

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON D.C. 20460

OFFICE OF THE ADMINISTRATOR
SCIENCE ADVISORY BOARD

DATE

EPA-SAB-13-XXX

The Honorable Lisa P. Jackson
Administrator
U.S. Environmental Protection Agency
1200 Pennsylvania Avenue, N.W.
Washington, D.C. 20460

Subject: SAB Advice on Advancing the Application of Computational Toxicology Research for Human Health Risk Assessment

Dear Administrator Jackson:

The Science Advisory Board (SAB), as well as the National Academy of Sciences, has encouraged the EPA to improve its risk assessment practices and to modify its single-chemical approach. Tens of thousands of chemicals are currently in commerce and hundreds more introduced every year, yet only a small fraction have been adequately assessed for potential hazard. To meet this challenge, the agency established the Computational Toxicology (CompTox) Research Program to explore ways to exploit modern advances in molecular biology, chemistry, exposure science and computer science to more effectively and efficiently assess chemical hazards and ultimately their risks. The SAB previously has underscored the importance of this research program and has been interested in the successful application of CompTox data to advance the EPA's hazard assessment and, in combination with exposure data, risk assessment.

In addition to permitting more rapid evaluation of individual chemicals, the CompTox research program also has the potential to provide the agency with a means of shifting its traditional focus on single stressors, endpoints, sources, pathways and environmental media to evaluate, more broadly, multiple factors simultaneously. To assist the EPA in this process, the SAB asked its Exposure and Human Health Committee to evaluate how the products from the CompTox research program are being used by EPA, whether the program outputs align with the needs of the EPA's programs and whether limitations or challenges to using CompTox hazard and exposure data in decision-making for risk assessment can be identified and addressed. The SAB committee, along with two members of the EPA Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) Scientific Advisory Panel, received briefings from EPA representatives regarding the use of CompTox research program outputs as one component into EPA risk assessments. In the enclosed report, the SAB provides its analysis and advice regarding the issues that the agency should consider as they move forward with implementation. This letter highlights the SAB's major recommendations.

The SAB commends the EPA for undertaking the immense effort of establishing the CompTox research program. The program is still in the development stage and the agency has not yet begun to incorporate the information derived from it into various applications (e.g., prioritization, screening or

1 risk assessment). However, the program already has contributed to the EPA's efforts to conduct a
2 rapid response evaluation of chemicals. For example, EPA's ability to employ high-throughput
3 screening (HTS) assays to test for endocrine activity in the eight candidate oil dispersants for use
4 during the Gulf of Mexico Deepwater Horizon accident was possible, in part, due to the existence of
5 the CompTox research program. While the agency was able to obtaining such test data in a short
6 timeframe, the crisis highlights the need to develop a structured approach for utilizing the CompTox
7 information in emergency situations. Specifically, in the case of the Deepwater Horizon accident, a
8 very limited subset of assays was used to evaluate the dispersants. Were the data derived from this
9 limited set of assays the most appropriate? Were they sufficient? The need to obtain data quickly to
10 inform decisions in a crisis emphasizes the importance of developing a structured approach
11 beforehand in the form of data use guides (DUGs). These DUGs should be developed after a
12 thorough characterization of programmatic needs –the intended goals of a prioritization effort,
13 screening or a risk assessment – together with the identification of examples of where CompTox
14 information appears to add value.

15 The challenges that the EPA faces regarding the various applications of CompTox data are substantial
16 and are well known to the agency. These include, but are not limited to, detailed characterization of
17 each individual assay, determining the accuracy of the assays against traditional *in vivo* studies,
18 determining how the data generated predict effects on apical endpoints or empirically verifiable
19 outcomes of exposure (e.g., developmental anomalies) employed in validated guideline studies and
20 the ways in which these patterns of data predict the risk of human disease. The latter issue is the most
21 difficult. As the agency elucidates the Adverse Outcome Pathways (AOPs) that would link these
22 patterns to human disease, there are new methodologies using new cell and tissue types that may
23 prove useful to link early gestational exposures or environmental insults to many common disorders.
24 The EPA would be well-served to partner with professional societies and research institutes whose
25 mission is to understand the diseases under investigation to gain further insight.

26 Exposure science also will be critical to prioritize chemicals for screening and further assessment.
27 While the CompTox research program is currently focused on understanding AOPs, a similar effort
28 for incorporating metabolism and other toxicokinetic factors, and understanding exposure (e.g.
29 through the CompTox ExpoCast effort) is needed before these approaches can be fully applied in
30 decision-making. Methods for incorporating biomonitoring data, exposure pathways, chemical source
31 information, and information on human activity patterns also need to be developed and incorporated
32 into risk assessments. A clear explanation of the limitations of the models, the reliability of the assay
33 systems, the certainty associated with an AOP and knowledge of the metabolism of the chemical
34 being assessed are only some of the important considerations that should be addressed when
35 screening untested chemicals or developing the hazard or exposure component of a risk assessment.

36 Demonstrating the predictive value of CompTox data and its utility for the EPA's decisions is needed
37 to overcome barriers to its acceptance within and outside the agency. This will require a combination
38 of research to develop reliable methods and experience in using them to predict hazard and risk,
39 relative to more traditional methods. Through incremental change to the current approaches for
40 assessing risk, first in supplementing and later by replacing existing methodologies, the EPA likely
41 will be able to demonstrate the value of these new technologies, which will lead to greater confidence
42 in the use of CompTox and ExpoCast as predictive tools to understand hazard and risk.

43 Outreach, training and communication also are vital to effective implementation of CompTox outputs
44 and advancing EPA risk assessment. Efforts to reach out to EPA program offices that could benefit
45 from CompTox data and engaging stakeholders to communicate the value and utility of the research

1 program are laudable and should continue. We commend EPA for establishing the Computational
2 Toxicology Communities of Practice which is composed of more than 300 people from over 50
3 public and private sector organizations interested in the application of computational toxicology and
4 exposure science to EPA's risk assessments. We also support the agency's goal of transparency,
5 publishing all the data online so that the public can view and interpret these data. In fact, these data
6 will likely be the source of numerous Ph.D. dissertations in the near future. However, the website
7 (<http://www.epa.gov/ncct/>) is somewhat difficult to navigate and it would be useful for the agency to
8 redouble their efforts to ensure that the public can access the data with relative ease.

9 In summary,

- 10 • The SAB applauds the work of the CompTox research program, and recommends the
11 continued development of CompTox outputs to lead to a better understanding and
12 expansion of the potential utility of this technology.
- 13 • EPA should explore partnerships with clinical and research societies whose members
14 represent the experts in mechanisms of disease to help the agency develop AOPs.
- 15 • EPA should develop data use guidelines for information generated by CompTox,
16 including ExpoCast, for the various purposes to which it is intended.
- 17 • EPA should increase its efforts to understand chemical exposure, including determining
18 how and where the chemicals are used and activity patterns of people that will result in
19 exposure and not just the chemicals' movement through the environment based on
20 fundamental chemical properties.
- 21 • We encourage the agency to continue to engage stakeholders and provide easy access to
22 data on the CompTox website.

23 As the EPA gains more experience and expertise in the use of CompTox outputs in risk assessment,
24 along with the development of ExpoCast, we look forward to future opportunities for providing
25 advice to EPA on this important effort.

26
27
28
29 Sincerely,
30

This report has been written as part of the activities of the EPA Science Advisory Board, a public advisory group providing extramural scientific information and advice to the Administrator and other officials of the Environmental Protection Agency. The Board is structured to provide balanced, expert assessment of scientific matters related to the problems facing the agency. This report has not been reviewed for approval by the agency and, hence, the contents of this report do not necessarily represent the views and policies of the Environmental Protection Agency, nor of other agencies in the Executive Branch of the Federal government, nor does mention of trade names or commercial products constitute a recommendation for use. Reports of the EPA Science Advisory Board are posted on the EPA website at <http://www.epa.gov/sab>.

GLOSSARY

AOP or Adverse Outcome Pathways provide a scientific approach for linking mechanistic information to responses considered relevant to risk assessment and management. AOPs refers to pathways that would: (1) proceed from an initiating molecular event in which a chemical interacts with a biological target (e.g., DNA binding, protein oxidation, or receptor/ligand interaction); (2) continue on through a sequential series of biological activities (e.g. gene activation, or altered cellular chemistry or tissue development); and (3) ultimately culminate in an adverse outcome of relevance to human or ecological risk assessors (e.g., mortality, disrupted reproduction, cancer, or extinction).

Apical Effects or Endpoints - empirically verifiable outcomes of exposure, such as developmental anomalies, breeding behaviors, impaired reproduction, physical changes and alterations in the size and histopathology of organs, or death.

CompTox or the EPA's Computational Toxicology research is part of EPA's broader Chemical Safety research efforts. CompTox is researching new, more efficient, ways to assess chemical safety for potential risk to human health and the environment that can replace traditional chemical toxicity testing that is expensive, time consuming and uses a significant number of animals.

CSS or Chemical Safety for Sustainability is one of six transdisciplinary research programs in EPA's Office of Research and Development which focuses on the use of systems-approaches to advance the understanding of the links between exposures to chemicals and toxicity pathways that lead to the development of disease.

ExpoCast- A collaborative effort across the exposure and risk assessment community to provide the exposure science required for interpretation of high-throughput *in vitro* toxicity data. The overall goal of this program is to develop novel approaches and tools for evaluating and classifying chemicals, based on potential for biologically-relevant human exposure, to inform prioritization and toxicity testing.

Omics - refers to a broad field of study in biology, ending in the suffix "-omics" such as genomics, proteomics, transcriptomics.

Tox21- A collaborative effort of the EPA, National Institutes of Environmental Health Sciences/National Toxicology Program, National Institutes of Health and the Food and Drug Administration that is pooling federal resources and expertise in the use of robotics technology to screen thousands of chemicals for potential toxicity, use screening data to predict the potential toxicity of chemicals and develop a cost-effective approach for prioritizing the thousands of chemicals that need toxicity testing.

ToxCast- A multi-year effort launched by EPA in 2007 to develop a cost-effective approach for prioritizing the thousands of chemicals that need toxicity testing. ToxCast uses advanced science

1 tools to help understand how human body processes are impacted by exposure to chemicals and to
2 determine which exposures are most likely to lead to adverse health effects.

3

4 **ToxPi** or Toxicological Priority Index is a tool which profiles the interactions of chemicals with
5 biological processes in ways the public and decision makers can easily understand. ToxPi is a flexible
6 prioritization support software tool that incorporates ToxCast bioactivity profiles, inferred toxicity
7 pathways, dose estimates and chemical structural descriptors to provide a visual representation of the
8 relative contribution of each data domain to an overall priority score.

9

10 **ToxRef** - a comprehensive relational database of mammalian toxicity studies developed by EPA's
11 Office of Research and Development in collaboration with EPA's Office of Pesticide Programs
12 (OPP).

1. INTRODUCTION

1
2
3 In 2007, the National Research Council (NRC) Committee on Toxicity Testing and Environmental
4 Assessment published a study, *Toxicity Testing in the 21st Century: A Vision and a Strategy* (NRC
5 2007). In this report, the NRC Committee recommended developing a program that would
6 incorporate modern tools to provide information about chemical toxicity for use in risk assessments.
7 The overall goal of such a program would be to enhance the efficiency and effectiveness of chemical
8 safety determinations. Guided by the NRC report, the EPA in that same year launched ToxCast™, an
9 initiative to employ rapid automated chemical toxicity tests as part of the Computational Toxicology
10 (CompTox) Research Program. The CompTox program conducts innovative research that integrates
11 advances in molecular biology, chemistry and innovative computer science to more effectively and
12 efficiently rank chemicals based on risks. The aim of the CompTox program is to take advantage of
13 existing technologies to develop ways to predict the toxicity of the thousands of chemicals for which
14 toxicity testing is lacking or absent.

15 In a recent report on the FY2012 EPA research budget, the EPA Science Advisory Board (SAB)
16 noted its concern that, “...*there is no proactive budget initiative to develop ways of employing the*
17 *results of the [Chemical Safety for Sustainability] CSS program, including high throughput data, into*
18 *hazard or risk assessment*” (U.S. EPA SAB 2012). The CSS program, one of six transdisciplinary
19 research programs within the EPA’s Office of Research and Development, is responsible for
20 coordinating the activities of the CompTox research program. In addition to allowing more rapid
21 evaluation of a large number of individual chemicals, CompTox has the potential to provide the
22 agency with a means of modifying its traditional focus on single stressors, endpoints, sources,
23 pathways, and environmental media to a broader focus on evaluation of these factors in combination
24 to evaluate the potential effects of the co-occurrence of multiple chemicals. For these reasons, the
25 SAB has requested that its Exposure and Human Health Committee (EHHC) develop advice to assist
26 in advancing the application of CompTox research for human health risk assessment to meet EPA’s
27 programmatic needs. In developing its advice to EPA, the EHHC engaged in discussions with ORD
28 and EPA program offices, which currently use or plan to use the CompTox research outputs, in order
29 to address the following questions:

- 1 1) Are the outputs of CompTox currently being used by EPA? How well do the outputs
2 align with EPA's programmatic needs?
- 3 2) What issues are there in using CompTox in decision making for risk assessment and
4 risk characterization as opposed to chemical screening, prioritization and green
5 chemistry?
- 6 3) What are the barriers and limitations that prevent the EPA from using CompTox
7 outputs and how might they be overcome? and
- 8 4) How should the use of the CompTox program be effectively communicated to
9 stakeholders? How can the communication be enhanced?

10 The members of the EHC were joined for this review by two members of the EPA Federal
11 Insecticide, Fungicide, and Rodenticide Act Scientific Advisory Panel (FIFRA SAP) who had
12 reviewed elements of the ToxCast program in 2011¹. The committee was briefed by representatives
13 from ORD and program offices ((e.g., pesticides, water or toxics)) regarding the overall scope,
14 structure and organization of the program, and the use of ToxCast information within the programs
15 represented. The EHC met with representatives of the EPA in a face-to-face meeting on May 30-31,
16 2012, and discussed the study questions. A draft committee report was discussed at a teleconference
17 on September 24, 2012, and the chartered SAB considered the draft report on (DATE). The following
18 report outlines the SAB's impressions of the work undertaken by the CompTox research program and
19 recommendations on how to enhance the utility of the program outputs.

20

¹ Report available at the following URL: <http://www.epa.gov/scipoly/sap/meetings/2011/may/052411minutes.pdf>

1 **2. SAB STUDY FINDINGS AND RECOMMENDATIONS**

2 **2.1. Applications of CompTox to EPA Programs**

3 *Study Question 1. Are the outputs of CompTox currently being used by EPA? How well do the*
4 *outputs align with EPA’s programmatic needs?*

5 The ToxCast program, an effort coordinated by the CompTox program, currently consists of nearly
6 700 individual assays provided by nine companies. A foundational element of ToxCast is a chemical
7 library in which a large number of chemicals are simultaneously tested to create toxicity profiles in
8 these assays. In Phase I, chemicals for which there is a substantial amount of toxicity data have been
9 assayed, including 309 pesticide active ingredients and commercial chemicals. These chemicals will
10 be assayed to provide a “proof of concept”; i.e., the results will be used to develop toxicity profiles
11 and evaluate the ability of the assays to predict toxicity. In Phase II, about 2,000 chemicals from a
12 broad range of sources including industrial and consumer products, food additives, “green” products
13 (those that reduce or eliminate the use or generation of hazardous substances), nanomaterials and
14 drugs that never made it to the marketplace are being screened. This information will be used to
15 identify pathways of toxicity – patterns of responses observed in the CompTox assays that are
16 plausibly and causally related to observations of apical effects or empirically verifiable outcomes of
17 exposure (e.g., developmental anomalies) in the *in vivo* assays.

18 At present, the primary use of CompTox outputs has been to determine the reliability of the data for
19 use in various types of decision-making by EPA programs. One example of where information
20 derived from the CompTox research program has been used to inform agency decisions has been
21 provided (see below). Despite the limited use of Comptox outputs to date, the SAB finds that the
22 program is valuable and has made impressive progress in the five years since the inception of
23 ToxCast.

24 The reliability of ToxCast data is currently being explored in two ways. First, data from ToxCast is
25 being compared to data from ToxRef, a database of toxicity studies conducted with guideline, *in vivo*
26 test systems. By comparing the effects of individual chemicals in both ToxCast and ToxRef, the EPA
27 hopes to identify parallels that will provide confidence that decisions based on ToxCast data will be
28 predictive of results for endpoints assessed using *in vivo* guideline studies. A second approach is to
29 develop pathways of toxicity in humans that would lead to the clinical manifestation of disease.

1 These adverse outcome pathways” (AOPs) represent a very important link from *in vitro* high-
2 throughput assays to human disease, and this effort is just beginning. EPA should explore AOPs not
3 only based upon how a chemical can perturb biological systems but also from the perspective of how
4 aging and disease processes have underlying AOPs which may be sensitive to chemical effect. By
5 evaluating upstream events, EPA has the ability to use CompTox data for evaluating how chemical
6 and disease AOPs may intersect leading to a more complete understanding of chemical action (NAS
7 2009).

8 EPA researchers in the CompTox program are also exploring the possibility that ToxCast data can be
9 combined with large databases of experimental data at the level of the genome, epigenome, proteome
10 and metabolome to provide higher resolution data within the context of AOPs. In principle, weight-
11 of-evidence approaches would be developed to guide the integration of this information into current
12 data and practices for hazard identification and perhaps risk assessment. If successful, this effort is
13 expected to shape the future of toxicity testing at EPA in accordance with the recommendations of
14 previous NAS reports, paying large dividends for the agency, researchers and the American public
15 that are well worth the investments currently being made.

16 The outputs of the ToxCast program are being developed to align with the needs of EPA programs
17 both in the long- and short-term. The EPA faces significant challenges to understanding how
18 information derived from ToxCast can be employed to inform the various decisions required of the
19 agency. These efforts will require constant communication between the different programs within the
20 agency in order to ensure that the outputs meet the needs of the specific programs. At the SAB
21 committee meeting in May 2012, EPA representatives from ORD and program office (e.g.,
22 pesticides, water or toxics) devoted considerable time to describing how this coordination is
23 occurring. EPA’s expectation is that the current research questions and research approach, as outlined
24 above, will produce a program that will have broad applicability within the agency.

25 EPA used the high-throughput screening (HTS) assays that form the basis of the CompTox program
26 in a trial approach to supplement the EPA’s response to the Deepwater Horizon accident by
27 calculating toxicity data (endocrine activity screens) on the eight oil dispersants employed by BP in
28 the Gulf of Mexico. Having a formal CompTox program in place within EPA at the time of the
29 Deepwater Horizon accident made it easier to employ these assays. This illustrates a number of
30 important ancillary benefits of this program. One benefit is to have an infrastructure that would allow

1 rapid data generation so that the agency can make better-informed decisions in a disaster situation.
2 Pairing this data with ExpoCast information (i.e., use novel approaches and tools for evaluating and
3 classifying chemicals, based on potential for biologically-relevant human exposure) to evaluate
4 potential exposure in response to emergencies could provide a more holistic assessment of the
5 associated risk. Another benefit is that development of the CompTox program has required a great
6 deal of interaction between various EPA offices. This interaction will foster greater communication
7 about data needs and data interpretation. This interaction also helps to ensure that the intramural
8 research program aligns with the routine and sometimes unanticipated needs of the agency as well as
9 to help risk assessors identify early the data gaps that may be filled by the kind of information
10 produced by CompTox. Additionally, the CompTox program provides an alternative means of
11 evaluating multiple factors that might influence the risk posed by chemicals through the use of
12 automated assays. The CompTox program provides the agency with a means of shifting its traditional
13 focus on single stressors, endpoints, sources, pathways, and environmental media to a broader focus
14 on the evaluation of these factors in combination or the potential co-occurrence among these factors.

15 However, the Deepwater Horizon accident also illustrates that in emergency situations CompTox data
16 may be generated and used very rapidly without the opportunity to fully screen a chemical's toxic
17 properties. Strategic planning is needed in advance of such events so the endpoints and assays
18 available are predictive of adverse effects and relevant to the scenario at hand and to ensure some
19 consistency across programs and applications. The limitations of such screening exercises must be
20 described so as not to imply that the data predict risk (by themselves they do not constitute a risk
21 assessment) or that the data present a complete toxicological description of effects the chemical can
22 cause. With such caveats in mind and transparently stated, CompTox can be seen as an aid to risk
23 management. The Data Use Guide (DUG) proposed later in this document will assist in the design
24 and interpretation of CompTox screens for different scenarios.

25 **2.2. Evaluating CompTox Outputs for Decision-making**

26 *Study Question 2. What issues are there in using CompTox in decision making for risk assessment*
27 *and risk characterization as opposed to chemical screening, prioritization and green chemistry?*

28 **2.2.1. Specificity and Sensitivity of CompTox Data**

29

1 A central question at this time is whether the *in vitro* high-throughput assays will produce data that
2 will be suitable for decision-making such that, eventually, these data could replace *in vivo* testing for
3 regulatory decisions. The answer to this question will undoubtedly depend on the level of decisions to
4 be made. Thus, an important – if not essential – goal will be to sufficiently demonstrate and obtain
5 widespread support for the data generated from ToxCast by risk assessors. This will also need to be
6 consistent with statutory requirements for the evidence the EPA uses to take regulatory action. Thus,
7 a principal goal of the research domain of the program is to characterize the data generated from
8 ToxCast assays in terms of the specificity, sensitivity and reliability of the individual assays, as well
9 as their ability to predict toxicity either alone or in combination with other findings. The agency
10 appears to be making good progress toward these goals.

11 The agency has adopted two general strategies for testing the value of ToxCast data for agency use.
12 The first strategy is to identify the patterns of responses for each chemical in the battery of ToxCast
13 assays and correlate these with the biological activities observed in guideline, *in vivo* studies
14 associated with the same chemical. This strategy is made possible by considerable amount of *in vivo*
15 data associated with the Phase I chemicals. Of course, the assays included in ToxCast were pre-
16 existing HTS assays developed for the pharmaceutical industry; they were not designed for ToxCast
17 to correlate with endpoints in guideline *in vivo* studies. Therefore, it would be useful if the agency
18 considered developing the theoretical framework that would support the effectiveness of this strategy.
19 Essentially, this amounts to developing “AOPs” for the *in vivo* guideline studies.

20 The second strategy is to develop AOPs for human disease that may be reflected in the ToxCast data.
21 This is an important and valuable strategy and highlights an important weakness in these two
22 strategies that can be addressed in the commission of building these AOPs. Specifically, the ToxCast
23 assays were not designed by the agency to inform *in vivo* endpoints, and the guideline *in vivo*
24 endpoints were not designed overtly to inform human disease. Thus, to build a credible system, the
25 EPA needs to focus on making the case that there is a relationship between what is observed in the
26 ToxCast assays, what is observed in the guideline studies, and what is observed (or expected) in the
27 human population.

28 The data derived from CompTox assays should lend themselves readily to hazard identification and
29 especially green chemistry. These data may provide insight for the development of chemical products
30 that have a greater likelihood of being free from toxic properties. Moreover, CompTox data may be

1 combined with information from structure-activity relationship (SAR) evaluation and any *in vivo* data
2 that might be available, to facilitate hazard identification and help guide a weight-of-evidence
3 analysis of hazard. However, there are several cautions that need to be considered when applying the
4 data for hazard evaluation. First, the strengths and limitations of each assay must be recognized,
5 including the potential for false negative and false positive results. Given that pathways of toxicity
6 are poorly understood, current *in vitro* assays cannot be seen as comprehensive in their scope. For
7 example, according to Judson et al. (2010), CompTox models developed to screen for chronic,
8 developmental and reproductive toxicity endpoints display high specificity (few false positives) but
9 only moderate sensitivity (multiple false negatives). [Sensitivity relates to the assay's ability to
10 identify positive results. Specificity relates to the ability of the assay to identify negative results.]
11 Therefore, the rate of false negatives is expected to be high at this stage of the program. While some
12 information is better than none, there is concern that too much confidence will be placed upon the
13 lack of activity in the available assays. If there is a high degree of reliance on data from these assays,
14 it may inappropriately give the appearance that a chemical with no activity is safer than other,
15 alternative chemicals that in fact have more information available.

16 **2.2.2. Incorporating Exposure Information**

17 EPA also should consider the potential for exposure to the chemical when determining the degree of
18 testing required such that even if initial screens of a chemical find little reason for concern, *in vivo*
19 confirmation may still be desirable if the chemical's exposure potential is high. Conversely, low
20 exposures may diminish the need for extensive toxicity testing than might be needed for agents whose
21 exposure is greater. These considerations underscore the need for good exposure/biomonitoring
22 information which at this point appears to be a limitation of CompTox modeling. There is also
23 uncertainty about the significance of a positive result in any particular assay within ToxCast. A major
24 effort is underway to link patterns of responses within the battery of ToxCast assays to AOPs. At
25 present, the ability to link patterns of responses and AOPs is limited since many of the screening
26 assays are still under development and going through validation exercises on an individual level.
27 Additionally, there is also a need to better understand the relationships between AOPs and apical
28 endpoints. The concept is that by evaluating the behavior of known toxicants in the ToxCast battery,
29 patterns of toxicity linking this HTS behavior to adverse outcomes and thereby enhancing
30 predictability will become apparent and will serve as validation of the predictive capability of the
31 assay.

1 Ultimately, the usability of a given result will be dependent upon additional data that is available for
2 the chemical in question and about the tests and pathways affected by that chemical. The advantage
3 of CompTox is that thousands of tests can be conducted – these need to be inclusive of as many
4 potential health effects as possible. EPA should make clear the limitations of the information that can
5 be obtained from the breadth of assays. For example, the testing may be accurate for cancer,
6 developmental and reproductive endpoints, endocrine and metabolic endpoints, liver and kidney
7 effects, but not, for example, eye health or neurological health. Positive results on subsets of tests or
8 tests along certain pathways could suggest further testing and/or *in vivo* studies. Of particular
9 importance for public health is the accuracy of a negative result in an assay system, which in a
10 screening step could result in a decision to not proceed with further testing. In other words, for
11 chemical screening and prioritization, the testing should be sensitive (i.e., detect an effect when there
12 is one) and specific (i.e., does not detect an effect when there is not one).

13 Regarding more advanced uses of CompTox outputs beyond hazard identification (e.g., use in dose-
14 response assessment and risk assessment) the following additional concerns should be considered:

- 15 • Have the most sensitive endpoints been identified in the CompTox assays;
- 16 • How well do these CompTox endpoints relate to apical endpoints such as carcinogenesis,
17 endocrine disruption, organ toxicity, neurotoxicity and immunotoxicity;
- 18 • How would the uncertainty factors used when starting with *in vivo* data (e.g., interspecies,
19 intraspecies, acute to subchronic to chronic study duration, database quality and
20 completeness) be applied and/or modified for *in vitro* screening data;
- 21 • How would the *in vitro* dose-response relate to *in vivo* behaviour when considering route
22 of entry, metabolic activation and detoxification systems that may not be present *in vitro*;
- 23 • How would the *in vitro* dose-response relate to *in vivo* behaviour when considering other
24 toxicokinetic factors governing the external dose associated with a particular concentration
25 at the target cell or receptor that may not be taken into account *in vitro*? These factors
26 include metabolic activation and detoxification, as well as, absorption through relevant
27 route(s) of entry, distribution, and excretion; and

- 1 • Related to the third bullet above, how well do the *in vitro* test methods capture intra-
2 human variability in terms of susceptible sub-populations and life stages including genetic
3 polymorphisms and disease states?

4 To move towards the development of risk assessments that more accurately reflect environmental
5 conditions, EPA's CompTox research program also needs to develop strategies for studying
6 environmental chemical mixtures - not just the effects of one chemical at a time. The importance of
7 using CompTox to characterize the hazard, and ultimately the risk, of environmental chemical
8 mixtures cannot be overstated. Moving in this direction requires establishing a scientifically
9 defensible foundation -for example, by defining appropriate AOPs, developing testing methods that
10 address a wide array of AOPs, and evaluating the accuracy, sensitivity and specificity of the tests.
11 While assessment of mixtures may ultimately be a long range goal, the path to studying and
12 estimating risk from mixtures should be outlined. Examples of critical questions include the
13 following: (1) How will relevant mixtures be identified? (2) Can methods be developed to predict the
14 hazard and/or risk of mixtures of chemicals from CompTox data on individual chemicals which affect
15 the same AOP(s); (3) How will risk be quantified for different types of endpoints based on effects on
16 relevant AOPs? and (4) How much risk is allowable for a given AOP?

17 As already noted, exposure is a key component of risk assessment and one that needs greater focus
18 within the CompTox program. A general approach, based solely on chemical properties, that
19 evaluates transport from large sources and partitioning based on fugacity concepts to predict the
20 distribution of chemicals from their sources to a population will NOT provide a full exposure
21 evaluation and will lead to misclassification of exposure. Such an approach is analogous to saying
22 that nothing needs to be known about metabolism of chemicals when determining toxicity and that
23 the only information needed is the overall chemical structure and what functional groups are present
24 to compare with known compounds. Exposure may occur when people come into contact with
25 chemical agents and often results from being close to the source where the agent is released into the
26 environment. For example, an agent produced in relatively small quantities but used in personal
27 products can result in a higher exposure than a high production volume chemical emitted from point
28 sources located away from populations. The higher exposure potential of a low production chemical
29 would not be predicted based on an exposure model that does not include information on its use and
30 potential contact with people. Thus, if these two agents were equally hazardous, the low production

1 compound would present greater risk, but it is unclear if the current assays used in the CompTox
2 program would account for this situation. This issue is relevant to all of the EPA applications listed,
3 i.e., chemical screening, prioritization, risk assessment and green chemistry.

4 **2.2.3. Data Use Guidelines**

5 A key issue affecting use of CompTox data is the need for a guide to explain the appropriate use of
6 data in various applications. Guidance for data needs (and sufficiency or appropriateness of data)
7 must come from a good characterization of EPA programmatic needs – identification of both the
8 intended goals of a risk assessment or a prioritization effort – and examples in which CompTox
9 information appears to add real value. While the data are meant to be used within a weight-of-
10 evidence context that requires integration across all of the available data (e.g., *in vivo* toxicology data,
11 SAR, read-across approaches, other supporting *in vitro* data), it may be beneficial to establish general
12 principles for the use and interpretation of the output for any one endpoint or health effect in a Data
13 Use Guidance (DUG) document. Key aspects to address in such a guidance document include:

- 14 1. Name of the assay;
- 15 2. Description of assay design;
- 16 3. Name of company that developed the assay;
- 17 4. Information on any proprietary constraints of the assay;
- 18 5. Positive control and other agents used to characterize the assay;
- 19 6. Dynamic range of the assay;
- 20 7. Where the endpoint fits within one or more AOPs;
- 21 8. Related CompTox endpoints (i.e., endpoints likely to be within the same AOP or that are
22 indicative of similar biological activity but in an independent test system);
- 23 9. Interpretative value of the endpoint if altered in isolation;
- 24 10. Interpretative value if altered in conjunction with other “aggregated” endpoints;
- 25 11. Rate of false positive and negative results if it is to be used for predictive purposes (e.g., to
26 forecast *in vivo* endocrine activity);
- 27 12. Shape of the dose-response curve (e.g., monotonic, non-monotonic, threshold, linear);

- 1 13. Potential for the endpoint to be used as a biomarker in toxicity testing or in epidemiology
- 2 studies;
- 3 14. Whether the endpoint is also affected by disease processes that might potentially lead to a
- 4 chemical/disease interaction;
- 5 15. Limitations and uncertainties of the endpoint; and
- 6 16. Cross reference with other assays that assess the same endpoint(s) and comparison of
- 7 reliability of the assay in comparison.

8

9 It may also be helpful to develop a simple flow chart describing a continuum extending from the least
10 amount of evidence for a meaningful effect (e.g., perturbation only at high dose) to the greatest
11 amount of evidence for meaningful effect (e.g., upstream and downstream endpoints affected in a
12 defined AOP with effects occurring on upstream endpoints at low dose and anchored by similar
13 effects from a known toxicant). The DUG also could provide guidance concerning the different uses
14 of the data depending upon where on the continuum the evidence for a meaningful effect lies for a
15 particular chemical. The “ToxPi” pie chart of endocrine-related effects for a chemical appears to be a
16 useful way to illustrate the types of biological activities of a chemical, but not the meaning and
17 importance of individual slices relative to other slices. The DUG could also include a section on
18 aggregated endpoints that describes the implications of a “slice” of the pie for a particular biological
19 effect and how one determines potency for a slice.

20 The concept of a DUG is not new. For example, the Centers for Disease Control/ National Health and
21 Nutrition Examination Survey (CDC/NHANES²) biomonitoring data release provides important
22 information for each exposure type including the normative range in the population, any relevant
23 workplace or environmental standards (e.g., Occupational Health and Safety Administration (OSHA)
24 Biological Exposure Indices), and limitations of the biomarker itself (e.g., specificity, sensitivity).
25 This information is meant to aid in the interpretation of the data by various stakeholders and avoid the
26 over-interpretation of the data. As previously mentioned, the Deepwater Horizon accident revealed a
27 critical programmatic need – the need for rapid toxicological information in response to emergencies

² Information can be accessed at the following URL: <http://www.cdc.gov/nchs/nhanes.htm>

1 or other sudden demands for information and recommendations. There is also a need for developing
2 guidance, procedures and resources for the use of Comptox outputs in such events.

3 **2.2.4. Relating CompTox Outputs to *in vivo* Assay Results**

4 Finally, for CompTox data to be of sufficient quality for use in risk assessment, it must correspond to
5 validated *in vivo* endpoints or well-defined AOPs. Importantly, the batteries of CompTox assays were
6 not specifically designed to inform these endpoints, in contrast to the *in vivo* assays which in some
7 cases were developed decades ago. Further, the validated *in vivo* guideline assays used in assessing
8 toxicity of chemicals were not designed to predict the full range of endpoints that are currently
9 considered to be of public health importance. Ideally, the results of CompTox assays also should be
10 predictive of additional *in vivo* endpoints of more recent interest – for example, diseases in adulthood
11 resulting from developmental exposures. New methodologies, utilizing new cell and tissue types for
12 DNase1 Hypersensitive Site correlation analysis, have been reported in the scientific literature (e.g.,
13 see Maurano et al. 2012). This research has shown that many common disorders are linked with early
14 gestational exposures or environmental insults. Incorporation of this methodology into ToxCast and
15 CompTox will enhance the ability to identify AOPs relevant to a variety of health outcomes.
16 Developing a CompTox research focus on aging and disease processes common in the U.S.
17 population will allow the exploration of AOPs that are not concerned with how a chemical is
18 perturbing “normal” and healthy systems but how chemicals may act in disease pathways to produce
19 health risks in the population. Just as there is an “omics” explosion in describing chemical effects,
20 there is also an explosion in our understanding disease mechanisms/biomarkers and this information
21 should be integrated to give CompTox maximum relevance to human risk.

22 The data generated by Phase I of the CompTox program should build confidence about the
23 relationship between patterns of responses in the battery of tests and the effects of the chemicals
24 being assessed using *in vivo* guideline studies. This empirical analysis, however, will be difficult in
25 part because of: (1) the inherent uncertainties about how the *in vitro* dose response relates to *in vivo*
26 when considering route of entry, metabolic activation and detoxification systems that may not be
27 present *in vitro*; (2) the inherent uncertainties about how the *in vitro* dose response relates to *in vivo*
28 when considering other toxicokinetic factors that govern the external dose associated with a particular
29 concentration at the target cell or receptor; (3) the possibility that a chemical may have more than one
30 mode of action; and (4) the possibility that while two “estrogenic” chemicals may overlap in the

1 patterns of responses observed in the battery of tests, they will likely have large regions of non-
2 overlap. In the absence of prior knowledge of these characteristics, it will be difficult to find the
3 common pattern that predicts the responses observed in current guideline *in vivo* studies. Hopefully,
4 the difficulties in achieving this goal are not insurmountable and over time, through experience with
5 the rapidly increasing database of information that is being generated, the agency will achieve its
6 objective of developing this knowledge.

7 Just as important, and probably even more challenging, will be to understand the relationship between
8 CompTox outputs and the etiology of human disease based on epidemiological data. The CompTox
9 program should work with epidemiologists within the EPA and extramurally to design epidemiologic
10 studies that incorporate new and improved biomarkers of exposure, subclinical effects and disease.
11 The CompTox program is well on its way to addressing these difficult issues.

12 **2.3. Building Scientific Acceptance of CompTox**

13 *Study Question 3. What are the barriers and limitations that prevent EPA from using CompTox*
14 *outputs and how might they be overcome?*

15 There are a number of challenges facing the CompTox program with respect to preparing outputs for
16 use in agency decisions and by the broader scientific community. These challenges are specific to the
17 potential types of applications for these data, including informing decisions when other information is
18 not available, prioritizing chemicals for further toxicity analysis and as the basis for risk assessment.
19 In all cases, a common concern is whether the data generated from high-throughput *in vitro* assays
20 can be applied reliably, i.e., that the data will have been shown to be sufficiently predictive of toxicity
21 *in vivo* and ultimately in humans, relative to traditional approaches such that agency decisions can be
22 scientifically defensible within an acceptable level of uncertainty.

23 It is worth repeating several points that likely serve as barriers to the use of CompTox data:

- 24 (1) If an *in vivo* endpoint is not well anchored in an AOP or read-across approach, then
25 perturbation of that endpoint may be difficult to detect in CompTox assays and thus difficult
26 to apply in screening or risk assessment;
- 27 (2) There must be an understanding of the impact of the route of entry, metabolic activation and
28 detoxification systems and other toxicokinetic factors that may not be present *in vitro*;

1 (3) Dose-response assessment must take into account *in vitro* to *in vivo* extrapolation including
2 metabolism and other toxicokinetic factors, application of uncertainty factors and special
3 consideration of vulnerable sub-groups;

4 (4) There is a likelihood for false negative results at this stage of testing which requires caution
5 when considering a chemical for increased usage based upon CompTox results; and

6 (5) Exposure information is often limited but is a key part of any screening and prioritization
7 program, as well as necessary for risk assessment.

8 The CompTox program is in the development stage, as noted in response to Study Question 1, and so
9 its use is still very limited. The program has not had sufficient time to demonstrate that it can deliver
10 on its promise. Questions about the reliability of individual assays, the availability of assays
11 predictive of the full range of relevant endpoints, the power of “pattern recognition” as a predictor of
12 toxicity, the value of the current design of the system to generate the kind of information needed to be
13 predictive, all are legitimate questions that require time and experience to answer. Considering the
14 importance of these goals and the complexity of the issues involved, there will be unavoidable “blind
15 alleys”. However, the number of these “blind alleys” may be minimized by being more proactive
16 about building AOPs and pathways of toxicity. In this regard, there are currently no internationally
17 accepted methods in the scientific literature for performing a weight-of-evidence analysis for such
18 pathways. While this task is not the purview of the CompTox program *per se*, the ability of the EPA
19 to employ peer-reviewed science in the Tox21 initiative, which combines the efforts of several
20 federal agencies (i.e., EPA, NIEHS and FDA) to screen thousands of chemicals for potential toxicity,
21 would be enhanced by developing an accepted method of analysis for determining the ability of
22 CompTox assays to predict human disease. In the absence of such an accepted method, the agency
23 will be limited in associating CompTox data to data generated from guideline assays and this would
24 be a severe limitation.

25 One of the ways to improve acceptance of CompTox and overcome some of the barriers to its use is
26 to demonstrate that it provides equivalent (or more accurate) answers relative to the currently
27 accepted methods for characterizing hazard and estimating risk. Moreover, if it does so with fewer
28 resources (e.g., cost and time), thereby allowing for the characterization of the large number of agents
29 that the EPA must make decisions about, then it will quickly become the methodology of choice.

1 There also is a need to commit similar resources to develop ExpoCast in parallel to CompTox to more
2 fully support the needs of EPA programs. This will require not only acceptance by scientists at EPA's
3 National Exposure Research Laboratory (NERL) but also a recognition by others within the agency
4 that exposure is a key component of risk assessment, risk characterization and risk management and
5 that the volume of an emission is not equivalent to exposure and the dose humans receive.

6 According to the EPA's 2009 strategy document on evaluating chemical toxicity (U.S. EPA 2009),
7 the agency appears to be following the recommendation of the NRC 2007 committee, "...*in vitro*
8 tests would be developed not to predict the results of current [animal] apical toxicity tests but rather
9 as [human] cell-based assays that are informative about mechanistic responses of human tissues to
10 toxic chemicals. The NRC committee is aware of the implementation challenges that the new
11 toxicity-testing paradigm would face." With this in mind, the EPA is currently conducting research to
12 identify AOPs that can serve as predictors of toxicity; the need to relate these AOPs to currently
13 understood toxicity endpoints is critical. Once appropriate AOPs are established, the EPA will be
14 positioned to transition to the methodologies recommended by the NRC. However, as the agency
15 pursues this path, EPA will need to address several questions:

- 16 • How well do the *in vitro* and *in silico* tests translate to human systems?;
- 17 • How predictive of human pathways are the identified AOPs? Data on this is important to
18 share and make public;
- 19 • How do the testing methods account for differences between *in vitro/in vivo* animal testing
20 and human toxicokinetics, particularly metabolism but also absorption, distribution, and
21 excretion? (for instance, how are chemicals that are cleared through multiple pathways (renal,
22 GI, etc) treated in the analysis; how do these testing methods account for chemicals that are
23 actively reabsorbed by renal organic anion transporters or those that are strongly bound to
24 plasma proteins, lipids, etc. And how would the testing methods determine the toxicity of
25 chemicals which are initially metabolized in one organ and further metabolized to the ultimate
26 toxic metabolite in another organ?;
- 27 • Given that there are multiple methods to estimate pharmacokinetic behavior (as described in
28 Rotroff et al. 2010) and since the results may differ based on which methods are employed,
29 how will decisions be made regarding which ones to use, their accuracy and certainty?;

- 1 • Are the proposed tests useful for chemicals that are stored in humans (e.g., adipose tissue
- 2 depot or other sites)?
- 3 • How are human exposure characterization and biomonitoring data used in the prioritization
- 4 and testing of chemicals (although the tests are designed to identify chemical hazards, if
- 5 exposure is low or non-existent then how should the chemical be prioritized)?
- 6 • Where will human exposure data, which should be a high priority since it is such an important
- 7 component of risk assessment, come from, how they will it be used (upper bounds, central
- 8 tendency, etc.); and,
- 9 • How are existing data from the scientific literature incorporated into these AOPs and how will
- 10 the AOPs remain current?

11

12 The scientific acceptance of CompTox approaches in a weight of evidence for decision-making will
13 depend on the accuracy, sensitivity and specificity of the computational toxicity testing for predicting
14 actual and potential human health effects. To assist in gaining acceptance, a transparent strategy
15 should be developed for quantifying the endpoints upon which risk assessments will be based. The
16 agency also should indicate what issues should be considered for EPA applications such as chemical
17 screening, prioritization, risk assessment and green chemistry. While relevance to humans is always
18 important, these applications may be ranked in order from highest to lowest in terms of the scrutiny
19 with regard to human relevance as follows: risk assessment, prioritization, screening chemicals and
20 green chemistry.

21 Finally, the interactions between ORD and the various EPA programs (e.g., pesticides, water or
22 toxics) that will use CompTox data are commendable and should continue in order to understand
23 what would make such data most useful. Perhaps, in addition to providing opportunities for program
24 office scientists to spend time in the ORD laboratories to become familiar with the CompTox
25 program, extensive remote learning and training modules could be developed to reduce the cost and
26 logistic challenges. This may also serve to engage more key EPA scientists outside of the ORD
27 laboratories located in Research Triangle Park, North Carolina area.

28 **2.4. Communicating CompTox Approaches and Outputs**

29 *Study Question 4. How should the use of the CompTox program be effectively communicated to*
30 *stakeholders? How can the communication be enhanced?*

1 The EPA appears to be doing a very thorough job of communicating to stakeholders about the
2 CompTox program. The agency has created multiple web-based learning tools and models such as
3 webinars and dashboards for the interested public to learn more about the program and to access the
4 data it is generating. The EPA has actively sought input from stakeholders as it developed the
5 CompTox program and also has disseminated information to the scientific community through
6 publications and presentations at scientific conferences. The EPA established the Computational
7 Toxicology Communities of Practice, composed of more than 300 people from over 50 public and
8 private sector organizations that are interested in the application of computational toxicology and
9 exposure science to risk assessments. The SAB commends this effort; it is a powerful tool for keeping
10 up with technical issues that the EPA is confronting and addressing as a part of the CompTox
11 program.

12 EPA's communication effort has focused on two areas. First is conveying the importance of the
13 approach and the value of the strategy to stakeholders including the public. Many in the regulated
14 community have worked at developing computational toxicology models of various kinds, often quite
15 specific to their products; they are, obviously, convinced of the strength of the approach or they
16 would not be pursuing it. If stakeholders are included in the process of development, validation and
17 application of these methods in a collaborative fashion, they may be more likely to accept the results
18 and provide constructive feedback. Second is providing the data to all stakeholders, including the
19 general public. The CompTox website (<http://www.epa.gov/ncct/>) is relatively easy to navigate, but it
20 would be useful to provide some information about strategies for extracting relevant data.

21 As EPA moves forward with the development of the CompTox program, communication can be
22 enhanced by being transparent about the limitations and uncertainties in the use of CompTox assays
23 to predict any particular endpoint in isolation and in combination with data from other CompTox
24 assays, and providing a broader understanding about what is known about a chemical's biological
25 activity based upon CompTox data in conjunction with Structure Activity Relationships (SAR), *in*
26 *vivo* testing, etc. It may also be useful to provide stakeholders with some summary statistics about the
27 results, perhaps along the lines of AOPs, with a transparent, easily accessible (e.g., on a website)
28 location for the details of the testing and the raw data. However, it should be kept in mind that
29 uninitiated evaluators of large datasets are often daunted by the sheer volume of data and may not
30 consider the quality and limitations of those data. As ExpoCast develops, the website

1 (<http://www.epa.gov/ncct/expocast/>) should incorporate estimates of exposure to chemicals and
2 mixtures (especially upper bounds if possible) potentially stratified by age, gender, regions of the
3 country, population density (rural, suburban, and urban), ethnicity and so forth.

4 Communication with epidemiologists and clinical investigators needs to be part of the process. It may
5 be difficult for some health scientists to discern the potential relevance of computational toxicology
6 to human exposure and health effects. Data generated and provided by EPA (and collaborators) can
7 be used to demonstrate that the tests utilized are relevant to human health effects. In addition, the
8 agency should clarify in what situations the data may fall short and be inadequate. For instance, there
9 is a higher level of uncertainty for specific AOPs, outcomes and/or for specific classes of chemicals.
10 Thus, it is essential to combine CompTox outputs with data on toxicokinetics, particularly
11 metabolism, of the chemical in humans. Finally, biomonitoring data, exposure pathways, chemical
12 source information and human activity patterns related to human exposure needs to be included in the
13 assessment of chemical risk.

14 The EPA should continue to partner with existing academic health science centers to disseminate
15 information on CompTox. The agency can utilize existing relationships via community outreach and
16 translation cores which support gene and cell therapy clinical trials and includes laboratories for basic
17 research, testing, scale-up, and clinical work. This would allow for the analysis of high-throughput
18 data and development of predictive modeling using CompTox data sets. As AOPs are developed, it
19 would also be useful for the agency to develop partnerships with relevant professional societies or
20 institutions. For example, a group within the EPA developing an AOP on asthma would benefit from
21 a partnership with the American Lung Association or the National Heart, Lung, and Blood Institute to
22 access physicians and researchers at the cutting edge in this field. The EPA also may benefit from
23 more collaboration with international agencies regarding data sources, data access and technology
24 transfer. Another important group of stakeholders are risk assessors and public health professionals in
25 state and tribal environmental and health agencies. Outreach to state and tribal public health scientists
26 would be helpful in informing them about the use of CompTox data in hazard identification and risk
27 assessment.

28 Some additional suggestions for research regarding communication and achieving a broader
29 understanding of the potential contributions and limitations of these approaches include the
30 following: (1) an evaluation of the pesticide stakeholder dialog process

1 (<http://www.epa.gov/oppfead1/cb/ppdc/#about>) by an independent expert (group) in communication
2 and stakeholder participation to see what can be learned from that experience; and (2) pursuing a
3 mental model study to compare expert and public understandings of how CompTox findings could be
4 informative (this might identify structural reasons why there might be communication difficulties and
5 how they could be addressed).

6 **2.5. Other Issues**

7 In addition to addressing the study questions, the SAB also identified several additional issues that
8 should be considered by the agency as it continues to develop the CompTox research program and
9 apply the program outputs.

10 1) The agency should clarify the goals and objectives for CompTox with respect to chemical
11 screening, prioritization and risk assessment. How will application of CompTox information improve
12 current EPA practice? Because risk assessments are conducted for a variety of purposes, demands on
13 the information base will necessarily differ among situations, but are there context-specific criteria for
14 when particular types of information are informative enough to be useful? Resolution of some of
15 these structural issues could be a useful contribution of the CompTox program even before it is
16 producing actionable information. The Deepwater Horizon provides an example of a programmatic
17 need – provision of information in emergency or other fast-moving settings – for which guidance is
18 lacking.

19 2) There is a need to better delineate what CompTox can and cannot contribute, both now and in
20 the future. Which contributions might be feasible over the next few years versus which ones will take
21 longer to develop? What is the extent of the universe of chemicals that will be evaluated (e.g.,
22 soluble? not too volatile)? What sort of health effects can be assessed at the current time and in the
23 future? The identification of critical pathways is an important step toward clarifying a number of key
24 risk challenges – mixtures, interactions with background exposures, existing conditions and
25 susceptibilities – and it provides an attractive possible approach for using CompTox data to assess
26 risk, but are there risks that may be obscured or ignored when an approach based on critical pathways
27 is used?

28 3) How well developed are EPA's capabilities for synthesizing and using fragmentary and
29 incomplete information? For the near term, CompTox results will be quite limited and their best use

1 likely will be in combination with limited information from other sources. Current EPA practice tends
2 to be chemical-specific and to focus on particular types of information. How far along is EPA in
3 developing multi-chemical and multi-factor risk assessments? A future vision for CompTox is that
4 the data will deliver a complete identification of critical pathways and a measure of the response
5 along them, but realizing such a vision is still remote. For some period of time, perhaps indefinitely,
6 the information provided by CompTox will be fragmentary and new methods will be needed for its
7 interpretation. The primary challenges thus are transitional – how to build analytic structures that can
8 incorporate new kinds of information in incremental steps.

9 4) Analytic capabilities are a major consideration for the CompTox program, but it is also
10 important to think about institutional capabilities for developing, organizing, and using the
11 information. Are data resources constantly updated and expanded and are there ongoing
12 improvements in accessibility and analytic flexibility? How can staff and scientist training and
13 development in use of new CompTox data be accomplished? Is there an institutional culture that
14 identifies opportunities for the use of new information and is vigilant to detect warning signs
15 concerning new issues and new difficulties? Is there good communication between groups that might
16 use the same or similar information and methods? Can the institutions develop and support
17 incremental changes? Can they engage stakeholders and other governmental and non-governmental
18 organizations as supporters of such change?

19 5) Critical data for steps in the transition from current risk assessment practices will only partly
20 come from CompTox; those data must be synthesized with other, more familiar, types of information.
21 Data needs and requirements for data quality must be addressed as well.

22 6) How will EPA handle the inevitable occurrence when future data from *in vivo* or human
23 studies contradict the ToxCast data? As the science moves forward, there may/will be results
24 generated from *in vivo* and/or epidemiologic studies that contradict or are not consistent with the
25 CompTox results. This is an inherent characteristic of science and is not unique to the CompTox
26 program. However, as inconsistencies occur how will EPA respond? What will be EPA's approach
27 to handling the comments and perceptions that are sure to arise questioning whether the CompTox
28 data either overestimated the risk of a chemical or did not identify the hazard(s) of a chemical? What
29 would the implications be for the CompTox program and the use of its outputs? The public is
30 bombarded with studies that show a risk for chemical X, and then other studies later show no risk,

1 and then another wave of additional studies again showing a risk. The EPA needs to be prepared for
2 the shifting playing field since future data from *in vivo* and human studies will not always be
3 consistent with the CompTox results. The inconsistency that evolves over time as new data are
4 generated is inevitable in scientific research, but EPA needs to develop a plan to address this as it will
5 definitely occur and its occurrence will accelerate as more of the results from CompTox testing
6 become available and begin to be used for prioritization and risk assessment.

7 7) It is clear that effective communication with all stakeholders, both within and outside the
8 agency, will be essential to the long term use of CompTox and ExpoCast findings.

9 8) There is a need to develop a community of scientists to provide feedback on ExpoCast in a
10 parallel fashion to ToxCast is needed.

11 9) Finally, the SAB recommends that the EPA consider establishing an ongoing external
12 advisory process to institutionalize a long term program built around the idea of incremental
13 transformation. This process should be free of members with financial ties to the program. An
14 independent perspective on the current program and prospects for the future can be provided along
15 with constructive suggestions. The potential for longer term engagement by an external advisory
16 committee should be considered.
