gas values modeled to provide outdoor air concentrations using Karami, et al. (1987) equations along with the USEPA Draft Soil Screening Guidance (1994). See Appendix Tables A5-9 and A5-10.

ug/m³: microgram per cubic meter.

ND: Not determined. Indoor air concentration could not be calculated because physical parameters for constituent were not available.

- (1) Outdoor worker exposure parameter was conservatively applied to this receptor.
 (2) Residential exposure parameter was conservatively applied to this receptor.
 (3) Assumes 3 days/week in the spring and fall and 5 days/week in the summer, with 13 weeks per season.
 (4) Based on number of years in the age group for adolescents (ages 12 to 18 years).
 (5) Assumes mowing lawn 1 day/week, May through October.
 (6) Based on 50th percentile values for men and women (EPA 1997a) for the following body parts: head, hands, and forearms.
 (7) Based on 50th percentile total body surface area for 12 to 18 year olds (EPA 1997a, p6-15) and mean percentage for the following body parts: head, hands, forearms, and lower legs (EPA 1997a, p. 6-16).
 (8) AF was selected based on adolescent in dry soil for 95% percentile value.
 * Utility worker assumptions were conservatively selected as equal to construction worker exposure assumptions unless noted as being based upon "professional judgment."

(1) EPA 2004. Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Ju Exhibit 3-4 "—" signifies that no dermal absorption fraction from soil was provided. VOCs are assumed to volatilize and are accounted for in the inhalation pathway and are highly dependent on the speciation of the compound and there is too little data to determine a reasonable default value.

(2) ABS_d values for 1,4-dioxane, bromoform, benzyl alcohol, dieldrin, DDE, DDD, isophorone, and xylenes were obtained from EPA 2004 Region 9 PRG Table.

(3) EPA 2004. Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Ju Exhibit 4-1. Default value of 1 signifies that compound was not recommended for adjustment for gastrointestinal absorption efficiencies.

Footnotes:

(1) Dermal absorption adjustment is a combination of the dermal absorption fraction (ABSd) and the gastrointestinal absorption (ABSGI) as presented in Table A3-4.2. = ABSGI/ABSd so the absorbed reference dose = RfDo * ABSGI/ABSd

EPA-NCEA: USEPA Region III Provisional Peer Reviewed Toxicity Values for Superfund (PPRTV) (EPA 2005b).

HEAST: Health Effects Assessments Summary Tables (EPA 1997b).

IRIS: Integrated Risk Information System (EPA 2005a).

na: Chemical is listed, no value is available.

ni: No information available.

nl: Chemical is not listed.

CNS: Central Nervous System

mg/kg/day: milligram per kilogram per day.

ZINC	NA	mg/kg/day ⁻¹	NA	NA	mg/kg/day ⁻¹	D	IRIS	07/24/2007

Footnotes:

(1) Dermal absorption adjustment is a combination of the dermal absorption fraction (ABSd) and the gastrointestinal absorption (ABSGI) as presented in Table A3-4.2. = ABSGI/ABSd so the absorbed cancer slope factor = SFo * ABSd/ABSGI

(2) OEHHA considers naphthalene to be a carcinogen by inhalation only, therefore, the oral cancer slope factor is not used in this risk assessment.

EPA-NCEA: USEPA Region III Provisional Peer Reviewed Toxicity Values for Superfund (PPRTV) (EPA 2005b).

IRIS: Integrated Risk Information System (EPA 2005a).

na: Chemical is listed, no value is available.

ne: Chemical has not been evaluated by EPA for evidence of human carcinogenicity.

ni: No information available.

mg/kg/day⁻¹: milligram per kilogram-day

TABLE A3-7.1A - Parcel Site - 3 Kings Construction, CTE, Maximum Indoor Air Concentrations
CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS

Central Tendency Exposure

Omega Chemical Site - Whittier, California

Scenario Timeframe:	Current
Receptor Population:	Industrial Worker
Receptor Age:	Adult

Cancer Intake

Surface Soil	
Ingestion:	1.7E-07
Dermal:	2.3E-06
Inhalation of outdoor air	4.2E-03
Inhalation of soil vapor:	3.4E-02

Noncancer Intake

Surface Soil	
Ingestion:	4.9E-07
Dermal:	6.5E-06
Inhalation of outdoor air	1.2E-02
Inhalation of soil vapor:	9.4E-02

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day¹: milligram per kilogram-day.

TABLE A3-7 1A - Parcel Site - 3 Kings Construction, CTE, Minimum Indoor Air Concentrations
 CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS
 Central Tendency Exposure
 Omega Chemical Site - Whittier, California

Scenario Timeframe:	Current
Receptor Population:	Industrial Worker
Receptor Age:	Adult

Cancer Intake

Surface Soil	
Ingestion:	1.7E-07
Dermal:	2.3E-06
Inhalation of outdoor air	4.2E-03
Inhalation of soil vapor:	3.4E-02

Noncancer Intake

Surface Soil	
Ingestion:	4.9E-07
Dermal:	6.5E-06
Inhalation of outdoor air	1.2E-02
Inhalation of soil vapor:	9.4E-02

Medium	Exposure Medium	Exposure Point	Exposure Route	Chemical of Potential Concern	EPC		Cancer Risk Calculations					Non-Cancer Hazard Calculations				
					Value	Units	Intake/ Exposure Concentration		CSF	Cancer Risk	Intake/ Exposure Concentration		RfD		Hazard Quotient

										Total of Receptor Risks Across All Media		3.7E-07	Total of Receptor Hazards Across All Media			1.3E-01

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day¹: milligram per kilogram-day.

CTE: central tendency exposure

Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day¹: milligram per kilogram-day.

CTE: central tendency exposure

Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day

mg/kg/day¹: milligram per kilogram-day.

CTE: central tendency exposure

Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples

were collected between 10 and 12 ft bgs

ND: Not Detected.

NS: Not selected as an exposure pathway

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day¹: milligram per kilogram-day.

CTE: central tendency exposure

Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples

were collected between 10 and 12 ft bgs

										Total of Receptor Risks Across All Media	2.0E-06			Total of Receptor Hazards Across All Media		1.1E+00

ND: Not Detected.
 NS: Not selected as an exposure pathway.
 na: The chemical is listed, value is not available.
 ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.
 mg/kg: milligram per kilogram.
 mg/kg/day: milligram per kilogram per day.
 mg/kg/day⁻¹: milligram per kilogram-day.

RME: reasonable maximum exposure
 Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

--: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day¹: milligram per kilogram-day.

RME: reasonable maximum exposure

Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

TABLE A3-7.4B - Site Parcel, RME, Minimum Indoor Air Concentrations
 CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS
 Reasonable Maximum Exposure
 Omega Chemical Site - Whittier, California

Scenario Timeframe: Future
 Receptor Population: Construction Worker - RME
 Receptor Age: Adult

Cancer Intake

Surface Soil

Ingestion: 4.6E-08
 Dermal: 1.7E-07
 Inhalation of fugitive dust: 4.9E-12
 Inhalation of out. air in exc.: 6.7E-03
 Inhalation of outdoor air: 6.7E-03

Noncancer Intake

Surface Soil

Ingestion: 3.2E-06
 Dermal: 1.2E-05
 Inhalation of fugitive dust: 3.5E-10
 Inhalation of out. air in exc.: 4.7E-01
 Inhalation of outdoor air: 4.7E-01

				Exposure Point Total							Minimum	7.7E-09					Minimum	1.6E-03		
Soil gas - Ambient Air Total																	Minimum	1.6E-03		
Total of Receptor Risks Across All Media																				1.2E-06
Total of Receptor Hazards Across All Media																				8.1E-01

ND: Not Detected.
 NS: Not selected as an exposure pathway.
 na: The chemical is listed, value is not available.
 ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.
 mg/kg: milligram per kilogram.
 mg/kg/day: milligram per kilogram per day.
 mg/kg/day⁻¹: milligram per kilogram-day.

RME: reasonable maximum exposure
 Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

				Total of Receptor Risks Across All Media								1.2E-06	Total of Receptor Hazards Across All Media			8.1E-01

ND: Not Detected.
 NS: Not selected as an exposure pathway.
 na: The chemical is listed, value is not available.
 ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.
 mg/kg: milligram per kilogram.
 mg/kg/day: milligram per kilogram per day.
 mg/kg/day¹: milligram per kilogram-day.

RME: reasonable maximum exposure
 Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

Total of Receptor Risks Across All Media										4.3E-05	Total of Receptor Hazards Across All Media				4.1E+00	

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day¹: milligram per kilogram-day.

TABLE A3-7.7B - Parcel Other than Omega Site - RME, Maximum Indoor Air Concentrations
CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS

Reasonable Maximum Exposure
Omega Chemical Site - Whittier, California

Scenario Timeframe:	Future
Receptor Population:	Resident
Receptor Age:	Child

Cancer Intake

Surface Soil

Ingestion:	1.1E-06
Dermal:	3.2E-06
Inhalation of fugitive dust	4.1E-11
Inhalation of soil vapor:	5.5E-02

Noncancer Intake

Surface Soil

Ingestion:	1.3E-05
Dermal:	3.7E-05
Inhalation of fugitive dust	4.7E-10
Inhalation of soil vapor:	6.4E-01

Soil Gas - Outdoor Air Total											Maximum	1.1E-06		Maximum		1.6E-02	
Total of Receptor Risks Across All Media											4.7E-04	Total of Receptor Hazards Across All Media					6.9E+00

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day⁻¹: milligram per kilogram-day.

Soil Gas - Outdoor Air Total							Maximum 7.7E-06					Maximum 1.1E-01					
Total of Receptor Risks Across All Media											1.8E-05		Total of Receptor Hazards Across All Media				3.4E-01

ND: Not Detected.

NS: Not selected as an exposure pathway.

na: The chemical is listed, value is not available.

ne: The compound has not been evaluated by EPA for evidence of human carcinogenicity.

---: Risk was not calculated for chemical.

mg/kg: milligram per kilogram.

mg/kg/day: milligram per kilogram per day.

mg/kg/day⁻¹: milligram per kilogram-day.

TABLE A3-7.10 - All Parcels, CTE, Minimum Outdoor Air Concentrations
 CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS
 Central Tendency Exposure
 Omega Chemical Site - Whittier, California

Scenario Timeframe:	Future
Receptor Population:	Industrial Worker - Outdoors
Receptor Age:	Adult

Cancer Intake		Noncancer Intake	
Surface and Subsurface Soil		Surface and Subsurface Soil	
Ingestion:	3.1E-07	Ingestion:	8.8E-07
Dermal:	2.1E-06	Dermal:	5.8E-06
Inhalation of soil particulates:	3.5E-11	Inhalation of soil particulates:	9.8E-11
Inhalation of outdoor air:	4.8E-02	Inhalation of outdoor air:	1.3E-01
Inhalation of soil vapor:		Inhalation of soil vapor:

TABLE A3-7.11 - All Parcels, RME, Minimum Outdoor Air Concentrations
 CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS
 Reasonable Maximum Exposure
 Omega Chemical Site - Whittier, California

Scenario Timeframe:	Future
Receptor Population:	Industrial Worker - Outdoors
Receptor Age:	Adult

Cancer Intake

Surface and Subsurface Soil

Ingestion: 4.7E-07
 Dermal: 2.1E-06
 Inhalation of soil particulates 4.6E-11
 Inhalation of outdoor air 6.3E-02
 Inhalation of soil vapor:

Noncancer Intake

Surface and Subsurface Soil

Ingestion: 1.3E-06
 Dermal: 5.8E-06
 Inhalation of soil particulates 1.3E-10
 Inhalation of outdoor air 1.8E-01
 Inhalation of soil vapor:

Receptor Total							3.7E-07					1.3E-01

Total Risk Across All Media =

4E-07

Total Hazard Across All Media =

1.3E-01

NA Not applicable.

---: Risk was not calculated for chemical. Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples

HI: Hazard Index. were collected between 10 and 12 ft bgs

CNS: Central Nervous System.

CTE: central tendency exposure

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media.

Hazards by Toxicity Endpoint(1)

Total Liver HI Across All Media =

4.0E-02

Total Body Weight effects Across All Media =

3.9E-04

Total Kidney HI Across All Media =

2.7E-04

Total Other HI Across All Media =

		Exposure Point Total				Minimum	9.7E-10				Minimum	2.0E-04
		Exposure Medium Total				Minimum	9.7E-10				Minimum	2.0E-04
Soil Gas - Outdoor Air Total						Minimum	9.7E-10				Minimum	2.0E-04
Receptor Total							2.4E-07					7.8E-02

Total Risk Across All Media = 2E-07

Total Hazard Across All Media = 7.8E-02

NA: Not applicable.

---: Risk was not calculated for chemical. Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples were collected between 10 and 12 ft bgs

HI: Hazard Index.

CNS: Central Nervous System.

CTE: central tendency exposure

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media.

Hazards by Toxicity Endpoint(1)

Total Liver HI Across All Media = 1.7E-03

Total Body Weight effects Across All Media = 3.3E-04

Total Kidney HI Across All Media = 2.6E-04

Total Other HI Across All Media = 7.6E-02

Total Risk Across All Media =

1E-06

Total Hazard Across All Media =

8.1E-01

NA: Not applicable.

---: Risk was not calculated for chemical. Note: The 0 to 12 ft bgs soil dataset is the same as the 0 to 10 ft bgs dataset as no additional samples

HI: Hazard Index. were collected between 10 and 12 ft bgs

CNS: Central Nervous System

RME: reasonable maximum exposure

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media

Hazards by Toxicity Endpoint(1)

Total Liver HI Across All Media =

#VALUE!

Total Body Weight effects Across All Media =

4.2E-03

Total Kidney HI Across All Media =

2.9E-03

Total Other HI Across All Media =

7.9E-01

Total Hazard Across All Media =

7.4E+01

NA: Not applicable.

---: Risk was not calculated for chemical.

HI: Hazard Index

CNS: Central Nervous System.

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media.

Hazards by Toxicity Endpoint(1)

Total Liver HI Across All Media =

6.7E+01

Total Body Weight effects Across All Media =

2.3E-02

Total Kidney HI Across All Media =

2.3E-02

Total Other HI Across All Media =

7.2E+00

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media.

Total Risk Across All Media =

1.2E-05

Total Hazard Across All Media =

2.7E-01

NA: Not applicable.

---: Risk was not calculated for chemical.

HI: Hazard Index.

CNS: Central Nervous System.

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media.

Hazards by Toxicity Endpoint(1)

Total Liver HI Across All Media =

9.0E-03

Total Body Weight effects Across All Media =

1.3E-03

Total Kidney HI Across All Media =

9.3E-04

Total Other HI Across All Media =

2.6E-01

HI Hazard Index

CNS Central Nervous System

(1) When the total non-cancer hazard index is greater than one, the hazard index should be evaluated by totalling the hazard quotients for each toxicity endpoint and then comparing the total by organ to the target threshold of one. The totals below summarize the hazard quotients by primary target organs across all media.

- (1) Assumed an average soil temperature of 19.4oC per Figure A-1 in DTSC Indoor Air Guidance (Feb. 2005)
- (2) Assumed the soil was loam.
- (3) Exposure frequency and duration of 250 days per year and 25 years typical for a commercial worker and exposure time of 8 hrs/day.
- (4) Default building size of 10 meters length, 10 meters width, and 9-foot (276 cm) ceiling height was used.
- (5) Building air exchange for commercial business of 1 per hour.

- (1) Assumed an average soil temperature of 19.4oC per Figure A-1 in DTSC Indoor Air Guidance (Feb. 2005)
- (2) Assumed the soil was loam.
- (3) Default exposure frequency and duration of 350 days per year and 30 years typical for a resident and exposure time of 24 hrs/day.
- (4) Default building size of 10 meters length, 10 meters width, and 8-foot (244 cm) ceiling height was used.
- (5) Building air exchange for resident home of 0.5 per hour.

(1) Vapor diffusion coefficients from PRG physical Chemical parameters page - Di values.

(2) Apparent diffusion coefficient calculated from the following equation: $D_s = D_o (P_a^{1003}/P_t^2)$

(3) Flux calculated from the following equation from Karami, et al. (1987): $J = -D_s \cdot \frac{C_s}{L}$ (Assumes Cair to be very small)

(4) Emission rate calculated from the following equation: $E = J \times A_{site}$

(5) Flow estimate calculated from the following equation: $F = E/C_s$

(6) Ambient air concentration calculated from the following box equation: $C_{air} = E/(L_s \times W \times D_H)$

ug/m³ = micrograms per cubic meter

kg/m³ = kilograms per cubic meter

kg/m²/s = kilograms per square meter per second

m²/s = square meters per second

m³/s = cubic meters per second

m² = square meters

Parameter	Symbol	Value	Units	Comment

(1) Vapor diffusion coefficients from PRG physical Chemical parameters page - Di values.

(2) Apparent diffusion coefficient calculated from the following equation: $D_s = D_o (P_a^{1003}/P_t^2)$

(3) Flux calculated from the following equation from Karami, et al. (1987): $J = -D_s \cdot \Delta C_s/L$ (Assumes Cair to be very small)

(4) Emission rate calculated from the following equation: $E = J \times A_{site}$

(5) Flow estimate calculated from the following equation: $F = E/C_s$

(6) Ambient air concentration calculated from the following box equation: $C_{air} = E/(L_w \times W \times D_w)$

ug/m³ = micrograms per cubic meter

kg/m³ = kilograms per cubic meter

kg/m²/s = kilograms per square meter per second

m²/s = square meters per second

m³/s = cubic meters per second

m² = square meters

- (1) Vapor diffusion coefficients from PRG physical Chemical parameters page - Di values.
- (2) Apparent diffusion coefficient calculated from the following equation: $D_s = D_o (P_a^{100}/P_i^2)$
- (3) Flux calculated from the following equation from Karami, et al. (1987): $J = -D_s \cdot C_s/L$ (Assumes Cair to be very small)
- (4) Emission rate calculated from the following equation: $E = J \times A_{site}$
- (5) Flow estimate calculated from the following equation: $F = E/C_s$
- (6) Ambient air concentration calculated from the following box equation: $C_{air} = E/(L_s \times W \times D_H)$

ug/m³ = micrograms per cubic meter
 kg/m³ = kilograms per cubic meter
 kg/m²/s = kilograms per square meter per second
 m²/s = square meters per second
 m³/s = cubic meters per second
 m² = square meters

Parameter	Symbol	Value	Units	Comment
Air Filled Porosity	Pa	0.251		calculated from Equation in SSL Guidance: Pa = Pt - Ps
Water Filled Porosity	Ps	0.148		J&E model value for loam
Total Porosity	Pt	0.399		J&E model value for loam
Depth of Soil Layer	L	1.524	m	5 feet
Length of Side	Ls	10	m	10 m by 10 m subsurface foundation area excavation
Width (wind speed of 1.65 m/s)	V	0.165	m/s	Assume 1/10th the surface wind speed from http://www.whittier-weather.com/ (average wind speed of Whittier as 3.7 mi/hr = 1.65 m/s)
Diffusion Height	DH	2	m	Breathing zone
Site Area	A _{site}	100	m ²	10 m by 10 m subsurface foundation area excavation

Subject: Omega Chemical site - Future Land Uses

Hi Sharon,

Dave forwarded your email to me regarding the Omega site. Based on your question (see below) I would generally agree. I might change it to just "unlikely" since Live/Work units and multi-family residential are allowed uses within the Whittier Blvd. Specific Plan – Workplace District. However, based on information from the Director of Community Development we are looking for white collar, technical jobs in this area, such as office, biotech and medical uses. Hopefully this helps. Please call me at (562) 464-3580 if you have any questions.

Regards,

Jeff Adams

Planning Services Manager

City of Whittier

"we have stated that it is highly unlikely that the City would allow the property to be redeveloped for residential uses."

Appendix D

Appendix D

Site-Specific PRG Calculations

The results of the risk assessment calculations can be used to develop a series of preliminary remediation goals (PRGs) that can assist in managing site-related risks. PRGs are concentrations of chemicals of concern (COCs) in various media that, if achieved, would reduce site-related risks to acceptable levels. A series of site-specific PRGs were calculated for each set of receptors, pathways and chemicals where cancer risks exceeded $1E-07$ and/or HQs exceeded 0.1. These targets were selected to account for potential exposure to multiple chemicals, even though the results of the risk assessment indicate that nearly all of the unacceptable risk is accounted for through exposure to PCE.

No attempt was made to determine which combinations of receptors, pathways and chemicals would be most useful. Thus, PRGs are presented for construction workers, even though the risks from exposure of workers indoors are much higher and seem likely to form the basis for risk management. Generic PRGs (e.g. EPA Region 9 PRG tables) were not considered because they do not include values for soil gas, the only major contributor to site-related risks for the Omega site.

Health based risk goals (site-specific PRGs) can be used as guidelines to screen chemical concentrations in media for potential risks. Site-specific PRGs conform to EPA Risk Assessment Guidance for Superfund Volume 1, Part B (1991a). They do not automatically represent remediation levels nor do they establish that cleanup action to meet these site-specific PRGs is warranted (EPA 1991). Remediation levels to be used in cleanup activities are selected by the remedial project manager (RPM) following review of site-specific and other considerations, such as availability of data, regional information, uncertainties, and future site use. Action levels may reasonably be selected from the ranges of site-specific PRGs presented in this report.

The City intends to allow redevelopment that consists of commercial and retail uses with the construction of multi-level buildings. City representatives have stated that it is unlikely that the Omega property will be redeveloped for residential uses (Adams, 2007), although the zoning of the site as the Whittier Boulevard Specific Plan-Workplace District allows for Live/Work units and multi-family housing. Therefore, site-specific PRGs are developed for carcinogenic and noncarcinogenic risks for both residential and industrial receptors.

Site-specific PRGs were calculated only for those COPCs that had individual cancer risks above 10^{-7} or a hazard quotient above 0.1. This subset of COPCs are termed COCs and are likely most important for risk management. Results of the risk assessment, however, show that addressing PCE alone will address most site-related risk. Site-specific PRGs were calculated for soil, indoor air, ambient air, and soil gas.

To calculate site-specific PRGs, target cancer risks or HIs are input to the equations for back calculation to a media concentration. Thus, development of site-specific PRGs is basically the reverse of risk calculation. These calculations use a selected acceptable risk (i.e., a cancer risk of one in one million, 10^{-6} , and a hazard index of 1), exposure variables, and chemical toxicity factors to determine medium-specific chemical concentration instead of starting with measured concentrations and estimating risks. Exposure variables used in the calculations are the same as those presented in Table 4-2 and toxicity values are the same as those presented in Section 5. Media of concern, COPCs, receptor populations, potential exposure pathways and exposure assumptions for receptors were defined in Section 4. Site-specific PRG equations were modified from PRG equations in USEPA Region 9 PRG Guidance (USEPA 2004) and are provided below.

Equation for Exposure to Carcinogenic Contaminants in Industrial Soil through Ingestion, Dermal Contact, and Inhalation of Fugitive Dust

$$C_s \text{ (mg/kg)} = \frac{TR \times BW \times AT_c}{EF \times ED \left[\left(\frac{IR \times CSF}{10^6 \text{ mg/kg}} \right) + \left(\frac{SA \times AF \times ABS \times CSF}{10^6 \text{ mg/kg}} \right) + \left(\frac{ET \times IHR \times CSF}{PEF} \right) \right]}$$

Equation for Exposure to Noncarcinogenic Contaminants in Industrial Soil through Ingestion, Dermal Contact, and Inhalation of Fugitive Dust

$$C_s \text{ (mg/kg)} = \frac{THQ \times BW \times AT_n}{EF \times ED \left[\left(\frac{1}{RfD} \times \frac{IR}{10^6 \text{ mg/kg}} \right) + \left(\frac{1}{RfD} \times \frac{SA \times AF \times ABS}{10^6 \text{ mg/kg}} \right) + \left(\frac{1}{RfD} \times \frac{ET \times IHR}{PEF} \right) \right]}$$

Equation for Inhalation Exposure to Carcinogenic Contaminants in Indoor or Outdoor Air

$$C_a \text{ (ug/m}^3\text{)} = \frac{TR \times BW \times AT_c \times 1000 \text{ ug/mg}}{EF \times ED \times IHR \times ET \times CSF}$$

Equation for Inhalation Exposure to Noncarcinogenic Contaminants in Indoor or Outdoor Air

$$C_a \text{ (ug/m}^3\text{)} = \frac{THQ \times RfD \times BW \times AT_n \times 1000 \text{ ug/mg}}{EF \times ED \times IHR \times ET}$$

Where

- TR = Target Risk (a cancer risk of one in one million, 10⁻⁶)
- THQ = Target Hazard Quotient (a hazard index of 1)
- C_s = Chemical Concentration in Soil or Dust (mg/kg)
- C_a = Chemical Concentration in Air (mg/m³)
- IR = Ingestion Rate (mg/day)
- IhR = Inhalation Rate (m³/hour)
- PEF = Particulate Emission Factor (m³/kg)
- SA = Skin surface area exposed (cm²)
- AF = Soil to skin adherence factor (mg/cm²)
- ABS = Absorption fraction of chemical from soil
- ET = Exposure Time (hrs/day)
- EF = Exposure Frequency (days/year)
- ED = Exposure Duration (years)
- BW = Body Weight (kg)
- AT_c = Averaging Time - carcinogenic (days)
- AT_n = Averaging Time - noncarcinogenic (days)

For the adult+child scenario, the ingestion rate, skin contact and inhalation rates are time-weighted averages to account for different exposure assumptions used for adult and child receptors using the following equations:

Adjusted Ingestion Rate for Adult+Child

$$IR_{adj} (mg - yr/kg - d) = \frac{ED_c \times IR_c}{BW_c} + \frac{ED_a \times IR_a}{BW_a}$$

Adjusted Skin Contact Rate for Adult+Child

$$SA_{adj} (mg - yr/kg - d) = \frac{ED_c \times AF \times SA_c}{BW_c} + \frac{ED_a \times AF \times SA_a}{BW_a}$$

Adjusted Inhalation Rate for Adult+Child

$$IhR_{adj} (mg - yr/kg - d) = \frac{ED_c \times ET \times IhR_c}{BW_c} + \frac{ED_a \times ET \times IhR_a}{BW_a}$$

These equations were used to calculate exposure concentrations in primary exposure media. A target cancer risk of one in one million (10⁻⁶) and target hazard index of 1 were used for the calculation of site-specific PRGs as these threshold values were identified as the point of departure in the risk calculations. Site-specific PRGs for soil do not include inhalation of volatile compounds measured in soil which then partition to soil gas and are subsequently released to air. Inhalation of VOCs is captured primarily through exposure to soil gas, which is evaluated separately below. Should site-specific PRGs for soil be needed, they can be calculated during preparation of the FS using the methods used in the forward risk assessment.

For inhalation of VOCs in indoor and ambient air the primary exposure medium is soil gas. Exposure is assumed to occur after release of VOCs from this medium to indoor and ambient air. Remediation, if necessary for the site, would address soil gas (e.g. via soil vapor extraction). Thus, PRGs based on soil gas are necessary.

Site-specific risks for VOCs were calculated using a series of steps to estimate indoor or ambient air concentrations starting with soil gas concentrations, then using standard equations to estimate exposure and risk. Site-specific PRGs for soil gas were estimated by using the same attenuation factors that were used in the site-specific Johnson and Ettinger modeling. (Also, note that the advanced Johnson and Ettinger model for soil gas does not provide the option for calculating a PRG -- this feature is only available in the Johnson and Ettinger models for soil and groundwater.) Thus, site-specific PRGs for soil gas were calculated using the following equations.

Equation for Inhalation Exposure to Carcinogenic Contaminants in Indoor or Outdoor Air from Soil Gas

$$C_a (ug/m^3) = \frac{TR \times BW \times AT_c \times 1000ug / mg}{EF \times ED \times IhR \times ET \times CSF \times ATF}$$

Equation for Inhalation Exposure to Noncarcinogenic Contaminants in Indoor or Outdoor Air from Soil Gas

$$C_a (ug/m^3) = \frac{THQ \times RfD \times BW \times AT_n \times 1000ug / mg}{EF \times ED \times IhR \times ET \times ATF}$$

Where all variables are the same as listed previously, except:

ATF = Chemical-specific soil-gas-to-indoor or-outdoor-air attenuation factor,
which
= Calculated indoor or outdoor air concentration/measured soil gas
concentration

The calculation of soil gas site-specific PRGs is provided in Tables D-3.1 through D-3.6. As indicated above, corresponding bulk soil concentrations from the site-specific PRGs for soil gas were not calculated. These may be calculated in the feasibility study if later deemed necessary.

Site-specific PRGs calculated for the site are summarized in Tables D-4.1 and D-4.2 with full calculations provided in the earlier Tables D-1.1 through D-1.9 and D-2.1 through D-2.9.

Exposure assumptions and calculations did not vary among parcels, thus site-specific PRGs for indoor air are applicable for all buildings at the site currently, and for any buildings that may be constructed in the future. Likewise, although soil data were limited to the Omega site and its boundaries, exposure assumptions and calculations would be the same for surrounding parcels. Thus, site-specific PRGs for soil are also applicable to all parcels. A comparison of site-specific PRGs to maximum detections at each building is provided in Table D-5.

NA: Not applicable, not a COC for the pathway or the receptor scenario, chemicals were selected as COCs for the receptor only if the individually calculated risks were greater than 10⁻⁷ or the hazard greater than 0.1.

OK: indicates that HBRG is higher than screening level

CHHSL: California Human Health Screening Level

PRG: Preliminary Remediation Goal

ug/m³: microgram per cubic meter.

Bold value was selected for most stringent site-specific PRG

(1) Screening Levels were as follows:

Indoor air screening levels are CalEPA CHHSLs Indoor Air Screening Levels for Human Health Commercial/Industrial Use (EPA 2005)

Soil screening levels are EPA's Region 9 Preliminary Remediation Goals (PRGs) for industrial soil (EPA 2004c)

Outdoor air screening levels are EPA's Region 9 Preliminary Remediation Goals (PRGs) for industrial soil (EPA 2004c)

(2) Soil Gas site-specific PRGs were calculated using ratios of soil gas concentrations to calculated risks and hazards. See Tables D-3.1 to 3.6.

TABLE D-4.2
